pleted records appear to be adequate for tests of dams for ability to transmit high fecundity.

The development and use of chicken inbreds, C. W. KNOX. (U. S. D. A.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 262-272).—The first part of this paper deals with the development of inbreds and the second part with the use of inbred lines in crosses in an attempt to produce progeny of superior value to the commercial poultry farmer. The extensive data tabulated and discussed indicate that lines of inbreds may be produced without a decrease of fertility, hatchability, mature body weight, or annual egg production. Selection must be initiated and maintained during inbreeding in order to control the direction that homozygosity takes during inbreeding. Incrossbreds produced from inbred Rhode Island Reds mated to Single-Comb White Leghorns gave superior results in annual egg production to the standardbred Rhode Island Reds and White Leghorns in this experiment. Incrossing and topincrossing were not as favorable for annual egg production as incrossbreeding, but were improving with each successive year that the inbreds improved, namely the last 3 yr.

Relative influence of heredity and environment on fertility and hatchability in Wyandottes, S. S. MUNRO (*Empire Jour. Expt. Agr.*, 14 (1946), No. 53, pp. 25-30).—The author discusses the findings of Hutt (E. S. R., 83, p. 181) with reference to a relatively low hatching rate of White Wyandotte eggs in certain locations, and presents data to show that "under certain conditions, the exact nature of which is obscure, this breed will give excellent reproductive results. It is further evident that excellent and sustained records of high hatchability on the part of a flock or a strain at any one poultry plant cannot be regarded per se as proof of genetic superiority in reproductive ability. It likewise follows that the converse, i. e., continued poor hatchability on the part of a flock at a single location cannot be regarded as genetic inferiority without further evidence."

The work reported included an exchange of pullets in the fall of 1940 between Lacombe, Alta., a point of consistently poor hatchability, and Summerland, B. C., with consistently high hatchability. Data collected in 1942 at Lacombe showed "conclusively that the two strains do not differ when the environmental conditions are equalized."

The suggestion is made that low fertility may not actually be the fault of the male or of the sperm, but may sometimes result from infertilizable eggs, or from very early death of the embryo either before oviposition or while the eggs are being held for incubation, so that the incubated egg appears infertile on candling or when broken out for examination.

The effect of selection for shank length on sexual maturity and early egg weight in Single Comb White Leghorn pullets, I. M. LERNER. (Univ. Calif.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 204-209).—Data on the interrelationships between body size, sexual maturity, and early egg weight in two lines of Leghorns primarily differing in shank length are presented. It is shown that selection for body size delayed sexual maturity and increased beginning egg weight. Within the line characterized by the smaller body size, age at sexual maturity and mean weight of the first 10 eggs show a significant net correlation, both being independent of body size. In the line with larger body size early egg weight is independent of maturity but is correlated with body size. The possible reasons for such difference between the two lines are discussed.

Rate of growth in progeny to ten weeks in relation to shank length of parents, M. A. JULI and E. W. GLAZENER. (Md. Expt. Sta.). (*Poultry Sci.*,

25 (1946), No. 3, pp. 256-261).—From the station flock of New Hampshires, two strains differing significantly in shank length at 10 weeks of age were developed by the original selection and progeny testing of parents differing in adult shank length. At this age a high positive correlation between body weight and shank length was demonstrated for both Barred Plymouth Rocks and New Hampshires. Variability in body weight was found to be from less than two to more than three times the variability in shank length. Variability in rate of growth was found to be relatively greatest at 4 weeks of age in females and at 4 to 6 weeks of age in males.

Since the two strains of New Hampshires differed significantly in body weight at 4 weeks of age, the most effective selection of birds for breeding purposes to effect differences in growth rates of progeny is thought to be on the basis of shank length and body weight at approximately this age.

Effects of thiouracil, desiccated thyroid, and stilbestrol derivatives on various glands, body weight, and dressing appearance in the chicken, E. W. GLAZENER and M. A. JULL. (Md. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 236-241, illus. 2).—In feeding trials with a total of 280 chicks, including purebred and crossbred Barred Plymouth Rocks and New Hampshires, feeding thiouracil at the 0.1 percent and 0.2 percent levels in the mash during the growing period depressed growth, the 0.2 percent level more than the 0.1 percent. Thyroid enlargement was relatively greater in the females than in the males, indicating a sex difference. Although the testes size in the thiouracil and diethylstilbestrol lots varied a great deal, the testes tended to be smaller in these lots, particularly in the diethylstilbestrol birds, than in the controls. Combs were small and pale for both sexes in the thiouracil and diethylstilbestrol lots, whereas the combs in the desiccated thyroid lot were a bright red.

On the basis of dressing and fleshing appearance, the lot of birds fed diethylstilbestrol for a 3-week period at a level of approximately 30 mg. per day gave the best dressing appearance of any of the lots. Early limited feeding followed by full feeding for the last 3 weeks seemed to improve the dressing appearance of the carcasses. Dimethyl ether of diethylstilbestrol fed for a 2-week period at the level of 50 mg. per pound of feed did not appear to improve finish, affect appetite, or improve the weight of the birds over the controls under the conditions. Combs and wattles of both males and females became pale and shriveled in the treated lots.

Tasting tests indicated that the diethylstilbestrol and dimethyl ether of diethylstilbestrol-fed lots, particularly the females, were more highly flavored than the controls, although much individual variation in taste was evident.

Regulation in the chick allantois, E. ZWILLING. ([Conn.] Storrs Expt. Sta.). (*Jour. Expt. Zool.*, 101 (1946), No. 3, pp. 445-453, illus. 9).—It was found that removal of the remains of the primitive streak from 18-25 somite chick embryos does not interfere with tail formation. Excision of the first formed posterior gut diverticulum (allantoic diverticulum) results in either entire absence of the allantois or the formation of small, usually atypical allantoides. The underdeveloped and multiple allantoic structures which are found are explained as the result of a regulation of remnants of the allantoic epithelium. This operation does not interfere with the formation of the caudal intestine.

The inheritance of egg production and hatchability in turkeys, W. O. WILSON and L. E. JOHNSON. (S. Dak. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 278-284, illus. 4).—Data on Bronze and Beltsville Small White turkeys in four different flocks were analyzed for heritability of egg produc-

tion and of egg hatchability. A total of 229 dams and 514 daughters was included.

The heritability of egg production and egg hatchability was not significantly different in the two varieties studied. Expressed on the basis of the first season's production records, the heritability of individual differences was +0.02 for egg production and +0.26 for hatchability. The intrayear, intra-flock correlation between egg production and egg hatchability was +0.08.

**Inheritance of hessian fly resistance derived from W38 and durum P. I. 94587, R. M. CALDWELL, W. B. CARTWRIGHT, and L. E. COMPTON.** (Ind. Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 5, pp. 398-409, illus. 2).—The authors present data on the inheritance of hessian fly resistance in the  $F_1$ ,  $F_2$ , and  $F_3$  of crosses of W38, C. I. 1261 (resistant), with Wabash, Fultz sel.-Hungarian selections, and Dawson (susceptible). The resistant W38 was shown to differ from the susceptible wheats studied by a single gene pair governing resistance. In the field, resistance tended to be dominant; in the greenhouse, it was usually recessive. The symbols  $H_3$   $H_3$  are proposed to designate the incompletely dominant gene pair controlling hessian fly resistance in W38, and  $h_3$   $h_3$  the allelomorphic gene pair occurring in the susceptible Wabash, Dawson, and Fultz-Hungarian selections. Resistance derived from W38 and its hybrid progenies is shown to have two expressions in resistant genotypes, viz, (1) the capacity under favorable conditions to suppress development of the fly larvae, with resultant normal plant growth, and (2) the capacity to grow almost normally and not to exhibit stunting under the conditions that prevent the full development of resistance and thus permit infestation. The second capacity was invariably associated with the first and may be used as a criterion of the presence of the  $H_3$   $H_3$  factor pair under greenhouse or high-temperature conditions. Limited data suggest that the hessian fly-resistant durum P. I. 94587 differs from the susceptible vulgare wheats Gladden and C. I. 11850 by at least two dominant genes governing fly resistance.

## FIELD CROPS

**High altitude forage investigations in southwestern Colorado, D. KOONCE** (*Colorado Sta. Bul.* 490 (1946), pp. 19+, illus. 4).—Forage crops experiments were conducted at the Fort Lewis substation 1937-44 under dry land and irrigation. Ladak surpassed other alfalfa varieties in average acre yield. Alfalfa averaged 3.98 tons of hay per acre under irrigation, alfalfa-grass mixture 3.91 tons, and all grass plots 0.54 tons. Seeding alfalfa at rates of 5 and 10 lb. per acre gave practically the same yields of hay 1938-41. Under irrigation, reed canary grass and crested wheatgrass were inferior to brome grass and orchard grass in the alfalfa-grass mixtures. Three irrigations of 6 acre-inches each, if applications were so delayed that the first cutting would receive one irrigation and the second cutting two, would produce good yields of hay without increasing the amount of water used. Stand, survival, and yield of alfalfa, brome grass, and crested wheatgrass in a non-irrigated forage and grazing test on bench land clearly indicated their importance in such pasture plantings. Animal preference in grazing and the amount of forage left slightly grazed showed that alfalfa, brome grass, and orchard grass were more palatable than crested wheatgrass or western wheatgrass. The mixture suggested by the results for planting on non-irrigated land, with conditions similar to those at Fort Lewis, includes alfalfa, 2 to 3 lb. per acre. brome grass 6 to 8 lb., and crested wheatgrass 5 to 7 lb.

**Judging mountain meadow range condition in eastern Oregon and eastern Washington.** E. H. REID and G. D. PICKFORD (*U. S. Dept. Agr. Cir. 748* (1946), pp. 31, illus. 18).—The general guides outlined by which the condition of mountain meadows can be judged, and tentative standards for determining proper utilization of mountain-meadow vegetation, are intended for those who use or manage summer range and who have such meadows in these and other western States. Proper management of mountain meadows and its benefits are treated in some detail.

**Dry-land pasture experiments at the Central Mountain Branch Station, Moccasin, Montana.** R. M. WILLIAMS and A. H. POST. (Coop. U. S. D. A.). (*Montana Sta. Bul. 431* (1945), p. 31, illus. 14).—Superseding Bulletin 388 (E. S. R., 85, p. 473), this publication includes three additional years of grazing data, but the final results and recommendations on the comparable value of standard crested wheatgrass, native grass, and smooth brome grass for pasture purposes remain practically the same.

**Length of life of roots of ten species of perennial range and pasture grasses.** J. E. WEAVER and E. ZINK. (Univ. Nebr.). (*Plant Physiol.*, 21 (1946), No. 2, pp. 201–217, illus. 6).—Seeds of these 10 grasses were planted in loam soil in containers large enough for ample root development. Small bands of very thin pliable sheet tin were placed around individual roots at each of two developmental stages of the plant, 3,424 roots of 181 plants being thus banded to ascertain their longevity. Of the banded roots of crested wheatgrass, 97 percent survived the first summer and 75 percent the first year. Survival on Hungarian brome grass was 92, 84, and 36 percent at three examinations; that on switchgrass and western wheatgrass was—after the second summer—100 and 42 percent. After three growing seasons, 81 percent of the roots on big bluestem survived, but none on nodding wild-rye. Losses in all species were gradual, and after three growing seasons survival of roots was for blue grama 45 percent, side-oats grama 14, and little bluestem and needlegrass 10 percent each.

The average number of roots produced by individual plants varied from 175 to 882 at the end of the third summer; compared with the total number, losses among the banded roots were small to negligible, often amounting to only 2 to 8 percent of the total number of living roots. Nearly all the species studied have a long life and exhibit great permanency of occupation—both important factors for preventing erosion. Roots of 6 species of unknown age were banded in clay loam soil in prairie; at the end of the second growing season the loss ranged from 23 to 45 percent each, except for needlegrass where it was 57 percent. Established seedlings of Hungarian brome and crested wheatgrass with banded roots were clipped at a 2-in. height and at 10-day intervals; there was no loss from unclipped controls of the first species and only 3 percent from the second, but roots of the clipped brome grass suffered a loss of 15 percent and those of the wheatgrass 73. New roots from vigorous transplanted blocks of sod of big and little bluestem grasses were banded and the tops of one lot of each were clipped at intervals of 10 to 14 days; after five clippings root losses were 45 and 64 percent, whereas the unclipped controls lost only 3 percent each.

**New alfalfa varieties resist wilt.** H. L. THOMAS (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, p. 11, illus. 1).—Ladak and Ranger are recommended for Minnesota because they have proved much superior to the old standard Grimm wherever bacterial wilt is a factor in depleting yields and stands.

**Blackeye beans in California, W. W. MACKIE** (*California Sta. Bul. 696* (1946), pp. 56, illus. 25).—The Blackeye, a cowpea of African origin with definite adaptation and edible qualities, more closely resembles the bean than any other legume. After becoming established in the Southern States, it spread to California where it was found well suited to the warmer irrigated areas and, to a lesser extent, to dry-farmed areas. Climatic conditions restricting common beans and lima beans do not apply equally to Blackeyes. Large areas in the San Joaquin and Sacramento valleys and in similar regions are well adapted to Blackeyes.

Methods of soil preparation, irrigation, cultivation, and harvesting—discussed in detail—are similar to those of other bean crops. Crop rotations with Blackeyes are more widespread and satisfactory than with other beans. Nodulation in Blackeyes is easily established and becomes permanent, although requiring a different culture from beans. Because of rainless summers, however, California almost exclusively holds the market for Blackeyes, limited almost entirely to the Southern States. Attacks of fungus and bacterial diseases and nematode and insect pests on the Blackeye have been largely met by the creation of disease-resistant varieties or by improving cultural practices under favorable weather conditions. Information on the price, production, and marketing of Blackeye beans and their uses and cooking practices is included, together with an extensive bibliography.

**Comparative development of some United States, Mexican, and Central American corns at different latitudes and altitudes, I. E. MELHUS, G. SEMENIUK, J. R. WALLIN, G. M. WATKINS, and G. J. GOODMAN.** (*Iowa Expt. Sta.*). (*Amer. Jour. Bot.*, 33 (1946), No. 3, pp. 220-221).—An abstract.

**Illinois hybrid corn tests, 1945, G. H. DUNGAN, J. H. BIGGER, A. L. LANG, B. KOEHLER, and R. W. JUGENHEIMER.** (*Coop. Ill. Nat. Hist. Survey*). (*Illinois Sta. Bul. 517* (1946), pp. 225-256, illus. 1).—Yields per acre and other agronomic characters are reported for 270 corn hybrids grown in 1945 on seven fields and 9 again grown on soils of two fertility levels. Sullivan test field again had the highest average yield, 91.7 bu. per acre. The fields averaged 60.1 bu. per acre compared with 46.5 bu., the State average. The 9 double-cross hybrids on the same farm at Urbana averaged 112.9 bu. per acre on highly productive soil and 66.3 bu. on medium-productive soil. White hybrids on southern fields performed relatively better than the whites on the northern and north-central fields. Lodging of corn was especially severe at Galesburg, mainly due to unfavorable weather; at Sheldon, insect damage (southern corn rootworm) and unfavorable weather; and at Alhambra, extremely late planting. The greatest amount of stalk breakage ascribable to damage by the European corn borer occurred at Sheldon. Losses from ear rots caused by *Diplodia* were low, but damage from *Nigrospora* was higher than usual. Seed of 18 hybrids treated with an organic sulfur compound yielded 8.7 bu. over untreated seed. Damage from kernel rot in these hybrids ranged from 1.13 to 5.84 percent.

**Cotton variety tests in Georgia, 1942-45, W. W. BALLARD, A. L. SMITH, and R. P. BLEDSOE.** (*Coop. U. S. D. A.*). (*Georgia Sta. Cir. 149* (1946), pp. 8).—Empire, Coker 200, Coker 100 Wilt, and Coker 4 in 1 were high in money value and with Hibred led in acre yields in north Georgia tests 1942-45. Empire strains and the above Coker strains also led in the 1945 tests. Coker 100 Wilt and Stonewilt led commercial varieties in yield and money value in south Georgia tests 1943-45. Lines of CSS 3720 surpassed other varieties in 1945 tests, and the wilt-resistant Empire 2910 outyielded other commercial varieties.

**Descriptions of and key to American potato varieties,** C. F. CLARK and P. M. LOMBARD (*U. S. Dept. Agr. Cir. 741 (1946), pp. 50, about 80 illus.*)—Potato varieties grown currently in the United States are discussed, and data for use in their identification are presented. Detailed descriptions based on plant, flower, tuber, and sprout characters are given for 39 varieties which are principally survivors of the many that originated in this country, largely during the second half of the nineteenth century, new varieties produced in the National potato-breeding program, and a few varieties from foreign sources. Their origin, seed stock production, and disease resistance are discussed, and a systematic key to the varieties is included. The main characteristics and present distribution of 14 less important varieties which are about to become extinct or have disappeared from commercial production but are still grown locally for home consumption are also given. There are 42 literature citations.

**Origin of the first European potatoes and their reaction to length of day,** J. E. VAN DER PLANK (*Nature [London], 157 (1946), No. 3990, pp. 503-505.*)—There are two centers from which potatoes might have come, viz, the Chiloé region of southern Chile and the Andes at tropical latitudes. The evidence presented from various sources (9 references) is believed "entirely consistent in showing that the first European potatoes were grown in short days, that they were in fact short-day varieties, and that short-day varieties persisted not just for a short while but for centuries." The Chilean varieties are generally regarded as long-day in reaction, and the evidence of photo-periodism is against the theory that European potatoes came from Chile. A brief discussion of the nomenclature is included.

**Origin of the first European potatoes and their reaction to length of day,** J. G. HAWKES and C. M. DRIVER (*Nature [London], 157 (1946), No. 3992, p. 591.*)—A comment on the authors' studies in relation to the above paper by van der Plank.

**Soybean varieties and dates of planting in the Yazoo-Mississippi Delta,** P. R. HENSON and R. S. CARR. (Coop. U. S. D. A.). (*Mississippi Sta. Bul. 428 (1946), pp. 12.*)—Variety tests 1944-45 at several localities in the Delta showed C101 and S100 to lead early maturing strains, Ogden the medium maturing, Volstate and Roanoke the medium-late maturing, and Mamloxi and Mamotan the late-maturing strains. Date of planting tests showed that soybeans may be planted from early April to early June with equally good results, and this long planting period should enable Delta farmers to fit soybeans readily into their planting schedules. The optimum combining period of the Ogden variety of soybeans can also be increased by early and late plantings.

**Preliminary observations on some effects of artificial defoliation of wheat plants,** R. M. WHITE (*Sci. Agr., 26 (1946), No. 5, pp. 225-229, illus. 1.*)—Grasshoppers are among the most widespread and persistent pests of cereals on the Canadian prairies; it is not uncommon for newly hatched hoppers to devour all the leaves of young plants. The question as to what effect this leaf removal actually has on the ultimate yield or quality of the grain led to this investigation, from which it was found that defoliation of the wheat plant—at any stage of development—did not necessarily result in crop failure. The yield suffered most when this occurred during the heading to dough stages; defoliation during the 2 weeks previous to maturity was not injurious to the plant insofar as yield was concerned. Defoliation of the growing plant affected the quantity and weight of the grain per bushel but not its quality.

**Better wheat for New York**, H. H. LOVE and W. T. CRAIG. (Coop. U. S. D. A.). (*New York*) *Cornell Sta. Bul.* 828 (1946), pp. 27, illus. 11).—Features of the program of wheat improvement aimed at the production of varieties high in yield and possessing winter hardiness, stiffness of straw, and resistance to disease, as well as the quality desired for particular purposes and their importance in the improvement program, are considered briefly. New varieties developed and introduced to the growers include Yorkwin (Dietz  $\times$  Goldcoin), Nured (Forward  $\times$  Dietz), Cornell 595—[(Howard  $\times$  Forward)  $\times$  Nured]  $\times$  Honor and Valprize (Valley  $\times$  Grandprize).

Seeding tests suggested about September 15 and on certain fields somewhat earlier for better yields. Data 1930-43 indicated that about 10 mo. are needed to produce a crop of winter wheat. Experiments over a number of years with spring grains show that spring wheat does not compare satisfactorily with winter wheat where the latter can be grown, and that oats and barley usually give better results.

**Seed inspection**, F. A. McLAUGHLIN (*Massachusetts Sta. Control Ser. Bul.* 127 (1945), pp. 40).—Purity, weed seed contents, and germination percentages are reported for official samples of seed of field crops and seed mixtures and germination for samples of vegetable seed collected in Massachusetts during the year ended November 1, 1945. Reports are also made on field tests for trueness to type and variety on lots of beans, beets, carrots, corn, and spinach, in conjunction with G. B. Snyder; and on germination and performance tests of flower seeds, by C. L. Thayer and E. B. Risley.

**Weed investigations**, C. A. BROWN and W. H. CARTER (*Louisiana Sta. Bul.* 402 (1946), pp. 24, illus. 7).—Characteristics and distribution of alligatorweed (*Alternanthera philoxeroides*) are described, and the progress of experiments on the control of this and other weeds by chemical and hormone herbicides and alligatorweed by farm machinery, including burners, is reported on. A high percentage of the alligatorweed plants was killed in tests with 2,4-D, and most of the plants were so weakened that they recovered slowly. While eradication was not obtained, the results seemed promising. Many other weeds, including nutgrass, cocklebur, ragweeds, rosebriar, water-hyacinth, and the rice weeds indigo, redweed, mulc-ear, and several sedges were also killed by 2,4-D or at least weakened.

**Destroying lawn weeds with 2,4-D**, G. H. AHLGREN and H. R. COX (*New Jersey Stat. Bul.* 725 (1946), pp. 11, illus. 4).—Tests with 2,4-D during the spring, summer, and fall of 1945, including comparisons of the relative effectiveness of ammonium and sodium salts of 2,4-D and of 2,4-D dissolved in carbowax, were made on all of the common lawn weeds and on some of lesser significance. Concentrations ranging from 0.14 to 0.56 percent of 2,4-D were applied, and effects on weeds and on lawn grasses are reported. Such broad-leaved turf weeds as dandelions and buckhorn could be destroyed easily by spraying with 2,4-D. Dandelions and buckhorn were successfully eliminated by spring, midsummer, and fall applications of 2,4-D, concentrations of 0.14 percent 2,4-D being adequate. Heavier concentrations were needed to destroy certain other weeds. The 2,4-D destroyed weeds more slowly in cool weather than during hotter periods. A spreader or wetting agent applied with the 2,4-D increased the ease with which more resistant waxy-leaved plants, as red sorrel or clover, can be destroyed. Kentucky bluegrass was more resistant to 2,4-D than is Chewing's fescue or Colonial bentgrass, although all of these grasses, cut at lawn-mower heights, withstood applications of 2,4-D as concentrated as 0.56 percent, which likewise had no herbicidal effect on crabgrass. Lawns and other turfing areas where crab-

grass exists should be treated to destroy the broad-leaved weeds in late August or September, which will prevent increased infestation by crabgrass. After treatment to eliminate the weeds, the area should be fertilized and reseeded. Minimum injury to clover resulted from use of a dilute concentration of 2,4-D and one containing no wetting agent. Certain weeds, as spotted spurge, were not destroyed by 2,4-D. Susceptible weeds were completely destroyed in 10 days to 3 weeks.

**Dandelion control with 2,4-dichlorophenoxyacetic acid (2,4-D),** D. KLINGMAN (*Wyoming Sta. Bul.* 274 (1946), pp. 13, illus. 3).—The tests reported indicated that dandelion could be eradicated almost completely by 2,4-D spray without harm to bluegrass, although white clover might be injured. Best results have been obtained where conditions favor rapid growth of grass, i. e., when daily temperatures average about 60°F. Home-made preparation gave good results by dissolving in water at a concentration of 1 part 2,4-D to 1,000 parts of water by weight (1/10 of 1 percent).

**Controlled grazing eradicates bindweed,** L. M. STAHLER and A. E. CARLSON. (Coop. U. S. D. A.). (*Minn. Farm. and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 12-13, illus. 2).—Controlled grazing by sheep can consistently eradicate bad stands of field bindweed in 2 yr. or less, according to results obtained in experiments at the Lamberton station. The routine found best is to plow the infested field and seed rye or winter wheat September 15; begin pasturing as soon as the grain has a good start and pasture until June 30; plow and seed immediately to Sudan grass which can be grazed until September 15, when the first-year routine is repeated. A project at Underwood for control of leafy spurge by grazing definitely established that spurge is highly palatable and nonpoisonous to sheep, which prefer the young stems and blooming heads to legumes and grasses. The flock also made normal gains on a bluegrass-leafy spurge mixture. Controlled grazing of bluegrass pasture heavily infested with leafy spurge reduced stands of spurge 54 percent the first year and 85 percent in 2 yr. Vigor of remaining plants was greatly reduced.

## HORTICULTURE

**A vegetable gardener's handbook on insects and diseases,** W. H. WHITE and S. P. DOOLITTLE (*U. S. Dept. Agr., Misc. Pub.* 605 (1946), p. 30+, about 70 illus.).—This revision of an earlier publication (*E. S. R.*, 90, p. 804) presents in a like manner general information on the important disease and insect pests of cultivated vegetables with information on control. Suggestions are given on the preparation of sprays and dusts, poisoned baits, etc., and on essential equipment.

**Savory herbs: Culture and use,** M. S. LOWMAN and M. BIRDSEYE (*U. S. Dept. Agr. Farmers' Bul.* 1977 (1946), pp. 33+, illus. 17).—General information is presented on the nature, growing, and utilization of various plants whose leaves, roots, flowers, or seeds are used for garnishing or flavoring. Included are such plants as anise, dill, parsley, chive, fennel, mint, sage, and thyme.

**USDA-34: A tropical sweet corn,** R. E. HARPER (*U. S. Dept. Agr., Agr. in Americas*, 7 (1946), No. 4, pp. 74-75, illus. 1).—Sweet corn varieties grown commonly in continental United States were found unadaptable to Puerto Rico due to differences in day length as well as susceptibility to plant disease.

This article discusses the development by the Puerto Rico Federal Experiment Station of USDA-34 sweet corn, a variety comparing favorably in

quality with continental varieties and resistant to several serious disease and insect pests. USDA-34 has become widely distributed in southern latitudes, including Hawaii, Latin American countries, and certain southern States.

The effect of various ions on guttation of the tomato, G. J. RALEIGH. (Cornell Univ.). (*Plant Physiol.*, 21 (1946), No. 2, pp. 194-200).—Bonny Best tomato plants grown in complete nutrient solutions until they had attained an approximate height of 130 cm. were then transferred to solutions lacking in one nutrient element such as N, P, K, Ca, or Mg. When deficiency symptoms became apparent, the plants were removed from the greenhouse to a humid underground chamber maintained at a temperature of 68° to 74°F. and the deficient elements were added to their respective cultures. The addition of nitrates to a N-deficient solution resulted in a marked guttation. Presumably the supplying of nitrate to such plants caused an increase in respiration. Plants supplied nitrate guttated profusely in a shorter time than did those supplied ammonium N, suggesting that the nitrate may have also provided oxygen. Marked guttation occurred also in the plants supplied P or K. Guttation did not occur in the plants in deficient solutions or in those supplied with Ca or Mg.

Hybrid tomatoes give superior yields, T. M. CURRENCE (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 4-5, illus. 2).—The author points out the possibilities of increased production, both early and total, of certain varietal combinations over ordinary commercial kinds. The chief limitation to date has been the painstaking and tedious procedures required in emasculation of blooms. However, some progress has been made in the development of varieties which, because of a structural variation, do not self-pollinate readily. Progress is reported in the selection of parental varieties that offer possibilities in hybrid seed production.

"Frost line" orcharding risky business; elevation and air drainage essential, W. S. CLARKE, JR. (*Pennsylvania Sta. Bul.* 475 (1946), Sup. 1, pp. 9-10, illus. 3).—Presenting information on frost damage to the station and nearby orchards in the spring of 1945, the author discusses various factors such as elevation, slope, air drainage, etc., that are involved in frost injury or its prevention. The selection of sites is considered so important that prospective planters of fruit trees are urged to study their locations carefully.

The organic acids of grapefruit juice, W. B. SINCLAIR and D. M. ENY. (Calif. Citrus Expt. Sta.). (*Plant Physiol.*, 21 (1946), No. 2, pp. 140-147, illus. 1).—The organic acids of grapefruit were found to be citric and malic acids, and the total acid content precipitated from grapefruit juice by lead acetate was equal to the sum of these acids. The titration curve of grapefruit juice was very similar to that of a pure citric acid solution, provided a correction is made for the combined acid occurring naturally in the juice. There was a definite relation between the pH and the amount of acid in the salt or combined form.

The free acids decreased and the pH of the juice increased with increase in size of fruits. The decrease in free acid concentration associated with enlargement is due chiefly to increased fruit size rather than any change in the absolute amount of free acid per fruit.

The alkalinity of the ash is a measure of the base-forming capacity of the juice as well as a measure of the cations combined with the organic acids. In grapefruit juice more than 50 percent of the total cations are utilized in the formation of organic acid salts, as compared to more than 70 percent in the juice of Valencia and navel oranges. A large increase in available

cations from soil fertilization would produce a limited increase in combined acid and little decrease in juice acidity.

Chile's expanding citrus industry, P. L. GUEST and G. ROSENBERG (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 6-7, pp. 98-100, 107, illus. 4).—A comprehensive discussion is presented of the extent, present status, cultural practices, and methods of harvesting and marketing. Citrus is grown over a north-south air line distance of more than 1,300 miles. At present production is confined largely to oranges and lemons, with 58 percent of the total in lemons.

Dominican coffee, R. P. STOVALL (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 5, pp. 87-89, 90, illus. 3).—Introduced in the early part of the eighteenth century, coffee is now one of the most important commodities produced in the Dominican Republic. Information is presented on location of the plantations, methods of culture, habits of growth, harvesting, marketing and official regulations, etc.

Effects of potassium on the nitrogenous constituents of *Ananas comosus* (L.) Merr, C. P. SIDFRIS and H. Y. YOUNG. (Pineapple Res. Inst. Hawaii). (*Plant Physiol.*, 21 (1946), No. 2, pp. 218-232, illus. 1).—Determination of the nitrogenous fractions in the tissues of pineapple plants supplied with equal amounts of N either as nitrate or ammonium, but on sharply contrasted K levels, showed that K supply affected N uptake. Nitrate N, as indicated in the basal leaf and stem sections, was greater in the high than in the low K cultures in the nitrate series. Ammonium N, generated possibly by deaminizing processes, occurred in traces in the plants of both nitrate and ammonium series. Ammonium absorbed from nutrient solutions was readily converted into compounds of greater complexity in the roots, and it is considered doubtful if any passed from roots to stem unchanged.

Soluble organic N calculated as milligrams per gram of fresh weight was higher in the low K than high K cultures of the nitrate series, but when calculated as total soluble organic N per plant the values were reversed. Protein N in the leaves calculated as milligrams per gram of tissue was greater in the low K than high K cultures, but in the stem these values were reversed.

The physiological function of K in the conversion of the soluble organic N fractions to protein N in high K cultures was more noticeable in the stem than in the leaves, where protein N was higher in the low than high K series.

The home lawn, H. L. LANTZ, L. C. GROVE, and E. P. SYLVESTER (*Iowa Sta. Bul.* P80 (1946), pp. 645-664, illus. 6).—Directions are given on building a new lawn by soil drainage and fertilization, seedbed preparation, and correct seeding; and caring for an established lawn by fertilizing, liming, rolling, mowing, watering, and control of earthworms, ants, and other insects. The recommendations on weed control deal with 2,4-D, weeds killed by 2,4-D compounds, how and when to spray them, effects on white clover, and precautions in using 2,4-D sprays.

Planting and caring for the lawn, G. H. AHLGREN (*New Jersey Stat. Bul.* 724 (1946), p. 32, illus. about 30).—General information is presented on the preparation of the soil, fertilizing, seeding, management of new and established lawns, weeding, watering, control of insect and other pests, etc.

## FORESTRY

The southern hardwoods (*Memphis: South. Hardwood Prod.*, [n. d.], pp. 46+, illus. 20).—Information is presented on the distribution, growth, wood, and uses of various species of hardwoods growing in southern forests.

## DISEASES OF PLANTS

Outstanding diseases of agricultural crops and uses of fungicides in the United States, S. E. A. MCCALLAN (*Contrib. Boyce Thompson Inst.*, 14 (1946), No. 3, pp. 105-115).—"A tentative method is presented for determining the importance of the disease loss on an over-all or national basis. An index is obtained from the product of the logarithm of the estimated annual percent loss . . . and the logarithm of the farm value expressed in units of \$100,000. A table is given of the 50 leading agricultural crops of the United States together with the farm value, acreage and farm value per acre, as well as the 5 leading States. The 36 outstanding diseases obtained by the above procedure are recorded, together with average annual loss, 10-yr. range in fluctuation, and present major control measures. Tables are also presented showing the estimated annual consumption of fungicides by chemicals and by crops and diseases. From this the more outstanding potential uses may be seen for new or improved fungicides, and hence the diseases for which it is desirable to develop test methods. Among the outstanding diseases where need for better fungicides are indicated are: (1) Seed treatments—corn and cotton seedling blights and oat smuts, [and] (2) sprays and dusts—apple scab, potato tip burn and late blight, peach and cherry brown rot, pear blight, peanut leaf spot, and tomato blights. More or less adequate laboratory or greenhouse methods for fungicide evaluation are available in certain of the cases cited, while development and standardization is necessary for most other important diseases."

Some features of the spread of plant diseases by air-borne and insect-borne inoculum, E. E. WILSON and G. A. BAKER. (*Univ. Calif.*). (*Phytopathology*, 36 (1946), No. 6, pp. 418-432, illus. 5).—Numerical data on the spread of diseases from infection to above-ground parts of nearby susceptible plants were compiled from the literature, and the rate at which the incidence diminished with increasing distance from the source of inoculum was examined. The diseases were of three categories with respect to mode of dissemination, viz, (1) fungus diseases spread by air-borne spores, (2) a bacterial disease spread by wind-blown rain, and (3) virus and fungus diseases spread by insect vectors. In each case the lowering in incidence of infection at increasing distances from the source was described to a fair degree of accuracy by an equation of the form  $y = 100(1 + a)^2 / (x + a)^2$ , where  $y$  is the incidence of infection at  $x_2$  and subsequent distance intervals expressed as a percentage of the incidence at  $x_1$ , or first distance interval. The quantity  $a$  depends on the conditions under which spore dissemination occurs as well as upon the location of  $x_1$  with respect to distance from the source. The results from use of this equation compared favorably with those from equations deduced by more complicated methods drawn from the literature.

Aerobiology in relation to plant disease, E. C. STAKMAN and C. M. CHRISTENSEN. (*Minn. Expt. Sta.*). (*Bot. Rev.*, 12 (1946), No. 4, pp. 205-253).—This critical review (151 references) considers the subject under adaptation of fungi to aerial dissemination; quantities of spores and devices facilitating their production; spore wastage; liberation of spores; spore size; altitudes reached by spores and the rate of fall and theoretical dispersal distance; local dissemination of fungi; long-distance dissemination; stem rust of wheat (discussed in great detail); rusts of oats and leaf rusts of wheat in the United States; cereal rusts in Europe, North Africa, and India; the distance to which viable spores can be carried by winds; and dissemination of physiologic races of plant pathogens. "Even where a disease, as such, may

persist in a certain region from year to year independently of wind-borne spores from another region, as late blight of potatoes in New England or wheat stem rust in some of the Northern States where barberries still are present, interregional wind dissemination of certain virulent physiologic races may still play a very important part in epidemiology. More precise evidence of this has been accumulated with certain of the cereal rusts than with other plant pathogens, but the principle very probably applies to other plant pathogens also."

**Nuclear cycle and life history of a new species of *Doassansia* (Ustilaginales),** M. J. THIRUMALACHAR (*Lloydia*, 9 (1946), No. 1, pp. 24-30, illus. 12).—The new species of smut fungus—*D. hygrophila*—described was found parasitizing the leaves of *Hygrophila* sp. in India.

**Manganese toxicity affecting crops on acid soils,** J. B. HALE and S. G. HEINTZE (*Nature [London]*, 157 (1946), No. 3991, p. 554).—During the past 5 yr. the authors have investigated some 25 cases of damage to field crops which have proved on analysis to be associated with a very high concentration of Mn in the leaves; soil analyses always revealed a very low pH and a high concentration of exchangeable Mn. The evidence available seems to confirm the view that in acid soils Mn toxicity is an important factor in causing injury to plant growth. Ca deficiency may occur on some acid soils, but in only one of these cases of excess Mn was there indication of such a condition.

**Detection of manganese deficiency in plants by tissue tests, using tetramethyldiaminodiphenylmethane,** D. J. D. NICHOLAS (*Nature [London]*, 157 (1946), No. 3995, p. 696).—The above reagent was successfully used in detecting traces of Mn in plant tissue extracts; the detailed procedure is given.

**Nickel and multiple trace element deficiencies in agricultural crops,** W. A. ROACH and C. BARCLAY (*Nature [London]*, 157 (1946), No. 3995, p. 696).—In studies of mineral deficiencies, the yields of wheat, potatoes, and broadbeans sprayed with solutions containing compounds of Mn, Fe, B, Cu, Zn, and Ni, respectively, were all increased. This is believed to be the first indication that Ni is important in increasing crop yields and also the first record of Zn deficiency in the British Isles.

**Glyoxalidine derivatives as foliage fungicides, I, II** (*Contrib. Boyce Thompson Inst.*, 14 (1946), No. 3, pp. 151-171, illus. 4).—The following two papers are included:

I. *Laboratory studies*, R. H. Wellman and S. E. A. McCallan (pp. 151-160).—Since—in laboratory tests—they combine high fungistatic action with low toxicity to plants, 2-heptadecyl-, 1-hydroxyethyl-2-heptadecyl-, and 1-aminoethyl-2-heptadecylglyoxalidine or imidazoline show considerable promise as foliage fungicides. In slide-germination tests, maximum fungistatic action was achieved with glyoxalidine derivatives having a straight chain substituent containing 13 to 17 C atoms in the 2-position. Addition of lead arsenate or summer oil in proportions used in the field did not interfere with the fungistatic action. Maximum phytotoxicity in the greenhouse was reached with the 11 to 13 C atom derivatives. The ratio of highest concentration giving no plant injury to the LD50 value for 1-hydroxyethyl-2-undecylglyoxalidine was 13.5 and for 1-hydroxyethyl-2-heptadecylglyoxalidine 1,450. Side-chain unsaturation increased the phytotoxicity as did increasing length of chain in the 1-position. In the greenhouse, these materials were injurious to tomatoes at concentrations which would not control late blight but were moderately effective against snapdragon rust without phytotoxicity. There are 16 references.

II. *Field studies*, H. W. Thurston, Jr., J. B. Harry, F. H. Lewis, A. B. Groves, and C. F. Taylor (pp. 161-171) (Pa., W. Va., and Va. Expt. Stas. et al.).—Three derivatives, 1-hydroxyethyl-2-heptadecylglyoxalidine (No. 337), 2-heptadecylglyoxalidine (No. 341), and 1-aminoethyl-2-heptadecylglyoxalidine (No. 630)—investigated in the laboratory—have been tested in the field during several years against black spot of rose, apple scab and rust, potato late blight, and cherry leaf spot. On roses (1 year's test) 2-heptadecylglyoxalidine at 3 lb. per 100 gal. gave black spot control equivalent to bordeaux with wetting agent, and with less conspicuous deposit; 1-hydroxyethyl-2-heptadecylglyoxalidine was less effective and somewhat injurious. In 5-yr. tests in Pennsylvania on McIntosh and Stayman apples, 1-hydroxyethyl-2-heptadecylglyoxalidine and 2-heptadecylglyoxalidine at 1 lb. and 1-aminoethyl-2-heptadecylglyoxalidine at 3 lb. per 100 gal. controlled apple scab equivalent to standard lime-sulfur and much better than Fermate at 3 lb.; 1-hydroxyethyl-2-heptadecylglyoxalidine caused some foliage injury at 3 lb. per 100 gal. 2-Heptadecylglyoxalidine at 1 lb. per 100 gal. produced consistently better appearing foliage with greater area per fruit spur than standard lime-sulfur and had a marked residual effect on control of scab on the leaves. The glyoxalidine derivatives had much steeper dosage response slopes than Fermate in the field. Against cedar-apple rust, 2-heptadecylglyoxalidine was fairly effective but not equal to Fermate. 2-Heptadecylglyoxalidine was compatible with acid lead arsenate, nicotine sulfate, excess hydrated lime, and summer oil. In accordance with the laboratory results, these glyoxalidine derivatives caused potato leaf injury and failed to control late blight. In 4-yr. tests in Pennsylvania and Virginia and 2-yr. tests in West Virginia, 2-heptadecylglyoxalidine on Montmorency sour cherries at 1 lb. per 100 gal. was the most effective compound tested for control of leaf spot defoliation; there was little or no leaf injury and no dwarfing of fruit.

Polymeric organic polysulphides as fungicides and spray adjuvants, W. D. STEWART and J. H. STANDEN (*Contrib. Boyce Thompson Inst.*, 14 (1946), No. 3, pp. 203-220, *illus.* 3).—Polymeric organic polysulfides of high molecular weight can be made as stable finely divided aqueous dispersions with a range in particle size of  $1\mu$  to  $4\mu$ ; these are especially suitable for use as spray materials. Sprayed on plants, these latices dehydrate to form rubbery nonphytotoxic films insoluble in water and oil and of unusual tenacity and resistance to weathering. On admixing with other spray materials tenacity and resistance to weathering are imparted to the spray deposit. The polymers were evaluated as fungicides by standard laboratory procedures against *Sclerotinia fructicola* and *Alternaria solani*, polymeric organic polysulfides proving fungicidal. Toxicity to fungi increased with increase in the S content of the polymer. Activity was associated with the solid or polymer phase of the latices; the aqueous phase was almost nontoxic. Polyethylene pentasulfides are considered the most feasible for commercial use. Latices of these polymers were field-tested in 1945 with modern high-pressure spray equipment. The polymers were more effective at 2 lb. per 100 gal. as protective sprays against apple scab than micronized sulfur at 10 lb. per 100 gal. under conditions of high and frequent rainfall. Latices of this polymer applied in mixed sprays enhanced the activity of toxicants. The build-up of spray deposits was rapid even with high and frequent rainfall, but the physical compatibility with standard fungicides and insecticides—oil included—was excellent.

Seed and seedling infection of barley, brome grass, and wheat by *Xanthomonas translucens* var. *cerealis*, J. R. WALLIN. (Iowa Expt. Sta.). (*Phyto-*

*pathology*, 36 (1946), No. 6, pp. 446-457, illus. 4).—Seed and seedling infection of barley, bromegrass, and wheat was investigated with seeds infested by races of this bacterium. The factors studied were length of the period during which the seeds were soaked in bacterial suspension, hulling and wounding of the seeds, and the temperatures during seed infestation, germination, and growth; the localization and penetration of the bacteria into the developing plumule were also observed. Hulled barley proved far more susceptible to invasion than the nonhulled. The temperature during seed infestation of nonhulled barley failed to influence seed germination or seedling disease. The temperature during seed germination and seedling development, however, influenced emergence and seedling infection when seeds were infested with race 1 of the pathogen. Infection of barley, bromegrass, and wheat seedlings was facilitated by rupturing the testa covering the embryo prior to seed infestation. Diseased seedlings were obtained from infested hulled barley and bromegrass seeds that had been planted in the soil. A few diseased seedlings also developed from nonwounded infested wheat seeds. The bacteria were found to penetrate through wounds in the pericarp covering the embryo; infection of the plumule occurred through wounds or stomata on the coleoptile. The bacteria spread rapidly through these tissues and into the enclosed foliage leaves. Since the first foliage leaf is adjacent to the coleoptile, it became infected before emerging from the coleoptile. The infected leaf, by elongation, carried the bacteria into the aerial parts of the seedling.

Blight of oats caused by an *Helminthosporium* differing from the one producing leaf spot, H. R. ROSEN and H. W. LARSH. (Univ. Ark. et al.). (*Amer. Jour. Bot.*, 33 (1946), No. 3, p. 223).—An abstract.

Reactions of oat varieties and selections to four races of loose smut, E. D. HANSING, E. G. HEYNE, and T. R. STANTON. (Kans. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 36 (1946), No. 6, pp. 433-445, illus. 1).—The four physiologic races of loose smut reported upon were collected in Kansas; two of them (A and D) were distinct from those reported by others. Race A is characterized by susceptibility of the Fulghum and Monarch varieties and resistance of Canadian; race D, by susceptibility of Richland and Victoria and resistance of Fulghum. Of the commercial varieties, Kanota and Fulghum were susceptible to race A, Richland and Columbia to B, and Richland, Columbia, and Otoo to C. Richland, Boone, Cedar, Tama, Fultex, Vicland, Florilce, and Traveler were susceptible to race D; Columbia and Forvie were intermediate; Ventura and Osage were susceptible in the greenhouse but intermediate to moderately resistant in the field; and Benton, Clinton, Fulton, Mission, and Goldwin had some resistance to this new race. Black Mesdag, Large Hull-less, Red Rustproof, Navarro, Markton, Bruncker, Bond, New Nortex, Neosho, Bonda, Mindo, and several promising hybrid selections were highly resistant to all four races: Neosho appears promising as a parent for oats crosses, being highly resistant to smut, resistant to the common races of crown and stem rusts, and having desirable agronomic characters. Neosho was distributed in Kansas in 1945.

Flag smut of wheat in Mexico, N. E. BORLAUG, J. G. HARRAR, and E. C. STAKMAN (*Phytopathology*, 36 (1946), No. 6, p. 479).—*Urocystis tritici* was first observed in Mexico on April 27, 1945, in an area of about 10 sq. miles near Zitacuaro. The fungus was apparently introduced on wheat from Australia originally intended for milling. Since most of the wheats grown in Mexico are susceptible, eradication, local quarantine, and seed treatment were instituted as protective measures.

**Étude biologique de *Puccinia graminis* Persoon (rouille noire des graminées).** L. GUYOT (*Compt. Rend. Acad. Sci. Paris*], 222 (1946), No. 10, pp. 566-568).—The results of a study of the physiological races of the wheat stem rust fungus *P. graminis tritici* in continental France are presented, along with a survey of the hosts—wild and cultivated—in that country, and a classification of the varieties of wheat in relation to their susceptibility to infection.

**Why does grain spoil in storage?** M. MILNER (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 1, 13-14, illus. 1).—On the basis of a 30-yr. investigation of grain spoilage and heating in storage by this station, the author briefly summarizes the causes with special reference to molds and moisture content and the essentials of good storage conditions.

**Resistance of beans to halo-blight and anthracnose and the occurrence of bean-mosaic and bean-weevil.** W. D. REID (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 4, Sect. A, pp. 331-335, illus. 1).—During the 1943-44 and 1944-45 seasons in New Zealand 72 varieties embracing 137 lines of dwarf and runner beans were tested for resistance to halo blight; attack by bean mosaic and bean weevil was also recorded. No one variety proved immune to halo blight and anthracnose, though all white-seeded and runner varieties were highly resistant to both; with few exceptions, varieties also exhibited an equivalent susceptibility to the two diseases. While the foliage and pod susceptibilities of a variety were usually of the same order, this was not true in all cases. Only 8 lines were infected with mosaic, and of these 6 were from recently imported seed; some lines showing the virus infection in previous years were now free from it. Records of field infestation with bean weevil suggested that varieties are widely different in susceptibility; the white-seeded and runner varieties had little or no infestation.

**Spermogonia versus pycnidia in *Mycosphaerella brassicicola*.** W. C. SNYDER. (Univ. Calif.). (*Phytopathology*, 36 (1946), No. 6, pp. 481-484, illus. 1).—Though a pycnidial stage of *M. brassicicola* has been described, only randomized ring spot lesions have been noted on infected leaves in the field; this suggests that all inoculum is wind-borne rather than partly water-borne. Inoculations of detached leaves were successful only with ascospores, never with ooze from the so-called pycnidia, nor was it possible to start cultures or obtain germination of the spores composing the ooze. Because of failure of the "pycnospores" to germinate, grow, or produce infection on cabbage under conditions favorable to ascospore growth and infection, as well as because of their characteristic small size and appearance, it is concluded that they are spermatia rather than pycnospores, and that the structures in which they are borne are spermogonia. In single-ascospore cultures both spermogonia and perithecia were obtained, showing the fungus to be homothallic.

**Preliminary note on the use of ammonium molybdate to control whiptail in cauliflower and broccoli crops.** K. J. MITCHELL (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 4, Sect. A, pp. 287-293, illus. 2).—The majority of cauliflower and broccoli crops grown in the North Island (New Zealand) Services Vegetable Production projects contained a proportion of the plants showing very distorted growth and giving very poor yields; this malformation has been termed "whiptail." Insofar as known, the trouble had not previously been reported by commercial growers and their crops appeared to be normally free from it. Experimental study indicated that it can be controlled by dressings of 20 lb. or less per acre of  $(\text{NH}_4)_2\text{MoO}_4$ . A heavy application (1 ton per acre) of blood-and-bone fertilizer gave a 60 percent re-

duction in the number of affected plants. An application of 4 tons of  $\text{CaCO}_3$  per acre immediately before setting out of cauliflower in one test gave no apparent control, but where in addition 3 cwt. of KCl per acre were used there was considerable—though not significant—reduction in the number of plants affected.

Parasitism of *Striga* sp. on *Dolichos lablab* Linn., F. W. ANDREWS (*Nature* [London], 157 (1946), No. 3990, p. 515).—A preliminary note on the parasitism of *Striga* on the roots of *D. lablab*.

The effect of depth of planting on the emergence and survival of blue lupine, P. DECKER. (Fla. Expt. Sta.). (*Phytopathology*, 36 (1946), No. 6, pp. 479–480, illus. 1).—The loss of seedling plants from *Rhizoctonia* spp. is said to be serious in the growing of blue lupine as a winter cover crop in Florida. Greenhouse plantings resulted in 94.1 percent emergence after 5 days for seeds sown 1 in. deep as compared with 54.7 percent after 10 days for seeds sown 2 in. deep; 3 weeks after sowing, 70.7 percent of the plants were growing for the first group, as compared with only 6.5 percent still alive for the latter.

Why less disease in Irish potatoes in 1945? Eastern North Carolina lost heavily in '43 and '44 but had very little disease loss in 1945, J. H. JENSEN (*Res. and Farming* [North Carolina Sta.], 4 (1946), Prog. Rpt. 2, p. 11, illus. 1).—The much warmer March–April in 1945 than in 1943–44 favored seed piece sprouting and establishment of healthy vigorous stands, and the death of young plants from root and stem rots—favored by cold soils—was small. In May–June of 1945 the weather was much cooler than in 1943–44; this held in check the two most serious diseases of the State—southern bacterial wilt and southern root rot.

A type of internal necrosis of the potato tuber caused by psyllids, W. C. SNYDER, H. EARL THOMAS, and S. J. FAIRCHILD. (Univ. Calif. et al.). (*Phytopathology*, 36 (1946), No. 6, pp. 480–481, illus. 1).—White Rose potato tubers artificially infested with large numbers of psyllids [*Paratrioza cockerelli*] exhibited—after 6 months' storage—an internal discoloration consisting of discontinuous dark flecks distributed almost throughout the tuber. Before becoming completely necrotic these flecks were observed microscopically to contain dark smooth spherical bodies of variable size in some cells within the fleck. It is concluded that under certain conditions a type of internal necrosis may occur as a tuber symptom of psyllid yellows.

Host parasite relations in pink rot of potato, N. H. WHITE (*Jour. Austral. Inst. Agr. Sci.*, 11 (1945), No. 4, pp. 195–197).—In this study, three distinct zones were recognized in potato tubers partly invaded by *Phytophthora erythroseptica*, viz, a zone of living uninvaded tissue, one of invaded but living tissue in which the fungus behaves as a true parasite, and a zone of invaded but dead tissue giving a characteristic pink coloration when exposed to  $\text{O}_2$ , and in which the fungus lives as a saprophyte. Color changes in the dead zone are due to the tyrosinase reaction which is a post-mortem oxidase reaction resulting from the mixture of cell metabolites in the presence of  $\text{O}_2$ . When *P. erythroseptica* invades the tuber tissue the presence of the intercellular mycelium increases the permeability of the host cells and causes a degradation of the phosphorylated compounds leading to decompensated respiration and finally the death of invaded tissues. The mechanism by which the fungus alters the permeability of the cells remains, however, unknown.

Some laboratory and field data on ring-rot of potatoes in California, P. A. ARK. (Univ. Calif.). (*Amer. Potato Jour.*, 23 (1946), No. 4, pp. 170–181).—The ooze test—observation of the masses of bacteria coming out of

the diseased tissue in water mounts under the low power microscope—was successfully used in California for diagnosing ring spot of potato; it is considered a presumptive test. Incubation of seed pieces harboring the pathogen in a suitable substratum—such as peat moss or soil at 28°C.—revealed the disease in 3 weeks; this may prove helpful in ridding foundation stock of ring rot. Proper disinfection of contaminated tools is to a high degree impeded by the slime present in infected tubers. Under California conditions, bacterial soft rot is often secondary to ring rot, and probably black-leg may also be secondary to it.

Seed and soil treatment for the control of potato scab, L. A. SCHAAL. (U. S. D. A.) (*Amer. Potato Jour.*, 23 (1946), No. 4, pp. 163-170).—Treatment of seed and soil with certain chemicals proved of no value in controlling scab infection in irrigated sandy soils of northern Colorado; these soils had produced several crops of heavily scabbed tubers previous to the tests. Treatment of such soils with  $\text{HgCl}_2$ ,  $\text{Al}_2(\text{SO}_4)_3$ , KI, S, yellow oxide of mercury, or sulfamic acid failed to reduce scab infection, but treatment of infected seed tubers with  $\text{HgCl}_2$  reduced the number of infected tubers over the infected nontreated seed. When S was added with manure to the scabby soil 3 weeks before planting and again to the opened furrow at planting time, scab infection for the current and two following seasons was not reduced. None of the seed or soil treatments appeared of value for control of scab in the alkaline soils of northern Colorado; even treated clean seed produced scabby tubers in the scab-infested soil.

Ecology of the eelworm cyst, C. ELLENBY (*Nature [London]*, 157 (1946), No. 3988, pp. 451-452, illus. 1).—When cysts of the potato root nematode *Heterodera rostochiensis* are stimulated with potato root excretion, larvae begin to emerge after a delay of some days, the number emerging per day increases steadily, reaches a maximum, and then declines even though the cysts are freshly stimulated; finally no more larvae emerge, although the cysts still contain large numbers of eggs, and larvae will again emerge when the cysts are again stimulated after an interval of time. This stopping and later resumption of emergence is experimentally shown to be caused by factors operating within the cyst as a unit, and the cessation is believed to be due to an inhibitor. Clearly the eggs constitute an ecological community, and the behavior of individuals in it affects the behavior of the others. The possible influences of alterations in pH or of enzymes within the cysts are discussed on the bases of experimental results here briefly summarized.

Sugar-beet mosaic in New Zealand, R. E. F. MATTHEWS (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 4, Sect. A, pp. 294-302, illus. 7).—The author reports a mosaic disease occurring spontaneously on sugar beets. It is characterized by a mosaic mottling of the leaves; a study of the symptoms, methods of transmission, host range, and physical properties of the virus indicates it to be caused by the sugar beet mosaic virus ( $\beta$  virus 2 of K. M. Smith). Its incidence is summarized, and methods of spread and overwintering are discussed.

Verslag van het serologische onderzoek betreffende de vergelingsziekte der suikerbieten 1942-1943 [Contribution to the serological investigation of the yellows disease of sugar beets, 1942-43], H. L. BOOIJ, M. P. DE BRUYN OUBOTER, M. C. CREMER, and E. VAN SLOGTEREN ([*Netherlands Lab. Bioembollen Onderzoek, Lisse*, No. 73 (1944), pp. 28+, illus. 7).

The present sugarcane disease situation in Louisiana, E. V. ABBOTT. (U. S. D. A.) (*Sugar Bul.*, 24 (1946), No. 17, pp. 129-130, illus. 1).—Curves showing the percentage of Louisiana sugarcane acreage in disease-resistant

varieties during 1928-45 render apparent the marked progress since 1930 in developing varieties with greater resistance to mosaic, root rot, and stubble deterioration. The detailed results are discussed briefly.

**Response of sugarcane to the hot-water treatment, P. H. DUNCKELMAN, W. J. LUKE, R. T. GIBBENS, and C. W. EDGERTON** (*Louisiana Sta. Bul. 401 (1946), pp. 37*).—In tests over a 5-yr. period to determine the effectiveness of hot-water treatment, seed cane was submerged in hot water at 52°C. for 20 min. before planting. Replicated plots were set with treated and untreated seed cane on nine plantations, and plantings were made in August, September, October, and November. The chlorotic streak virus in the stalks was completely destroyed or inactivated by this treatment, which also stimulated growth of the buds and young shoots and resulted in better stands than with the untreated seed cane. No significant differences in the sucrose content of the cane were observed in plots planted with treated vs. untreated seed cane. In the August plantings, differences in yields between the two groups were small. In the September, October, and November plantings, however, material increases in yield were obtained with several varieties in the plots planted with treated seed cane. With such varieties as C. P. 29/320 and C. P. 28/19, these increases were 2.5 to 4.5 tons per acre of plant cane; smaller but significant increases were also obtained with the stubble crops. Even though a few varieties failed to show significant increases in yield, it would appear that with most varieties the profits to the planter would be increased by treating the seed cane.

**Occurrence of curly-top virus in meristematic tissue, C. F. LACKEY.** (U. S. D. A.) (*Phytopathology, 36 (1946), No. 6, pp. 462-468, illus. 2*).—This virus had previously been found to multiply and be translocated only in the host phloem; in parenchyma tissues it occurs in relatively low concentrations or not at all. The author here reports multiplication of the virus in meristematic tissue. Methods were designed to cut 0.4- to 0.5-mm. sections of beet and bean root tips below the protophloem sieve tubes. When these sections in a 5 percent sucrose solution were fed to nonviruliferous leafhoppers via a specially designed feeding cage, positive results were obtained in all of 22 tests. Direct feeding of leafhoppers on single living root tips in which only a 0.5-mm. length was exposed resulted in infection in 3 of the 7 tests made. When sections of bean root tips were similarly used, infection was obtained in all of 15 tests. When the bark was peeled off from Turkish tobacco and *Nicotiana glutinosa*—thus removing the external phloem and leaving a thin layer of cambium tissue—and scrapings of cambium from short sections of the stems were fed to leafhoppers, high percentages of infection were obtained from young severely diseased tobacco plants and less infection as the plants became older and started to recover. The author discusses the occurrence of these high concentrations of virus in meristematic tissues in the absence of apparent injury.

**Plant nutrition in relation to disease development.—III, Fusarium wilt of tomato, J. C. WALKER and R. E. FOSTER.** (Univ. Wis.). (*Amer. Jour. Bot., 33 (1946), No. 4, pp. 259-264, illus. 3*).—This part of the investigation (E. S. R., 94, p. 347) considers the relation of nutrition to fusarium wilt development in infected young tomato plants grown in sand in the greenhouse and supplied with solutions containing varying concentrations of all elements used. Within the experimental limits, disease development in susceptible or intermediate resistant hosts grown at optimum temperature for wilt decreased with increases in nutrient concentration regardless of the degree of virulence of the pathogen or the age of the plants. With use of graded

concentrations based on the Hoagland-Snyder series (E. S. R., 72, p. 625), increased nutrient concentration up to the 2H level occasioned an increased diffusion pressure deficit in cells of uninoculated plants. Growth of either the host or the pathogen alone was low in the 0.1H solution, reached a maximum in the 1H nutrient, and decreased with further increase in total salt concentration. Unbalanced nutrition caused an alteration in susceptibility to wilt which was not correlated with total plant growth. Studies of the effect of nutrient balance on disease development revealed that infected plants receiving a low concentration of K or a high concentration of N exhibit an increasing wilt development. Solutions low in N or high in K induced a decrease in disease severity.

Interpretation of resistance to fusarium wilt in tomato, W. C. SNYDER, K. F. BAKER, and H. N. HANSEN. (Univ. Calif.). (*Science*, 103 (1946), No. 2685, pp. 707-708).—The experimental results reported appear to justify the conclusions that resistance is not localized in the root system, the substance responsible for it is not present in inhibitory amounts in the xylem stream, resistance originates in the living tissues of the plant and the material causing it does not migrate or diffuse into the xylem vessels, and field resistance to infection functions in living cells of the roots through which the fungus (*Fusarium oxysporum* f. *lycopersici*, a soil organism) must pass to become a vascular pathogen. The Bonny Best and Pan America tomato varieties were used in the study. Resistance in the latter is apparently a direct function of the cellular protoplasm of the plant similar to that of cabbage; it appears to be present but not localized in the root system and does not operate in the xylem.

Identity and known distribution of *Elsinoë piri* in Washington and Oregon, A. E. JENKINS, M. J. FORSELL, and L. W. BOYLE. (U. S. D. A.). (*Phytopathology*, 36 (1946), No. 6, pp. 458-461, illus. 2).—The recent finding of *E. piri* on apple and pear in western Washington and Oregon is of special moment in view of the economic importance of the susceptible fruit crop in the United States. West of the Cascade Range—as shown in a map—the disease was found in a special survey as follows: On apple in 7 counties of Washington and in 10 of Oregon, on pear in 3 counties of Washington and 1 of Oregon, and on quince in 1 county of Washington. Only the conidial (*Sphaceloma*) stage was observed. Typical spotting on leaves and fruit is illustrated.

Boron deficiency in apples—observations at New England Experiment Farm, J. A. HOLBECH (Agr. Gaz. N. S. Wales, 57 (1946), Nos. 1, pp. 17-21, illus. 5; 2, pp. 75-80, illus. 3; 3, pp. 192-196, illus. 3; 4, pp. 184-188, illus. 2).—In 1937—as a result of extensive investigations by the Department of Agriculture, New South Wales—certain recommendations were made concerning the use of borax for the control of internal cork. Further needed studies were continued at the New England Experiment Farm; the results of these later observations are here considered, including the growth and fruit symptoms and the classification of the latter into superficial cork, cork, internal cork, and corky core. Data on varietal susceptibilities are also presented. Trials of borax added to the soil indicated 1 lb. per tree to be effective and the results probably to last for 5 yr.; the most suitable time of application for this area was during June-August. A distinct advantage from hoeing the borax into the soil immediately after application was shown in the reduction in percentage of corky fruit. The findings indicated that where fruits were suffering from B deficiency, their keeping quality was greatly improved by the treatment, and the condition and life of the fruits in cold storage were not adversely affected except when excessive amounts of B were applied to the

case. Finally, the author considers the damage due to use of excessive amounts of B, the "measles" condition of the Delicious variety, and detailed recommendations for borax treatment.

Living to apicent leaves from fluorine deposit, E. R. DE ONG (*Phytopathology*, 36 (1946), No. 6, pp. 401-421, illus. 1).—Fluorine deposited on apricot trees from an aluminum reduction plant resulted in a characteristic type of foliage injury. The growing tips appeared unaffected, but wilting developed on the edges of the leaf when 2 to 3 weeks old and became progressively more pronounced for about 10 days, when the tissue was brown and dead. The central part of the leaf usually remained unaffected; the dead margins weathered away, often leaving the central uninjured part of the leaf still intact. There was much gumming of the young twigs, and gum pockets developed on the trunks of some of the 5-year-old trees. Defoliated areas 5 to 16 in. long were observed on the older twigs. The degree of injury varied with type of soil, and the effects were intensified by lack of rain. Injury was most pronounced within 2 miles of the reduction plant and to a decreasing degree up to 8 miles to the windward side. After closing of the plant, new growth became normal within 3 weeks. The fluorine content ranged from 247 to 403 p. p. m.

Some aspects of the aerial dissemination of spores, with special reference to conidia of *Sclerotinia laxa*, E. E. WILSON and G. A. BAKER. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 72 (1946), No. 9, pp. 301-327, illus. 5).—Conidia of *S. laxa*—cause of a blossom blight of stone fruits—are produced in large numbers during late winter on blossoms and twigs affected the previous spring. These are detached by low-velocity winds and, judging from their rate of fall in still air, are readily transported by air currents. Spread through apricot orchards via airborne conidia northward from well-defined sources of spore, has been observed. For three disease gradients studied in 1939 the mean levels of blossom infection in trees 22, 44, 66, and 88 ft. from the nearest source trees were 39, 21, 12, and 6.5 percent, respectively, of the level in source trees; for four gradients studied in 1940 the corresponding values were 55.5, 10, 28, and 23. The mathematical treatment of these data minimized or eliminated the effects of such factors as the number of spores produced and liberated at the source, the length of the dissemination periods, and variations in the environal conditions that initiate infection. For this reason, an explanation of the difference between the 1939 and 1940 gradients was sought elsewhere. In 1939 and again in 1940 there was only one period at the susceptible blossoming when the direction of the wind favored spore dissemination northward. During the 1940 period mean wind velocities were 1.88 times higher than during the 1939 period. The amount of blossom infection was assumed to be proportional to the number of spores reaching the blossoms, and the ultimate characteristics of the gradients were judged to be expressions of variations in the aerial density of spores during the effective dissemination periods. Factors capable of disturbing the relations between disease incidence and aerial density of spores are discussed.

Variations in aerial density of spores with increase in the distance from their source were studied by releasing *Lycopodium* spores and catching them on grass slides placed 5, 10, and 15 ft. downwind from the point of release; the density varied approximately in inverse proportion to the square of the distance from the source. According to other tests the over-all distribution of these spores along the vertical and horizontal axes of intercepting planes followed roughly that of normal probability. The standard deviations of the

distributions were therefore employed to express the degree of dispersion at various distances from the source; these values increased approximately in proportion to distance from source. At equivalent distances, however, the standard deviation for horizontal distributions ( $\sigma_h$ ) were consistently greater than those for vertical distributions ( $\sigma_v$ ). When spores were released 7.5 ft. from the ground, the mean  $\sigma_h/\sigma_v$  ratio proved to be 1.55, a value very close to the 1.59 obtained by others in measuring the amplitude of the horizontal and vertical components of air turbulence. Studies of the dispersion of small puffs of ammonium chloride "smoke" gave similar results. The effect of leafless trees on the vertical dispersion of spores was also studied. The rate at which aerial density of spores decreased with increases in distance from the source was apparently not affected by variations in wind velocity between 2 and 16 miles per hour. For winds below about 5 miles per hour, however, dispersion at a given distance from the source was often greater than that for medium and high velocity. Between medium and high velocities, on the other hand, dispersion varied little within the 5 to 15 ft. studied. Since frictional turbulence increases with wind velocity, aerial dispersion of spores should likewise increase, other things being equal. The degree of dispersion at a given distance from the source, however, is determined by the rate the spores are dispersed in relation to the rate they are carried downwind. On the whole, the experimental results indicate that dispersion increased at about the same rate as wind velocity except below about 5 miles per hour; further study of this point is deemed desirable.

To compare the results from observations on disease spread with those from the experiments, the latter were generalized in terms of dissemination (1) from a three-dimensional block source instead of from a "point" source, (2) through orchard trees instead of over open ground, and (3) for distances up to 100 ft. instead of 15 ft. Certain gaps were bridged by assumptions, which, if rendered untenable by further studies, can be modified. Though the results of this treatment must remain provisional, the observed spread of the disease through the apricot orchards is described to a good first approximation by an equation of the form  $y = A/X^p$ , where  $y$  is the ratio of the percentage of blossom infection in a vertical slice of susceptible tissue (blossom) at a horizontal distance from the source block to the percentage of blossom infection in the source trees,  $A$  and  $p$  are constants depending on wind velocity and perhaps to a lesser extent on other quantities, and  $x$  is the horizontal distance from the center of the nearest source trees. There are 20 references.

**Eradicating stunt diseased bushes, C. A. DOEHLERT.** (N. J. Expt. Stas.). (*Cranberries*, 10 (1946), No. 12, pp. 24-25).—Preliminary tests of a spray of Ammate, Prestol, and nicotine sulfate appeared to meet the requirements of (1) killing by a contact spray all the insects on the blueberry plant to prevent further transmission, (2) killing the foliage quickly to prevent further feeding, and (3) killing the tops and roots to render unnecessary further observations on the plant. Spraying with 2,4-D failed to destroy the foliage.

**Search for an insect carrier, W. W. TOMLINSON, JR.** (N. J. Expt. Stas.). (*Cranberries*, 10 (1946), No. 12, p. 11).—Preliminary to tests for suspected vectors of the virus blueberry stunt disease, the author reports trying out about 2 doz. leafhoppers swept from blueberry bushes throughout the summer on an exclusive blueberry plant diet, those surviving for 2 weeks being deemed active blueberry feeders and therefore possible vectors. Several other insects were similarly tested.

A note on banana leaf speckle in Jamaica and some associated fungi, E. B. MARTYN (*Imp. Mycol. Inst., Mycol. Papers No. 13 (1945), pp. 5+, illus. 3*).—The author found that in Surinam the most conspicuous form of "speckling" was due to *Chloridium musae*. Another fungus, weakly parasitic on the leaf, is here described as *Cladosporium musae* n. sp. A third fungus constantly found growing epiphytically on the under surface of the leaves and especially near the margins is here described as *Zygophiala jamaicensis* n. gen. and sp. Besides the last, the related fungus *Zygosporium oscheoides* has also been encountered on leaves from one or two localities.

The unknown disease of the coconut palm in Jamaica, R. LEACH (*Trop. Agr. [Trinidad], 23 (1946), No. 3, pp. 50-60, illus. 8*).—In the past a serious disease of coconut palms in Jamaica had been considered the same as bronze leaf wilt in Trinidad; it is believed from the findings of this study that the two are distinct. Until the cause of the Jamaica disease is determined the author is referring to it as the "unknown disease" of coconuts. The symptoms are described in some detail and compared with those of the bronze disease. The growth of the leaves, nuts, and spathes of healthy and diseased palms was recorded throughout the year. The disease has affected palms far more in the wet than in the dry season, the trees apparently being more susceptible when growth is stimulated. Possible causes are referred to briefly. The author believes that it may be associated with a facultative root parasite but that soil conditions are the main controlling factor inasmuch as they affect the nutritive status of the trees. It is suggested that investigations should be confined largely to studying the etiology of the disease on very young seedlings which are known to succumb on certain soils; such plants are much more easily handled than the larger trees.

Seasonal changes in biological equilibria involving two chondriosomal systems in variegated *Hosta*, M. W. WOODS and H. G. DU BUY. (*Univ. Md. et al.*). (*Phytopathology, 36 (1946), No. 6, pp. 472-478, illus. 4*).—White variegated areas of the plantain lily were found due to colorless plastids which, under certain conditions, multiplied at rates differing from the normal plastids in cells containing both types (heterochondric cells). In leaves formed during spring or fall the variegation-inducing plastids apparently suppressed the multiplication of normal plastids in heterochondric cells, the leaves becoming strongly variegated; the reverse was true during summer, when "masking" of symptoms occurred in successively formed leaves. The vascular tissues of the leaf exerted an influence on adjacent mesophyll of such a nature that multiplication of normal plastids frequently seemed to occur at the expense of the variegation-inducing plastids in heterochondric cells, regardless of season. The bearing of these results on cancer and virus problems is discussed.

Further field observations on fused needle disease of pines, W. NEILSON-JONES (*Empire Forestry Jour. [London], 24 (1945), No. 2, pp. 235-239, illus. 1*).—Continued observations (E. S. R., 88, p. 496; 92, p. 182) of field experiments at Wareham Forest (England) over a 9-yr. period indicated that application of compost in the presence of adequate phosphate at sowing time almost entirely prevented the development of the fused-needle disease in *Pinus contorta*. Similar applications to a 9-year-old stand already exhibiting 60 percent of affected trees reduced the incidence 50 percent during the course of 5 yr. Basic slag alone led to definite amelioration, but its effect was apparently not lasting.

Interim report on trials of copper naphthenates and mercuric naphthenates as wood preservatives, A. G. V. BERRY (*Empire Forestry Jour. [Lon-*

don], 24 (1945), No. 2, pp. 233-235).—The authors report very promising results with wood specimens treated with these metallo-organic salts dissolved in gas oil and applied as solutions to specimens of wood by the open tank process and exposed under rigorously destructive tropical conditions for almost 6 yr. Besides the tests with the metallic naphthenates, 10 pieces of white pine were impregnated with gas oil only, this being identical with that used as a solvent for the naphthenates; results here were so good as to confuse the tests with the gas oil-dissolved naphthenates, and further trials are being made.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

Experimental analysis of methods for measuring small mammal populations, L. F. STICKEL (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 150-159, illus. 3).—The number of *Peromyscus leucopus* caught by snap traps in the central acre of a 17-acre study area represented the population of this central unit plus surrounding acres. By currently accepted methods of interpreting snap-trap data, the population per acre would be considered as 23 adults, but these data indicate that the true population was between 6 and 7 adults per acre. Modern methods of live-trapping are shown to be valid for population studies; two methods are presented for the conversion of such data into per acre figures. Errors involved in the current use of snap-trap data are discussed, and snap-trap methods are shown to be invalid for determining actual population numbers. It should, however, be practical to use a snap-trap quadrant technic for obtaining a relative measure or index figure for small mammal populations. There are 20 references.

Soil-fertility standards for game food plants, S. A. WILDE. (Wis. Expt. Sta. et al.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 77-81).—Surveys of forest soils and vegetation in Wisconsin have indicated that many important fruit-bearing trees and shrubs have a greatly restricted quantitative distribution; by reason of their contents in vitamins and other functional substances they may be essential in wildlife welfare. A detailed study was started in 1944 of the soil requirements of a few species for use in future artificial propagation. The present paper attempts to express some environal conditions in terms of concrete data on species for artificial propagation and their soil fertility requirements in nurseries and in the field. As to the silvicultural aspects of planting for game, one way to avoid certain European experiences would be to build the forest with all its natural associates from the plant and animal kingdoms and not merely as a barren framework of lumber. The introduction of some secondary trees and shrubs might have a greater indirect silvicultural influence than a direct bearing on game management.

The effect of mating time upon reproduction in foxes, C. K. GUNN (*Empire Jour. Expt. Agr.*, 13 (1945), No. 52, pp. 193-198, illus. 3).—Data from the same group of 274 vixens—analyzed by two methods—indicated that mating in the early period of estrum gives a higher production rate (i. e., average litter size of all mated vixens) than when mated late in estrum. No significant difference in average litter size was found between early- and late-mated groups of vixens later proving gravid. Statistical analyses gave no significant difference between the average litter size of 132 vixens mated during their first day of estrum and 80 mated on the second day. Similarly—using the vaginal smear test—no real difference was found between the average litter size of the early group of 43 vixens mated during proestrus and 73

mated during the early cornified-cell stage. A significant increase in the number of nonpregnancies after mating occurred in third- and fourth-day matings compared with matings on the first and second days of estrus. The findings—analyzed on a basis of the vaginal smear test—confirmed these results. The estrus period in foxes was found by both test methods to vary in duration from 1 to 4 days, with exceptional cases extending to 5 or 6 days.

A comparison of carotene and vitamin A utilization by the fox, C. F. BASSETT, L. E. HARRIS, and C. F. WILKE. (Cornell Univ. et al.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 16-24, illus. 1).—Thirty-four fox pups and their dams were put on a 14-day vitamin A-deficient diet beginning when the pups were 21 days old. When 35 days old the pups were allotted at random to 6 experimental groups in each of 2 series. All received the same vitamin A-low basal diet throughout the experiment and, in addition, those in series 1 received supplemental amounts of vitamin A and those in 2 received carotene fed at levels of 0, 15, 25, 50, 200, and 600 International Units per kilogram of body weight per day. The pups were weaned when 49 days old. Blood samples were taken by cardiac puncture at about the middle and end of the experiment to determine the vitamin A content of the blood, and all test animals were killed at pelting time and the liver was removed, ground, and analyzed for vitamin A. The findings indicated that the fox can utilize carotene as a source of vitamin A, but less efficiently than the vitamin per se. Until further data are available it is thus recommended that growing foxes be fed 100 to 600 I. U. (360  $\mu$ g.) of carotene per kilogram by body weight per day; it is believed probable that a smaller amount of carotene and possibly of vitamin A also can be fed when more data are available.

Bone growth as an age criterion in the cottontail rabbit, H. P. THOMSEN and O. A. MORTENSEN. (Univ. Wis.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 171-174, illus. 1).—This preliminary report indicated that young-of-the-year can be differentiated from adult cottontails by X-raying the bones or by staining them to show the presence or absence of epiphyseal cartilage. This cartilage persists in the shoulder regions of some rabbits (presumably the latest-born) until January, and probably in the earliest-born through November—when most rabbits are taken by hunters. Further verification is needed of the safe terminal date for age classification by various bones.

Calculating poison bait mixtures, T. I. STORER. (Univ. Calif.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 177-180, illus. 2).—Whenever a quantity of any bait is to be prepared, some calculations are necessary unless the amount is exactly that of an available formula. More elaborate calculations are needed if it is desired to change a formula or to compare two or more. Much time may be saved in these and similar problems by use of a nomogram with which—knowing the values of any two items—the third may be quickly calculated; the chart presented and discussed has been prepared to facilitate such calculations.

Evaluating rat baits by field acceptance trials on Guam, W. D. CRABB and L. O. EMIK. (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 162-171, illus. 4).—Various baits were evaluated against a standard bait of plain rolled oats, usually the criterion of significance of difference between mean acceptances; rolled oats was repeatedly demonstrated the cereal of choice. Three oily bases proved superior as adjuvants to the cereal in the following order: Ground fresh copra, copra oil, and peanut butter; the optimum ratio of copra to rolled oats lay at 1 : 4 to 1 : 6. Replications of trials gave important additional evidence: Significance of differences became more reliable as the degrees of freedom attributable to error increased; the validity of

using interaction as the error term in single trials was substantiated by analysis of replications.

*Alaria taxideae* n. sp., from the badger and other mustelids, G. SWANSON and A. B. ERICKSON. (Minn. Expt. Sta. et al.). (*Jour. Parasitol.*, 32 (1946), No. 1, pp. 17-19, illus. 7).—This new species of fluke from Minnesota is described from the adult stage.

New host records for the trombiculid mite *Acariscus masoni* Ewing, D. S. FARNER and E. A. SEAMAN (*Jour. Parasitol.*, 32 (1946), No. 1, p. 93).—A brief note.

Observations on the tropical rat mite *Liponyssus bacoti* as an ecto-parasite of laboratory animals and suggestions for its control, T. A. OLSON and R. G. DAHMS (*Jour. Parasitol.*, 32 (1946), No. 1, pp. 56-60).—In April 1945, a heavy infestation of this mite occurred on hamsters, rats, and mice in a medical laboratory animal house in Texas; the hamsters were particularly susceptible, and several died. Rats, mice, and guinea pigs placed in infested cages after a dead hamster had been removed died in a short time, apparently as a result of exsanguination rather than disease or toxic effects. A trial application of DDT to small amounts of infested bedding (wood shavings) resulted in good control; general treatment of the animal house based on this information proved effective for at least 1.5 mo. and had no ill effect on rats or hamsters but was toxic to mice. During the first 24 hr., 30 percent of the ♀ mice in the breeding colony died. Although only two young mice had died by the third day, a large loss took place during the following 11 days; it is believed that this anomalous result should be ascribed largely to the early loss of ♀♀, many of which were nursing the young at the time of their death. Adult ♂ mice appeared more resistant, since all survived. Observations of living mites during the study showed that engorged ♀♀ laid two to eight eggs within a 34-hr. period; these sometimes hatched within 24 hr. or less, and the six-legged larvae—though receiving no blood meal—transformed into first-stage nymphs within 1 to 2 days.

New records of *Macracanthorhynchus hirudinaceus* in Sciuridae, R. RAUSCH. (Mich. State Col.). (*Jour. Parasitol.*, 32 (1946), No. 1, p. 94).—The fox squirrel and chipmunk are reported parasitized by *M. hirudinaceus*. That the fox squirrel seems a satisfactory host for this roundworm is considered important, since it could serve as a reservoir host for infection of pigs.

A redescription of *Physaloptera limbata* Leidy, 1856 (Nematoda: Physalopterinae), B. B. MORGAN. (Univ. Wis.). (*Jour. Parasitol.*, 32 (1946), No. 1, pp. 69-71, illus. 3).—This roundworm is redescribed from parasitized moles and shrews collected from several States (Wis., Mo., Ind., Ohio, Kans., Iowa, Md., Vt., N. H., and Ill.).

Significance of racial variation in birds to wildlife management, J. W. ALDRICH (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 86-93).—A general discussion based on current knowledge (12 references) of bird species and races and on the significance of races to wildlife management—with examples.

General notes (*Auk*, 63 (1946), No. 2, pp. 245-246, 248-249, 260-261).—Of special interest to economic ornithology are Avian Leukosis and the Great Black-Backed Gull, by M. Hare; Death of a Trumpeter Swan From Multiple Parasitism, by I. M. Cowan; and Predation on Living Prey by the Black Vulture, by A. Sprunt, Jr.

Evidence of trans-Gulf migration, G. H. LOWERY, JR. (La. State Univ.). (*Auk*, 63 (1946), No. 2, pp. 175-211, illus. 1).—For many years ornithologists have been agreed that vast numbers and many kinds of land birds migrate

straight across the Gulf of Mexico each spring and fall. Recently the existence of this trans-Gulf fly way was denied on theoretical grounds; consequently, further direct field investigation became desirable. This paper is concerned chiefly with the preliminary results of such a study.

Scores of records of 62 species seen crossing the Gulf of Mexico during the migration period are now available. The intentional nature of these crossings is demonstrated by the fact that all except one of these birds were proceeding in the seasonal direction of migration. Trans-Gulf flights of tremendous magnitude are indicated by the exact parallel between the phenomena of migration over the Gulf coast regions and over the Gulf itself, by observations of low-flying migrants seen from land at the beginning or end of their trans-Gulf journey, and by the high flight densities over the coast of Yucatán in spring as revealed by telescopic studies. All evidence adduced by others to show that land birds migrate exclusively by coastal routes is believed compatible with the theory of trans-Gulf migration, properly understood. There are 36 references.

**Summer birds of the Okoboji region, 1938-1942, R. L. KING** (*Iowa Acad. Sci. Proc.*, 51 (1944), pp. 467-470).—A list of the birds observed in this Iowa area is presented.

**A preliminary report on the food of ducks at Reelfoot Lake, Tennessee, R. J. SCHOFFMAN** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 10-13).

**Further use of wood duck nesting boxes in Wheeler Wildlife Refuge, P. BRYAN** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 76-77).—Further notes on the utilization and permanence of the 98 nesting boxes reported upon previously (*E. S. R.*, 93, p. 597).

**Age and sex criteria and weights of Canada geese, W. H. ELDER.** (*Ill. Nat. Hist. Survey*). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 93-111, illus. 14).—Of 2,179 Canada geese weighed on an Illinois wintering ground, only 6 and these ♂♂—exceeded 10 lb. Among weights of 1,028 live geese handled in banding studies, juvenile ♀♀ averaged 6.5 lb., juvenile ♂♂ 7.5 lb., and adult ♂♂ 8.4 lb. There was a highly significant difference between weights of juveniles and adults of both sexes and between weights of ♂♂ and ♀♀ at any age. Comparison of November-December with January-March weights indicated a significant loss in weight at the close of the hunting season, when crops provided for geese on a refuge were completely exhausted, indicating that the carrying capacity had been exceeded and that the sporadic winter feeding was inadequate. This condition may affect the fecundity of adults and determine how soon a young goose starts to breed. The simplest and most reliable criterion for distinguishing first-year geese is said to be the notch in the tips of the tail feathers. The tail molt is continuous and centrifugal through the winter. Various other types of plumage variation were examined, but most of them were too infrequent or present in all age groups. Methods were devised for cloacal examination and instruments constructed to facilitate it and to measure bursal depth. The penis of the juvenile ♂ does not exceed  $3 \times 10$  mm. in size and is said to be an absolutely reliable age criterion. In the ♀♀ the opening of the oviduct into the cloaca is not evident until sexual maturity; it was never found in second-year birds, but was open in some third-year birds in a captive flock. Measurements of the bursa of Fabricius indicated much variability in the rate of its resorption in Canada geese. Resorption was incomplete during the first and frequently the second year. Geese with no bursa were 3 yr. or more old; those with a bursa less than 15 mm. in depth were 2 to 3 yr. old; and those with a bursa more than 15

mm. deep may be in the first, second, or third (?) year of life. There are 56 references.

**Bobwhite quail reproduction in southwestern Texas, V. W. LEHMANN.** (Tex. A. and M. Col. et al.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2 pp. 111-123, illus. 1).—Studies of 194 bobwhite nests in a Texas refuge (1942-43) revealed that breeding extended from late March through September, pairing occurring principally among members of the same coveys and laying sometimes beginning before the covey bonds were broken. Breeding activity was staggered, and reneesting was influenced importantly by rainfall. Mesquite semiprairie furnished the most popular breeding range, and bluestem, joint grass, and needlegrass were favorite nesting covers. Quail evidently preferred to nest in grass about 8 in. tall and containing considerable green material. Nest bowls averaged about 4 in. in diameter at the top and 2.5 in. in depth. The average size of the egg clutch decreased as the season advanced, in the spring of 1943 averaging 14.8 eggs but in late summer 10.5. Hatchability was high in spring, decreasing as the weather warmed. Predation by coyotes, skunks, snakes, and fire ants is discussed. Flexible range can accommodate more coveys in certain years than in others, but "good" years produce few new territories in static range. Fall and winter populations are therefore poor barometers of breeding success on static ranges unless the latter are decidedly underpopulated. Important factors regulating quail reproduction in this Texas area are rainfall and coyote predation. Quail are limited by overgrazing, however, on many ranches, and extensive coyote control on such areas would hardly be justified for quail increase.

**Mobility of bobwhite quail in southwestern Texas, V. W. LEHMANN.** (Tex. A. and M. Col. et al.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 124-126, illus. 4).—The bobwhite population of a 560-acre Texas area was found to have moved about much more than indicated by published observations in other regions; some individuals and coveys were relatively sedentary, but the population as a whole underwent continuous movement. Individual birds in winter ranged over strips slightly more than one-fourth of a mile long, but the increase in width of range was small. Range expansion was sometimes gradual, but certain birds leap-frogged from one territory to another. Most quail, it appeared, are acquainted with territories about one-half mile long at 16 mo. of age. Many coveys disappeared from the study area in winter and others disintegrated. Movement during particular periods and fluctuations in densities appeared largely independent of habitat conditions. Ten winter ranges averaged about 643 by 178 yd. All covey ranges overlapped; intraspecific intolerance to crowding appeared unimportant except in competition for choice resting or "headquarters" cover at midday. Covey ranges apparently did not shrink or expand as populations increased or decreased.

**Winter food of bobwhite quail in Virginia, W. P. BALDWIN, JR., and C. O. HANDLEY.** (Va. A. and M. Col. et al.). (*Jour. Wildlife Mgmt.*, 10 (1946), No. 2, pp. 142-149, illus. 1).—Examination of the crops of 495 bobwhite quail collected throughout Virginia during November 15-January 31 revealed that the total food comprised 98 percent plant and 2 percent animal matter. Marked variations occurred in the volume consumed from month to month and section to section for certain species and groups of food items. The native legumes were most important, followed in order by common ragweed, cultivated legumes, cultivated grains, mast, miscellaneous seeds, fruits, animal matter, forage, and native grasses. Native and crop legumes together made over 40 percent of the total winter food. Over 25 percent of the diet was from cultivated crops of all kinds, and a large proportion resulted from agricultural

practices that encouraged the growth of ragweed and common lespedeza throughout the countryside.

**Mechanical value of grit for bobwhite quail**, R. B. NESTLER (*Jour. Wildlife Managt.*, 10 (1946), No. 2, pp. 137-142, illus. 1).—This investigation of 1,372 pen-raised birds in a Maryland refuge revealed that grit as a grinding agent is unessential for their growth, welfare, or reproduction. Seeds such as wheat, millet, milo, soybean, field pea, and vetch were successfully macerated and digested without its aid. When very hard seeds are ingested in the wild, they themselves apparently serve as grinding agents.

**The relation between number of ears opened and the amount of grain taken by redwings in cornfields**, D. W. HAYNE (Mich. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 12 (1946), No. 8, pp. 289-295, illus. 1).—Damage to corn by flocks of the eastern redwing (*Agelaius phoeniceus phoeniceus*) is said to occur locally over a large part of the United States. The feeding by a single bird is small, but on each of a large number of ears; thus the total injury in any one field is the sum of a large number of small amounts of grain eaten during several weeks while the kernels are ripening. The relation between the proportion of ears opened in a field ( $x$ ) by the birds and the proportion of grain removed ( $y$ ) is,  $y = -2.30b \log(1 - x)$ , where  $b$  is the fraction of corn in an ear taken per bird, per visit. The field records given consist of 198 estimates of damage in fields during the 1941-42 seasons; these are classified into 63 groups fitted to the above curve, using logarithms and the method of least squares as ordinarily applied to fitting a straight line. The equation thus derived is,  $y = -0.0062 - 0.2745 \log(1 - x)$ . There is thus a definite relation between the proportion of ears opened and that of grain taken, though this relation is not linear. The larger the number of ears opened, the higher is the loss in grain.

**Blood parasites of the magpie and English sparrow of eastern Washington**, E. D. WAGNER (*Bird-Banding*, 17 (1946), No. 2, pp. 72-74).—Studies of 52 magpies and 25 English sparrows revealed *Haemoproteus picae*, *Leucocytozoon berestneffi*, *Trypanosoma avium*, and microfilaria in the magpies, but only microfilaria in the sparrows.

**A combination photoelectric light meter and fish-detector**, A. D. HASLER and L. V. WHITNEY. (Univ. Wis. et al.). (*Jour. Wildlife Managt.*, 10 (1946), No. 2, pp. 175-177, illus. 2).—The ichthyometer described and illustrated is reported to have been used successfully to chart migration times of perch in Lake Mendota, Wis. Initial results indicated that the detector differentiates between small, medium, and large schools of perch, and therefore has a variety of applications such as observing activity and movements at night, at depths beyond the range of vision, in turbid waters, and in winter under the ice.

**Lethal alkalinity for trout in waters of low salt content**, G. J. EICHER, JR. (*Jour. Wildlife Managt.*, 10 (1946), No. 2, pp. 82-85).—Alkalinity was found a highly lethal factor for trout in Arizona waters low in buffering agents; the symptoms induced are described. Alkaline conditions result from removal of  $\text{CO}_2$  by aquatic vegetation through photosynthesis, resulting in the break-down of bicarbonates into carbonates. Increasing the turbidity lowers the pH by cutting off the light reaching the plants, with consequent lowering of the photosynthetic rate. Introducing fish into streams during periods of turbidity permits them to gain tolerance by the time the pH again rises. Trout were killed under certain conditions at pH 8.8, whereas under others they survived at pH 10.2. This situation may possibly be overcome by

changing the water conditions, by tempering the fish before planting, or by developing species or strains of fish tolerant to such high alkalinity.

**Water temperature and spring fishing, Norris Reservoir, Tennessee, J. S. DENDY** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 89-93, illus. 2).—The best fishing in this reservoir is said to be in early spring and at that time the bass taken are of large average size. The knowledge that temperature greatly influences fish movement in early spring and that at this time the waters are much warmer upstream than in the lower reaches of the reservoir may be of considerable value to anglers. Angling for bass will be best in waters where the temperature is about 60° F. or above, and therefore will tend to be in shallow waters in quiet bays; it may be expected to be best on warm sunshiny days and in midafternoon. In early spring a cold spell may be expected to affect fishing adversely. It is suggested that a pocket thermometer may be of considerable help. If artificial lures are used in water with a temperature above 60°, the angler will have an acceptable explanation for taking few if any fish. Since weather, wave action, temperature of inflowing water, and other factors may all influence the fishing, early spring angling is highly unpredictable because the temperature of the water cannot be anticipated.

**Depth distribution of fish in lower Wheeler Reservoir, Alabama, P. BRYAN and H. H. HOWELL** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 4-9).—"The netting study, though not intensive enough to provide conclusive evidence, suggests that game fish may not be abundant in lower Wheeler Reservoir; that the scarcity of game fish here, as compared to a storage reservoir (Norris), may not be due to the numbers of rough fish present; and that there is a tendency, still unexplained, for fish to avoid the bottom."

**Further studies of depth distribution of fish, Norris Reservoir, Tennessee, J. S. DENDY** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 94-104, illus. 4).—Earlier findings (1943) have already been reported (*E. S. R.*, 93, p. 598); information obtained the second year of the investigation and a comparison of distribution for the two years are here presented. Data from the 1944 netting studies agreed closely with those for 1943 as to the effects of depth, temperature, and bottom on fish distribution, though the water failed to warm quite as rapidly in the second year. As a whole, the 1944 fish population tended to be in slightly cooler and shallower water. In both seasons, fish were caught in water containing too little oxygen to support them over extended periods. In normal years a close enough correlation exists between temperature and fish distribution to permit prediction of summer distribution by making temperature determinations and by noting the distribution for comparable temperature conditions in 1943 and 1944. Since most of the sauger and walleye crop is currently unused, even with year-round fishing, the depth information may improve the harvesting of the crop and, what is equally important, may reduce the number of "un-successful" summer fishing trips.

**Spring fishing on several TVA storage reservoirs, 1945, R. W. ESCHMEYER, D. E. MANGES, and O. F. HASLBAUER** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 78-88).—In 1945—the second season of year-round fishing on Norris Reservoir—a creel census and fisherman count were carried out during April-June; a census was also taken on three other TVA storage reservoirs. The total catch during the second year on Norris Reservoir undoubtedly exceeded that in 1944. A decided difference was noted in the composition of the catch. Crappie were far better represented in 1945; this is attributed partly to a trend toward increased numbers in the reservoir and partly to the very early

warming of the water. Though many bass were taken in March, the number per fishing trip during the census period was considerably below that taken during the same 3-mo. period in 1944. In early 1945—as in the spring of 1944—there was a heavy mortality of large bass, suggesting that the large catch in the spring of 1944 was not excessive and that it represented only a small portion of the adult bass population. For the same period creel census data indicated that even though Norris had yielded almost 275,000 lb. of fish in early 1944 while the other three reservoirs under study were closed to fishing, the average Norris catch was exceeded in 1945 by only one of the other three. Although several more years of census taking are necessary before the trend in fishing can be fully determined, there is as yet no reason to believe that year-round fishing results in an excessive catch.

**Food of several species of fish, Norris Reservoir, Tennessee, J. S. DENDY** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 105–127, illus. 5).—This inquiry included examination of the stomach contents of largemouth bass, smallmouth bass, spotted bass, walleye, sauger, drum, black crappie, channel catfish, and shad; most of them were caught in gill nets during depth distribution studies, 1943–44. Feeding records from natural bodies of water are compared with those from “reservoir” situations. Crawfish, though an important food in natural waters, were virtually absent in Norris; aquatic insects were also scarce. Small shad were the most important food for game fish in this reservoir; black crappie ranked second, and bluegill, skipjack, and miscellaneous items were of less importance. The most important chain was plankton to shad to game fish; the food chain in Norris was short because of lack of aquatic vegetation and the associated biota along the margin of the reservoir. Seasonal differences in the utilization of shad, black crappie, and bluegill by largemouth bass, walleye, and sauger were found to be closely similar. Competition for food among adults of the different fish species is not believed serious because of ample supplies of food and differences in depth distribution. The young shad are available through a great range of depths. There are about 2.5 pages of references.

**Utilization of the sauger crop in Norris Reservoir, Tennessee, R. W. ESCHMEYER and O. F. HASLBAUER** (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 72–75).—Investigations on Norris Reservoir of the Tennessee Valley Authority demonstrate that the crop of this fish can be harvested in winter by limited use of gill nets, and that the nets would take but few fish of other species; the findings are presented briefly.

**Studies on Iowa spiders, K. A. STILES and D. H. LUBER** (*Iowa Acad. Sci. Proc.*, 51 (1944), pp. 473–484, illus. 7).—The authors believe that this report includes many of the more common species of the State and therefore should be of special aid to high school teachers and pupils. The families as well as the species are briefly described.

**An annotated list of the spiders of Maryland, M. H. MUMA** (*Maryland Sta. Bul. A38* (1945), pp. 65+, illus. 15).—This report lists over 400 species of spiders from the State. A foreword is by W. B. Kemp.

**Feeding chemicals to plants and animals for pest control, R. C. ROARK** (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 35–38).—A brief critical review (12 references) of studies of internal medication of animals against parasites and injections of chemicals into plants against insects and fungi, summarizing some of the unsuccessful earlier work and the promise of success from more recent investigations. The “findings open up a field of research that has scarcely been touched during the past 20 yr. and which promises to yield results of great value.”

Factors influencing the interaction of insecticidal mists and flying insects. —II, The production and behaviour of kerosene base insecticidal spray mists and their relation to flying insects, W. A. L. DAVID (*Bul. Ent. Res.*, 37 (1946), No. 1, pp. 1-28, illus. 1).—In this contribution (*E. S. R.*, 95, p. 356) a theoretical discussion and review (17 references) is followed by an account of the experimental work, the aim being—through the methods and apparatus described—to obtain a reasonably comprehensive picture of a unit of the atmosphere to which the flying insect is exposed. The size of the particle in mist—once it has left the spray gun—is largely determined by its ability to evaporate, as expressed chiefly by its size, vapor pressure, and the quantity of vapor already present in the surrounding atmosphere. The evaporation rate of the droplets is greatly depressed even when the atmosphere is very far from being saturated. If the spray contains materials of low vapor pressure the percentage of these present determines the ultimate particle size. The effect of changing the spraying pressure on the particle size in the mist is largely masked by precipitation and evaporation. The difference in particle size in the mist obtained with odorless kerosene and white oil (P 31) when sprayed through the same gun at the same pressure is largely an expression of the greater rate of evaporation of the former. The more quickly the carrier evaporates the smaller the particle recovered and the greater the quantity of any nonvolatile material present in the original spray remaining in suspension in the air space.

When nonvolatile material is present in the spray this—by failing to evaporate—determines the ultimate particle size in the mist. When the volume of a volatile spray injected into the chamber is increased, evaporation of the droplets is depressed so that they persist longer at a greater size level and so deposit more easily and are more readily impacted. The number of particles per unit volume of air space decreases with time, and a much greater number remains at a countable size when an appreciable quantity of nonvolatile material is incorporated in the spray. Wherever the attempt has been made, it has proved possible to show that a decrease in the quantity of spray mist in suspension in the atmosphere and a decrease in particle size in the mist as measured by the sampling devices used are attended by corresponding reductions in the insecticidal efficiency of the mist as measured on the yellow fever mosquito. In assessing the insecticidal efficiency of a mist it is not sufficient to know the quantity of insecticide in suspension in the atmosphere; the particle-size distribution must also be known. It is emphasized that the biological tests reported were all carried out on the yellow fever mosquito, and that the results may not be applicable to other insects without modifications.

Azobenzene as an acaricide and insecticide, R. C. HARING (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 73-80).—Commercial parasitocides using azobenzene as the active ingredient have been developed; these, like other parasitocides, are specific in action. Use of dusts containing 20 percent of azobenzene in whiting or bentonite resulted in the complete control of several species of economically important pests. These dusts are particularly effective against red spider mites and the Mexican bean beetle, which have hitherto been difficult to control.

The new insecticides D. D. T. and benzene hexachloride and their significance in agriculture, H. SHAW (*Jour. Roy. Agr. Soc. England*, 106 (1945), pp. 204-220).—The author presents a review (66 references) of the history and present status of DDT and 666, with the conclusion that much remains to be done in the way of devising the most suitable combinations for par-

ticular purposes, determining the minimum concentrations for effective control, and observing their cumulative effects on the general fauna of treated areas. These materials have opened up entirely new possibilities in insect control, but have at the same time brought in potential dangers. It is thus essential that the first few years of their commercial use should be regarded as an extension of the experimental phase and entered into with a willingness to accept and act on the findings of careful and reliable observations. "There is little doubt that if such a rational outlook is maintained toward the development of these materials, they are capable of facilitating perhaps the greatest single step forward that man has ever made in his unending contest against the insect world."

**Studies on the toxicity of DDT for domestic and laboratory animals.** H. KONST and P. J. G. PLUMMER (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 5, pp. 128-136, illus. 1).—Toxicological studies of commercially pure DDT indicated its acute toxicity to large domestic animals to be lower than for laboratory animals. In the laboratory species tested, higher toxic levels were obtained after oral administration than after subcutaneous injection; oil solutions proved more toxic than aqueous suspensions. Variations in species susceptibility were usually well marked; individual variations remained within limits which permitted the grouping according to drug susceptibility. Of the animals tested, rats exhibited the highest susceptibility; guinea pigs and swine, the greatest resistance. Mice, rabbits and chickens, cattle, goats, and sheep occupied intermediate positions, their resistance increasing in the approximate order given. No symptoms were induced by feeding DDT-dusted cabbage leaves and sprayed apple parings to rabbits, guinea pigs, and rats, or by feeding flies knocked down by a DDT spray to chickens. Gross pathological changes after single large doses occurred mainly in the liver; in the chronic toxicity tests there were no changes. The histological findings were similar in the acute and chronic toxicity tests, the difference being only in the degree of severity; the principal lesion was a degeneration of the liver.

**The present status of D. D. T. as an insecticide.** G. A. H. HELSON and D. F. WATERHOUSE (*Jour. Austral. Inst. Agr. Sci.*, 11 (1945), No. 4, pp. 172-178).—This summary of present knowledge on DDT is discussed under the forms in which it may be used, methods of application, and toxicity to insects, higher animals, and plants.

**DDT residual-type sprays as affected by light.** A. W. LINDQUIST, H. A. JONES, and A. H. MADSEN. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 55-59).—Boards, petri dishes, and glass plates sprayed with DDT solutions, emulsions, and suspensions were exposed to ultraviolet light and to sunlight, duplicate treatments being unexposed as checks. In the DDT solutions 15 percent of various auxiliary solvents were included. Exposure to either type reduced the effectiveness in most cases, as shown by the time required for knock-down of houseflies. With several high-boiling auxiliary solvents, however, this reduction was particularly severe. It appears from the findings that in general, where decomposition by light may be a factor, auxiliary solvents used in conjunction with kerosene in DDT residual sprays should not only be good solvents for DDT but should be of the boiling range of kerosene or lower. Solvents of very low flash point should be avoided. Xylene emulsions and aqueous suspensions were less affected by light than solutions.

**Correlation between the possession of a chitinous cuticle and sensitivity to DDT.** A. G. RICHARDS and L. K. CUTKOMP. (Minn. Expt. Sta. et al.).

(*Biol. Bul.*, 90 (1946), No. 2, pp. 97-108).—A correlation is said to exist among animals between the presence of a chitinous cuticle and susceptibility to external applications of DDT. Aquatic animals with such a cuticle (arthropods and certain coelenterates) are highly susceptible; others are less so, though there is considerable variability. This correlation is supported by studies on various coelenterates on adsorption, and on temperature coefficients. Coelenterata with a complete, partial, and no chitinous perisarc, respectively, are highly sensitive, somewhat so, and nearly insensitive to DDT, which can be adsorbed by chitin and chitinous cuticles and at low concentrations has a negative temperature coefficient for toxicity to arthropods. From such findings the hypothesis is proposed that chitinous cuticles facilitate the entry of DDT into the animal body by selectively concentrating the compound by adsorption phenomena. This is believed to be the first demonstration that an insecticide can be adsorbed by chitinous cuticles and the first direct evidence that such adsorption actually plays a role in insecticidal action. The nature of the toxicity of DDT to protoplasm is not here considered, the data presented referring only to the selective action of DDT as a function of penetration facilitated by chitinous exoskeletons. The shift to a positive temperature coefficient at higher concentrations, the lack of effect from injecting DDT emulsions into snails, and the variability in median lethal doses for injected DDT emulsions in different animals all indicate that the selective adsorption of DDT by chitinous cuticles is only part of the story of the toxic action of this compound.

**DDT and its effect on fish and wildlife**, C. COTTAM (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 44-52).—Observations of the effects on wildlife of DDT used for insect control were made in 12 States and the Province of Ontario; fair to successful insect control was obtained. The principal investigations were on forest lands in Maryland and Pennsylvania. Applications were made chiefly by airplane as an oil spray, concentrations being 0.2 to 5 lb. per acre; the greatest amount used anywhere was 25 lb. per acre as a dust. The amount of DDT actually reaching the vegetation varied considerably from the specified rate of application owing to bad weather, lack of landmarks, defective apparatus, and differing density of vegetation. The mortality in wildlife was pronounced from use of most of the higher, but was slight or inapparent from most of the lower, concentrations. Invertebrates and cold-blooded vertebrates were more readily affected than birds and mammals. In the single trial involved, DDT was far more toxic in emulsion than when applied in oil or as a suspension. Recommendations on the basis of the findings are: Don't use DDT unless you must, always use minimum necessary dosages, apply carefully, leave a sanctuary time the application, avoid spraying water, and watch what happens. These are each discussed briefly.

**Investigation on the locus of action of DDT in flies (*Drosophila*)**, D. BODENSTEIN (*Biol. Bul.*, 90 (1946), No. 2, pp. 148-157, *illus.* 3).—Larvae and adults of *D. virilis* were fatally poisoned by injecting a 1-percent DDT emulsion into the abdominal cavity; this produced a typical symptom pattern. The neuromuscular system of the wings and legs appeared very sensitive to DDT, going into spasm long before the muscles of the abdominal wall. There was also a difference in sensitivity between larvae and adults, the former proving more resistant. Phenobarbital was also found to affect the nervous system; paralysis was induced in the absence of the central ganglia, showing that this drug likewise affects the peripheral nerves. The muscles of larvae treated with phenobarbital respond to mechanical stimulation. Since DDT produced no symptoms in individuals treated with phenobarbital

and those treated with DDT lost their DDT symptoms when injected with phenobarbital, it is clear that DDT acts on the nervous system. Moreover, body parts isolated from the central nervous system and then treated with DDT stopped convulsing after phenobarbital administration, indicating that DDT affects the peripheral nerves. Though the methods used did not allow determination of what part of the peripheral nervous system might be affected, three possibilities are suggested, viz, the poison might affect (1) the motor nerves leading to the periphery, (2) the myoneural junctions, or (3) the peripheral nerve net. It is believed still questionable, however, whether such a nerve net exists in *Drosophila*. The antagonistic effect of phenobarbital was clearly shown by the fact that the spasm of the legs and wings in DDT-treated flies was partly relieved by phenobarbital treatment. The conception that only the nervous system is affected by DDT is strengthened by the fact that larval organs (imaginal disks) exposed to DDT for 20 hr. grew and differentiated normally when transplanted into untreated larvae.

**Protection of plants from black beetle by DDT applied to the soil, C. R. WALLACE** (*Journ. Austral. Inst. Agr. Sci.*, 11 (1945), No. 3, pp. 135-139, illus. 1).—It is clear that the DDT treatments on marigolds and during the first 3.5 weeks after setting out cauliflower plants will enable the grower to secure sound crops in the face of severe attacks by the dynastid beetle *Heteronychus sanctae-helenae* Blanch. Its range of host plants is, however, extremely wide and there are indications that at least one of these hosts (tomato) might react adversely to certain dosages of DDT in the soil. As to the last factor, much more needs to be known on the rate of break-down of DDT under soil conditions.

**DDT knocks insects that plague farmstead, R. H. DAGGY** (*Minn. Farm and Home Sci.* [Minnesota Sta.], 3 (1946), No. 3, pp. 6-7, 10-11, illus. 2).—An evaluation of the uses of DDT for farm and home on the basis of present knowledge of this insecticide.

**Toxicity of D. D. T. to man, F. M. G. STAMMERS and F. G. SAREL WHITFIELD** (*Nature*) [London], 157 (1946), No. 3994, p. 653).—The clinical and special investigations and general demeanor and labor output of men engaged in spraying ships and shore establishments against mosquitoes indicated that no ill effects had been incurred from prolonged exposure of the skin to the DDT solution and from working in confined spaces in a mist of the spray.

[DDT and lead arsenate-phenothiazine sprays] (*Pennsylvania Sta. Bul.* 475 (1946), Sup. 1, pp. 1-6+, illus. 2).—The following brief articles are included: DDT Not a New Chemical—New Only as Insecticide, by D. E. H. Frear (pp. 1+); Insect Control Demonstrations with DDT in Pennsylvania, by J. O. Pepper (pp. 1-2); DDT Controls Codling Moth, Allows Mites to Increase, by H. M. Steiner (pp. 2-3); DDT Effectively Controls Grape Insects in 1944-45, by J. A. Cox (pp. 3-4); DDT in Combination Sprays Increases Yields of Potatoes, by H. W. Thurston, Jr. (p. 4); DDT Less Harmful to Bees Than Apiarists Have Feared, by E. J. Anderson (p. 4); and Lead Arsenate-Phenothiazine Spray Helps Prevent Codling Moth Outbreak, by H. M. Steiner (pp. 5-6).

**A study of stickers for lead arsenate sprays on fruit trees, P. GARMAN** (*Connecticut* [New Haven] Sta. Bul. 485 (1945), pp. 105-161, illus. 21).—Laboratory and orchard experiments led to the following conclusions: Lead arsenate alone sticks better than lead arsenate plus dry flotation sulfur or plus flotation sulfur and lime. Lead arsenate plus lime shows improved adhesion over lead arsenate alone on glass slides but not on foliage—espe-

cially at high concentrations. Oils are good deposit builders; they are also good stickers, but the amounts used should be in proportion to the amount of solids in the spray mixture. Bentonite plus 20 percent skim milk or casein is an excellent sticker, second only to the oils; in the dry 1944 season, it equalled the oils in field experiments. Aluminum gel is also a good sticker, and various compounds utilized in these experiments evidently produce some form of aluminum gel. Aluminum gels, including bentonite, acts as safeners for both oil and lead arsenate, thereby preventing foliage burn even though the arsenic is retained on the leaves in large amounts over a long period of time. By utilizing stickers that are good deposit builders and safeners as well, the total number of sprays needed may be reduced considerably in seasons such as 1943 and 1944.

The advantages of the reduced schedules in Connecticut appear to lie in improved control of European red mite and apple maggot, as well as reductions in spray russet, foliage burn, and drop. There are also savings in labor, gasoline, and depreciation of machinery. The main objections lie in the difficulty of handling the complex mixtures and the rather poor control of curculio in bad years. Supplementary treatments may be needed in certain seasons, but these should not detract from the value of the method. Curculio control in 1944 was as good as or better than that obtained with the standard spray schedule. Although no difficulty in controlling codling moth has followed use of the reduced programs and increased dosages of lead arsenate, the method is not yet recommended when codling moth becomes a threatening factor in Connecticut fruit production. It is believed that reduced programs, such as those described, may have a definite place in the State for such varieties as Baldwin, Wagner, Stayman, or similar varieties. The method has not been tested sufficiently in wet years to warrant present recommendation for scab-susceptible varieties.

Involvements in research in present day economic entomology, D. L. VAN DINE (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 1-5).—Presidential address, fifty-seventh annual meeting, American Association of Economic Entomologists.

Entomological nomenclature and literature, W. J. CHAMBERLIN (*Ann Arbor, Mich.: Edwards Bros., 1946, 2 ed., pp. 135+, illus. 2*).—In this edition, a third part on preparing articles for scientific publication has been added (E. S. R., 86, p. 806).

Catalogo de los insectos que atacan a las plantas economicas de Cuba [Catalog of the insect and other arthropod pests of crop plants in Cuba], S. C. BRUNER, L. C. SCARAMUZZA, and A. R. OTERO (*Habana: Cuba Estac. Expt. Agron., 1945, pp. 264+, illus. 76*).

Influence of soil minerals on insects, L. HASEMAN. (Univ. Mo.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 8-11).—These investigations—begun some years ago and thus far largely of an exploratory nature—have included the green bug, chinch bug, greenhouse thrips, greenhouse white fly, and Colorado potato beetle. In general, it was the plants grown on the lower N levels that were most attractive to these pests. As with the higher animals, for optimum development and reproduction each insect appears to have its specific nutritional requirements which, according to these findings, would seem to vary greatly as far as minerals are concerned from those of man and other vertebrates. The indications are that insects require less of minerals and that they actually thrive best on shortages of certain ones. It is believed probable that different crop pests will vary as to which minerals they require in reduced quantities; it would seem, however, that by lowering the total level

of soil minerals through erosion, overcropping, and faulty rotations, conditions are being systematically improved for insect pests while at the same time they are becoming less and less favorable for crops, livestock, and man. Soil improvement, as well as insecticides, would seem to be indicated.

[Notes on insects and insecticides] (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 81-94).—Contributions presented (W. S. R., 95, p. 77) are Benzene Hexachloride to Control Bugs on Cotton, by W. A. Stevenson and L. W. Sheets (p. 81) (U. S. D. A.); Mosquito Collections at Army Installations in the Fourth Service Command, 1918, by S. J. Carpenter and R. W. Chamberlain (pp. 82-88); The Control of the Blueberry Bud Mite [*Eriophyes vaccinii* K.], by J. S. Bailey and A. I. Bourne (p. 89) (Mass. Expt. Sta.); Collections of Mosquitoes on Parris Island During 1945, by G. H. Bick (pp. 89-91); DDT and Hairyfly Populations, by L. M. Peairs (pp. 91-92) (W. Va. The economic importance of dragonflies (Odonata), M. WRIGHT (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 69-71).—On the basis of the literature (29 references) and on independent studies, the author discusses both the beneficial and harmful aspects of dragonflies. These insects are taken as food by many species of fish, but constitute a major dietary item only in certain species, such as trout and bass, which are animal feeders. The nymphs constitute an important part of the diet of ducks and other birds feeding in aquatic areas on animal rather than plant food. Flies, mosquitoes, and gnats are eaten by practically all species of Odonata, and especially when these pests occur in large populations. The available information indicates that although large numbers of the pest insects are destroyed by dragonflies, little or no effective control is effected. Two dragonflies—*Anax junius* and *Coryphaeschna ingens*—have been shown to be destructive to both queen and worker bees in the Southeastern States. Nymphs of certain of the larger dragonflies capture and eat small fish; when these species are present in large numbers, particularly in hatchery ponds, considerable destruction of fish occurs, often resulting in 50 percent or greater losses in population. It is emphasized that the greater number of dragonfly species are not thus involved, but are themselves fed upon by larger fish. The nymphs and adults serve as intermediate hosts for a considerable list of flukes, and probably will be shown to be important vectors of many such parasites of aquatic vertebrates that feed on members of the dragonfly group.

Diapause in *Scelio chortioctes* Frogg. (Scelionidae), a parasite of the eggs of *Austroicetes cruciata* Sauss., L. C. BIRCH (*Jour. Austral. Inst. Agr. Sci.*, 11 (1945), No. 4, pp. 189-190).—A note on this parasite of Australian plague grasshopper eggs.

The use of transport and poison bait in a locust campaign, R. J. M. SWYNNERTON (*East African Agr. Jour.*, 11 (1946), No. 4, pp. 224-230).—The author presents notes compiled as a result of a locust control campaign in Tanganyika (1944) in which the "hoppers" were already hatched before it was possible to organize the assembly of equipment. It was believed that the information obtained might be of use to others having the responsibility of organizing similar campaigns at short notice. Summaries are given of the plan of campaign, equipment, behavior of the hoppers, supply and preparation of poison bait, baiting organization, methods and rates of baiting, observations of results, arsenical poisoning, and mechanical methods of hopper destruction.

A list of the Chloropidae (Diptera) known to occur in Iowa, L. REDLINGER and H. E. JAKES (*Iowa Acad. Sci. Proc.*, 51 (1944), pp. 471-472, illus. 1).—The chief purpose of this brief paper is to list the known Iowa species of these frit flies.

The Nearctic species of *Iteaphila* and *Apalocnemis*, A. L. MELANDER. (Univ. Calif.). (*Bul. Brooklyn Ent. Soc.*, 41 (1946), No. 2, pp. 29-40, illus. 8).—In these two dipterous genera, six new species are described for *Iteaphila* and two for *Apalocnemis*, with keys for identification.

Light-trap studies of the Clear Lake gnat, A. W. LINDQUIST and C. C. DEONIER. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 11-14, illus. 2).—In studies of the relative attractiveness of lights of various intensities and wavelengths to the Clear Lake gnat, it was found that with filament lamps the numbers taken per unit of light decreased inversely with the intensity. A 500-w. lamp took only a little over 2.3 times as many as a 100-w. lamp. A double-action trap, in which one 150-w. lamp was placed over the motor and another below, captured nearly twice as many gnats as a single-action trap fitted with a 300-w. lamp suspended above the motor. A 15-w. daylight fluorescent lamp attracted 2.33 times as many as a 60-w. filament lamp and took over 6 times as many gnats per watt. Trials with larger fluorescent lamps and regular filament lamps indicated that—on an equal lumen-rating basis—the former captured more gnats than the latter and up to 7.33 times as many per watt. Daylight and blue fluorescent lamps attracted about the same number of gnats, but on the basis of numbers captured per lumen the blue lamp was considerably better. Daylight fluorescent lamps were more efficient than the white, pink, green, or red.

Life histories and ecology of Iowa midges (Tendipedidae).—I, The genus *Tanytarsus*, U. A. HAUBER (*Iowa Acad. Sci. Proc.*, 51 (1944), pp. 451-461, illus. 30).—Some 11 entities are described and assigned to this genus; "the group has had little attention in this country and there are few types available for comparison. Under the circumstances any attempt to classify specimens is done subject to future corrections."

Check list of the Cicadellidae (Homoptera) of America, north of Mexico, D. M. DELONG and D. J. KNULL (*Columbus: Ohio State Univ. Press*, 1945, pp. 102+).—In addition to the annotated check list of the leafhopper family, a key list of publications, suggested generic papers on North American Cicadellidae, and an index to the genera are included.

A new genus (*Costamia*) and species of Mexican leafhopper (Homoptera: Cicadellidae), D. M. DELONG. (Ohio State Univ.). (*Ann. Ent. Soc. Amer.*, 39 (1946), No. 1, pp. 82-83, illus. 3).—*C. venosa* n. gen. and sp. are described and illustrated.

A preliminary report on the Geometridae of Iowa, E. JERREL and H. E. JAKES (*Iowa Acad. Sci. Proc.*, 51 (1944), pp. 463-465, illus. 2).—A listing of the geometrid moths reported from the State.

Undescribed species of *Tipula* from western North America (Diptera: Tipulidae), II, C. P. ALEXANDER. (Mass. State Col.). (*Bul. Brooklyn Ent. Soc.*, 41 (1946), No. 2, pp. 45-51).—Three more new species (E. S. R., 93, p. 602) are described.

Descriptions of new genera and species of Mymaridae (Hymenoptera: Chalcidoidea), A. A. OGLOBLIN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 20 (1946), No. 3, pp. 277-295, illus. 19).—The following six new chalcid fly genera, with species thereunder, are described: *Chaetomyrmar*, *Tetrapolynema*, *Barypolynema*, *Acmopolynema*, *Platystethynium*, and *Platypatasson*. A new species of *Lymaenon* is also included.

**Insect pollinators of alfalfa in California, E. G. LINSLEY.** (Univ. Calif.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 18-29).—From the information obtained in surveys of alfalfa seed fields in four California areas (1945), the following conclusions are drawn: The only significant insect pollinators of alfalfa appear to be bees; no other insects were observed to trip the flowers deliberately, although a species of wasp tripped and cross-pollinated mechanically in the Palo Verde Valley. In each of the areas concerned in this study, the major portion of the tripping and pollination was done by wild bees; in the Palo Verde Valley 12 species were thus observed, and among them *Nomia peninsularis* Ckll. was the most abundant, being found in every field. In the Hemet Valley, 19 species were found; among them, *Melissodes timberlakei* Ckll., various species of *Megachile*, *N. melanderi* Ckll., and *Anthidium edwardsii* (Cress.) were probably the most important, but no single species was found in every field. In the northwestern part of the San Joaquin Valley, 14 species were encountered; among them *Melissodes timberlakei* appeared by far the most important, followed closely by *Megachile brevis* Say, *M. onobrychidis* Ckll., and *A. edwardsii*. In the delta area of the Sacramento Valley, 13 pollinators were found; of these, *Melissodes timberlakei* and *Megachile* spp. were again the most important. Honeybees were present in varying numbers in all the fields, but both the percentage and total numbers of pollen collectors compared unfavorably with the solitary bees. Bumblebees, though individually more efficient than honeybees, were usually not abundant enough to be regarded as important for alfalfa pollination.

**A report on the status and control of insect pests of cotton in the Lower River districts of Nyasaland, E. O. PEARSON and B. L. MITCHELL** (*Zomba: [Dept. Agr. Nyasaland], 1945, pp. 48+, illus. 7*).—"This report deals with the causes of the great fluctuations in production of cotton in the area of Nyasaland known as the Lower River, and is the result of work carried out by the entomological staff of the Empire Cotton Growing Corporation in this country since 1938."

**Benzene hexachloride to control cotton insects, E. E. IVY and K. P. EWING.** (U. S. D. A. coop. Tex. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 38-41, illus. 1).—In laboratory and cage tests at Waco, Tex., benzene hexachloride dust gave excellent results with several important cotton insects. Control of the boll weevil and cotton leafworm was better than with calcium arsenate. Its effectiveness against the cotton flea hopper, tarnished plant bug, and southern green stinkbug was equal to or better than that of DDT. Better control of the cotton aphid was obtained than with nicotine dusts, but DDT and heavy dosages of calcium arsenate dusts each gave better bollworm control than benzene hexachloride.

**Cooperacion entre los Estados Unidos de Norteamerica y la Republica de Mexico, para el control del gusano rosado del algodono [Cooperation between the United States and the Republic of Mexico on the control of the pink bollworm of cotton], A. DELGADO DE GARAY** (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 95-98).

**Factors involved in the separation of *Macrocentrus ancyliivorus* cocoons from tuber worm pupae, C. H. MARTIN and G. L. FINNEY.** (Univ. Calif.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 29-35).—These studies revealed that, with proper precautions, there is no mortality of the stages of *M. ancyliivorus* Rowher in the cocoons as a result of freeing them from host cocoons and separating them from host pupae. Such precautions include elimination of mechanical factors by sanding the cocooning trays and proper use of a trap-bottomed vessel for freeing and separation of the parasites from the hosts.

Toxicity factors are avoided when only stable solutions of sodium hypochlorite are used for freeing and alcohol with a specific gravity of 0.920 B. is used for separation. Since the parasites must be separated from the host pupae before the latter float, superparasitized host larvae are lost, although the parasites would eventually have emerged from them. Superparasitism can be reduced by exposing the hosts for 3 days. Freeing and separating the parasites is done when the host cocoons are 6 to 7 days old. The date of freeing depends on the time when 75 percent of the parasites have pupated.

**The pickleworm:** Cucurbit enemy No. 1, B. B. FULTON (*Res. and Farming* [North Carolina Sta.], 4 (1946), *Prog. Rpt. 2*, pp. 6-7, 10, illus. 1).—The pickleworm is said to rank first in North Carolina among the insect enemies of the cucumber family. This contribution outlines the life history of the pest and summarizes methods of control through avoidance and dusting as based on work by the station. By early planting the crop may be matured before the arrival of the insect. The best insecticide against it was found to be cryolite—either synthetic or natural; detailed procedures for its use are presented.

**Susceptibility of hibernating codling moth larvae to low temperatures, and the bound-water content,** E. H. SIEGLER. (U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 72 (1946), No. 10, pp. 329-340, illus. 7).—The author investigated the bound-water content of hibernating larvae of the codling moth and their susceptibility to low temperatures as shown by the temperature to which they could be cooled before beginning to freeze. Unlike some insects, the codling moth fails to withstand more than one freezing. The overwintering larvae show pronounced tendency to undercool; the average undercooling temperatures for different groups ranged from  $-24.4^{\circ}$  to  $-30.1^{\circ}$  C.; the average rebound temperatures to which the temperatures of the insects rose after freezing had started ranged from  $-5.0^{\circ}$  to  $-11.2^{\circ}$ . No marked differences in susceptibility to low temperatures—as indicated by undercooling temperatures—were shown by larvae from Washington, Colorado, Arkansas, Maryland, and Georgia. The undercooling temperatures of the larvae were practically unaffected by sex or weight, nor did exposure to artificially created dry and humid conditions indicate any marked changes in this respect. The undercooling temperatures of crossbred larvae were similar to those of their progenitors. Undercooling is favored by the quiescent state during hibernation; artificial movement of the larva greatly reduced the undercooling. The average bound-water content of the larvae was 35.9 percent when determined by the dilatometric method at  $-7.5^{\circ}$  and 11.2 percent by the heat-of-fusion-of-ice method at  $-30^{\circ}$ .

**Notes on the time of emergence, longevity, and oviposition of codling moth from walnuts, apples, and pears,** A. J. BASINGER and H. S. SMITH. (Calif. Citrus Expt. Sta.). (*Calif. Dept. Agr. Bul.*, 35 (1946), No. 1, pp. 37-38).—The codling moth has in recent years become an important pest of Persian walnuts in California, suggesting that a new race may be in process of development. To study this question, larvae were procured from apples and pears in different localities during the fall (1940) and taken to Riverside for emergence. No significant differences occurred in the emergence time of adults from the various localities except in those from the Stockton district, where—though it is 300 miles north of the other areas—emergence was distinctly earlier. Furthermore, in this locality emergence was slower from walnuts than from apples; in the southern part of the State emergence from the two hosts was almost coincident except at the Whittier-Downey district.

where that from walnuts came first. The length of life of moths from the various localities and from the two hosts was fairly close.

An effective method of controlling codling moth in Oklahoma orchards, F. E. WHITEHEAD (Okla. A. and M. Col.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 69-76, illus. 1).—The author suggests that the plan of orchard planting in which all varieties are mature and harvested by August 15 would greatly reduce the codling moth problem in Oklahoma. Pupation and hibernation records of larvae collected from trees grouped according to their date of ripening indicate that only approximately 9 percent of the total hibernating population had entered hibernation by August 15, and that less than 2 percent hibernated on the trees maturing fruit by August 15. The plan is considered inexpensive and practical for Oklahoma conditions, because it costs no more to set out this type of orchard and early apples are more economically produced and normally bring higher prices. The author admits that, with the present information, the proposed plan is based to a considerable extent on theory. Plans are already under way, however, which it is hoped will give more complete information than that now available.

Development of the immature stages of *Anastrepha serpentina* in relation to temperature, J. G. SHAW and D. F. STARR. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 72 (1946), No. 8, pp. 265-276, illus. 6).—Since *A. serpentina* (Wied.) is known to develop in several economically important fruits and has appeared in the lower Rio Grande Valley of Texas as a threat to the citrus industry, a study of the development of the immature stages was undertaken at the Mexico City laboratory. First oviposition occurred 16 days after the flies began to emerge from puparia. Eggs were procured from confined flies by exposing arcs of fruit skins fastened by paraffin to glass plates. The fact that this fruitfly preferred chicozapote skins to peach skins for oviposition proved highly significant. Eggs for incubation and hatching studies were held in Syracuse watch glasses in cabinets at 10° to 37.8°C.; hatching occurred at 15° to 32.5°. The incubation period covered 361 to 645 hr., after which the hatching process approximated a straight line when the probit of the cumulative percentage of hatch was plotted against the logarithm of time. The temperature effect on the reciprocal of the incubation period and on the rate of hatch was measured so that approximate hatching curves might be calculated between 15° and 30°.

The larvae were reared at 15° to 32.5° by placing them in slices of fruit held between glass plates. Mealy-ripe chicozapote provided the better medium for larval development, but peach was also used. Molting of the first instar was observed in some detail. The second stadium was generally shorter than the first, but the third was considerably longer than either of the others. In peach, the larvae developed in 50 to 17.4 days at 15° to 30°; in chicozapote, in only 41.5 to 11.7 days at the same temperature range and in 11 days at 32.5°. The holding and care of puparia in crystallization dishes is described, the developmental time proving nearly the same for those formed from larvae fed on peach and on chicozapote. The development from egg to adult ranged from 121 days for one individual reared in peach at 15° to 26 days for individuals reared in chicozapote at 30° and 32.5°; development in peach was invariably longer, the difference being in the feeding or larval stage. When the rate of development in each fruit—measured by the reciprocal of time in days—was plotted against temperature, linear regression lines were produced.

DDT to control bugs that cause deformed peaches, O. I. SNAPP. (U. S. D. A. coop. Clemson Agr. Col. et al.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 41-48, illus. 1).—Deformed peaches caused by sucking bugs are respon-

sible for a large part of the culls in many South Carolina orchards. The tarnished plant bug was found on peach trees in Spartanburg County orchards from full bloom until petal fall, and available evidence indicates it to be largely responsible for the deformed peaches in that area; other bugs were present in very small numbers only. Preliminary tests showed that jarring cannot be depended on to control these pests, but that DDT might give control; in subsequent large-orchard tests, a single application at full bloom reduced the injured peaches at harvest from 42.4 to as few as 7.8 percent. The results showed little difference in plant bug control from 5 to 10 percent DDT dusts, used at the rate of about 0.2 lb. per tree, or DDT sprays at strengths of 1 or 2 lb. of the technical material per 100 gal. of spray, used at the rate of about 1.5 gal. per tree. There was no difference in the degree of control of sucking bugs from 5 percent DDT dust whether or not the fruit had been thinned.

**Timing spray applications to control the pecan nut casebearer, W. C. PIERCE.** (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 76-78).—It appears from the data presented that there may be sufficient correlation between the blossoming stages on certain varieties and the time when the pecan nut casebearer eggs are deposited and hatch to serve as a basis for determining spray dates for its control. The time at which 85 to 100 percent of the catkins had dropped from the varieties Burkett, Eastern Schley, and Mahan more nearly indicated the time to spray than when certain other varieties developed receptive stigmas. The method of determining the beginning of stigma receptivity is, however, simple and under some conditions it may be desirable to use these observations. Pending further study, it is suggested that the spray applications be timed to begin 4 to 8 days after 85 percent or more of the catkins of these varieties are shed. Observations may be made on the abundance of first-generation eggs in the orchard for determining whether to begin spraying on the fourth or the eighth day. Under Texas conditions the sprays should usually be applied during the second week after the shedding of 85 percent or more of the catkins; approximately 25 trees in different parts of the orchard should be used to determine this time. It is believed possible to substitute other varieties of the protogynous group for those presented here, provided the proper adjustments are made for differences in time of shedding pollen.

**Tolerance of citrus fruits to methyl bromide as a fumigant, H. M. ARMISTAGE and J. B. STEINWEDEN** (*Calif. Dept. Agr. Bul.*, 35 (1946), No. 1, pp. 21-29, *illus.*).—Lemons and California Bearss limes were uninjured by any of the methyl bromide dosages used. Grapefruit were uninjured by minimum dosages at which 100 percent kill of California red scale can be secured with this chemical, but were marked and discolored by higher concentrations. Washington Navel oranges became spotted or discolored at all dosages used—even below the lethal level for the scale. The injury was slow to appear and was manifested by a gradual breaking down of the oil cells and intercellular tissues, resulting in deep pits in the brown areas. California Bearss limes were uninjured by HCN fumigation when applied dry but—due to condensation water—even light schedules injured them when treated directly from a refrigerator. The red scale on citrus fruits was killed 100 percent by methyl bromide at 2.5 lb. per 1,000 cu. ft. at 80° and at 3 lb. per 1,000 cu. ft. at 70° F. Limited tests showed that the scale was killed with dosages of 15 cc., 20 cc., and 25 cc. per 100 cu. ft. for 1 hr., and extensive counts showed 100 percent kill with 25 cc.

DDT to control household and stored grain insects, J. J. DAVIS. (Ind. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 59-61).—In this symposium paper the author presents a brief resumé of published results against stored grain and household insects, including mothproofing.

Tyroglyphid mites in stored products—ecological studies, M. E. SOLOMON (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 82-97, *illus.* 4).—Manitoba grain stored in bulk in one granary was repeatedly examined over 15 mo., and corroborative data were obtained in other granaries. The chief mite pest of grain was *Tyroglyphus farinae* (L.); in imported grain it usually attacks only those parts of a bulk which have taken up extra moisture. *Glycyphagus destructor* (Schr.) is commonly found throughout the surface layer, but does no damage to the grain. Differences were found in the distribution and population density of *Tyroglyphus*, *Glycyphagus*, and the predatory mite *Cheyletus eruditus* Schr. in relation to the moisture content of the grain. *Tyroglyphus* was abundant in winter and spring, but was often reduced to very small numbers during fall and winter because of attacks by *Cheyletus*; the former multiplies less rapidly as the moisture decreases, so that under the drier conditions in stored grain during summer and fall *Cheyletus* is enabled to control it. A subsidiary factor was the migration of *Tyroglyphus* into somewhat drier grain after dense populations had exhausted the wheat germ; extremely high moisture occasionally appeared to cause similar migrations. The seasonal temperature difference may also have been a factor influencing the predator/prey cycle. *Cheyletus* survived in grain too dry for *Tyroglyphus*. The predator was also associated with *Glycyphagus*, but was usually unable to reduce its numbers to a comparable extent; it is also known to attack various insects.

Grain stored in bags has a much larger area exposed to atmospheric moisture; thus infestations tend to be more widespread than in bulk grain. It is important to keep the bags away from concrete floors. *Cheyletus* is less common in bagged grain and in flour. The findings regarding infestations of flour in bags were similar to those for bagged grain. Mites tended to concentrate in the more superficial flour, very few penetrating more than a few centimeters into the flour; this would facilitate fumigation. It appears possible that tyroglyphids—or at least their eggs—may survive the milling process. Dried fruits seemed to have become infested with *Carpoglyphus lactis* (L.) as a result of moisture increases. The most effective means of preventing infestation of stored products by mites is to keep them moderately dry; failing this, steps should be taken to prevent local increases in moisture. It might be useful under certain conditions to introduce *Cheyletus*—perhaps together with *Glycyphagus* as a source of food—into stored products to prevent the possibility of *Tyroglyphus* being introduced without its predators—e. g., after fumigation.

Analysis of concentration-survival time curves of arsenite-injected roaches having different resistances, J. F. YEAGER and S. C. MUNSON. (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 39 (1946), No. 1, pp. 145-151, *illus.* 2).—Analysis of previous data led to certain indications of the reasons why some cockroaches injected with a given dose of sodium metarsenite survived for short times, whereas others similarly injected survived longer. An interpretation of the results indicated that such differences in survival times are associated with and may be in part caused by (1) differences in the electrolytic dissociation of the poison in the insect blood, which may involve differences in the degree of dissociation at high concentrations, the rate of change in degree of dissociation with change in concentration, and the concentration at

which complete dissociation is attained; and (2) by differences in the capacity of the insect to render ineffective some of the poison received or in the amount of vital tissues, or differences in both. It is suggested that among the physiological factors that may be involved are blood volume and plasma chemical composition and processes of detoxification and excretion. The findings are also in accord with the idea that the mixing of the poison with, and its distribution by, the blood occur more slowly in those insects that have longer survival times.

Investigations at the Henry R. Carter Memorial Laboratory of the United States Public Health Service, S. W. SIMMONS (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 15-17).—This laboratory at Savannah, Ga., is the technical development unit for supplying information on procedures, materials, formulas, and equipment for immediate practical field use. Its activities—here briefly summarized as to work, purpose, and significance—are divided into the nine units on anopheline residual sprays, anopheline larvicides, insect premise sanitation, equipment development, effects of DDT anopheline larviciding on wildlife, typhus control investigations, anopheline host preference studies, chemical investigations, and the insectary for producing large numbers of specimens for the various projects.

Histological effects of sesamin on the brain and muscles of the housefly, A. HARTZELL and E. WEXLER (*Contrib. Boyce Thompson Inst.*, 14 (1946), No. 3, pp. 123-126, illus. 1).—Sesamin was found to produce characteristic effects on the brain and striated muscles of moribund houseflies in a preliminary histological study of tissues stained with Delafield's hematoxylin and eosin Y. The principal effect was the vacuolation of the larger nerve cells of the brain and the accentuation of the nodes and Krause's membrane in the striated muscles. The effects of pure sesamin on brain and muscle tissues of the housefly were in general similar to those obtained with sesame oil. Histological evidence is presented that the active principle of sesame oil is sesamin.

The Bodian technic and the mosquito nervous system, W. M. ROGOFF (*Stain Technol.*, 21 (1946), No. 2, pp. 59-61).—Fixation of mosquitoes by Petrunkevitch's para-nitro-phenol fluid with 20 or 25 percent formalin allowed use of the Bodian activated protargol technic where other commonly employed fixing fluids were unsuccessful. Gold-toning with subsequent oxalic acid reduction proved necessary for culicid nerve tract preparations.

Identification of *Culex* males under low magnification, H. R. DODGE (*Ann. Ent. Soc. Amer.*, 39 (1946), No. 1, pp. 140-124).—The purpose of this study was to set forth characters whereby the ♂♂ of the 10 species of this mosquito genus occurring in Georgia can be distinguished by the low powers of the binocular microscope. An identification key is provided.

DDT emulsion applied to rice-field water to control mosquitoes, C. B. WISECUP, W. C. BROTHERS, P. M. EIDE, and C. C. DEONIER. (U. S. D. A. et al.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 52-55).—Large-scale tests of the effectiveness of DDT in controlling *Anopheles* and *Psorophora* mosquito larvae were conducted during May 25-September 4, 1944, in rice fields near Stuttgart, Ark. A basic concentrate consisting of 20 percent of DDT, 60 percent of xylene, and 20 percent of Triton X-100—diluted with water to form emulsions of various strengths—was applied to flowing irrigation waters. Weekly surveys of 16 treatments on over 730 acres led to the following conclusions: The method is feasible for controlling mosquitoes in fields up to 70 acres in extent when the irrigation flow is about 1,000 gal. per minute. Treatments should be applied close to the point where the water

enters the field and at about 1 part DDT per million of water to insure long-lasting results. It is imperative, however, that more satisfactory equipment be developed for the application of DDT to flowing water. The emulsions used in these tests did not injure the current rice crop.

**Aerosol formulation:** Laboratory tests with pyrethrum and DDT aerosols against the common malaria mosquito and the housefly, A. W. LINDQUIST, B. V. TRAVIS, A. H. MADDEN, and H. A. JONES. (U. S. D. A.). (*Soap and Sanit. Chem.*, 22 (1946), No. 5, pp. 135-143, illus. 1).—In laboratory tests to find substitutes or adjuvants for pyrethrum in aerosols, promising results were obtained with DDT. Since the latter is only slightly soluble in dichlorodifluoromethane, it became necessary to find an auxiliary solvent. From the standpoints of availability, cost, odor, nonirritating properties, and non-toxicity to men, cyclohexanone was considered the best one tested; 10 percent of it plus 5 percent DDT in an aerosol formula caused a 24-hr. kill of the common malaria mosquito close to that obtained with a pyrethrum aerosol containing 0.4 percent of pyrethrins and 8 percent of sesame oil, and was far better than the pyrethrum aerosol against houseflies. Compared with pyrethrum, DDT gave a slower knock-down of both mosquitoes and flies. In contrast, however, a large percentage of flies recover after exposure to pyrethrum, whereas recovery seldom occurred after DDT exposure; recovery of mosquitoes from exposures to either DDT or pyrethrum was negligible. To increase the speed of knock-down of the 5 percent DDT formula, 0.2 percent of pyrethrins was added; this combination proved highly effective against both mosquitoes and flies. Tests of various mineral and vegetable oils as possible substitutes for sesame oil indicated that corn oil and motor oils can be used effectively in the pyrethrum aerosol; addition of the latter also increased the effectiveness of DDT.

**Water level relationships of plants in the Tennessee Valley with particular reference to malaria control,** T. F. HAIL, W. T. PENFOUND, and A. D. HESS (*Jour. Tenn. Acad. Sci.*, 21 (1946), No. 1, pp. 18-59, illus. 10).—Information is presented on seed germination, sprouting, survival, and growth form of littoral plants in relation to water levels; the detailed data are based on 4-yr. observations of 11 reservoirs, 3 natural ponds, and 2 experimental pools in the Tennessee Valley. Three major groups each of herbs and woody plants are recognized in relation to water tolerance, viz, intolerant, moderately so, and tolerant. The findings are applied in a program of malaria control on impounded waters through water level management, four types of water level schedules being used: Combined schedule for main river reservoirs, cyclical fluctuation schedule, water level recession schedule, and constant pool, each of which is fully discussed. There are 34 references.

**Studies of the physiology and toxicology of blowflies.**—X, A histochemical examination of the distribution of copper in *Lucilia cuprina*. XI, A quantitative investigation of the copper content of *Lucilia cuprina*, D. F. WATERHOUSE (*Austral. Council Sci. and Indus Res. Bul.* 191 (1945), pp. 39, illus. 7).—Studies of Cu in blowflies were undertaken to follow investigations made of Fe absorption and metabolism and for several reasons, paramount among which were the facts that Cu is of universal occurrence in plants and animals and that its function in the organism is closely linked with and in many instances analogous to that of Fe. Histochemical staining tests with sodium diethyl-dithio-carbamate revealed Cu accumulations in two zones of the acid midgut of full-grown larvae; the malpighian tubules also stained distinctly, but the rest of the body tissues exhibited no indication of the presence of Cu. As the amount of Cu in the larval medium was increased, a greater amount

was accumulated by the midgut; with progressive stages of increase, stages were reached at which growth was appreciably retarded and finally inhibited. As to quantitative determinations, the Cu concentration in the eggs was 5.9 percent of the dry tissue; that in the newly hatched larvae was higher than at any other stage in larval or pupal life. The content fell rapidly during initial growth, reaching the low level of 2.3 mg. percent at 1.5 days and then gradually rising to 3.9 in the pupae. This trend continued until the adult stage, with a final Cu concentration of 6.2 mg. percent. Larval blood contained 0.2 mg. percent Cu. A third to a half of the larval Cu was water-soluble; a similar amount was extracted with 0.5 N HCl. In the eggs, water-soluble Cu formed about a third of the total Cu and a further third was detached by dilute HCl.

**DDT for the control of the horn fly in Kansas, E. W. LAAKE.** (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 65-68, illus. 1).—The objects of these cooperative tests (1945) were to determine the duration of effectiveness of DDT sprays and dips against the horn fly under field conditions and its value to the cattleman for controlling this pest, and to familiarize livestock owners with the proper use of the chemical for treating animals against flies and other external parasites. When all animals in a herd were sprayed, the average duration of effectiveness increased with each treatment, but when only half were sprayed the duration was no greater after the third than after the second spraying. Four dippings of 0.1 percent DDT were effective for as long a time as the four sprayings with 0.2 percent DDT, but dipping required about three times the amount of chemical. The tests gave important information, not only on the effectiveness of DDT against the horn fly but on the amount of damage done by it to the cattle industry; estimates based on one of these tests indicated that the loss of beef due to horn fly injury would amount to 85,980,000 lb., or a value of approximately \$8,598,000. Residual sprays applied to barns for control of houseflies and stableflies showed that nine barns sprayed with a 5 percent DDT emulsion were practically free of these pests for 73 to 98 days.

**DDT to control hornflies and Gulf Coast ticks on range cattle in Florida, J. G. MATTHYSSE** (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 62-65).—Spraying and dipping of 8,402 beef cattle in 36 herds in southern Florida for control of horn flies by DDT indicated the following: The extremes of summer weather—particularly heavy daily downpours—quickly rendered inactive the deposits from low-concentration sprays. Deposits from suspensions resisted inactivation better than those from emulsions. Deposits from sprays of 1 percent or more DDT suspensions remained lethal to horn flies for almost 2 weeks and kept horn fly populations on whole herds at insignificant levels for over a month; deposits from sprays of 1.5 and 2.5 percent DDT suspension remained active little if any longer, and the much higher cost of the 2.5 percent renders it of doubtful value. For long-lasting residual action from emulsions it appears that at least 2.5 percent DDT is required in the spray. Dipping proved more effective at equal concentration than spraying but requires so much more material that it is of doubtful practicability; spraying with 1 percent DDT is far cheaper than dipping in 0.25 percent. A very rapid and effective method of spraying is to arrange many nozzles inside a chute so as to cover the whole body as the cattle run through the spray. The treatment apparently reduced mosquito populations in some cases, but had little effect on tabanids. Inclusion of DDT in adhesive sprays or greases applied to the ears of cattle markedly reduced the incidence of screwworm ear cases predisposed by Gulf Coast tick infestations.

A new method for the control of cattle ticks in tropical regions, R. L. SQUIBB (*Jour. Anim. Sci.*, 5 (1946), No. 1, pp. 71-79, illus. 1).—The new combined solution showed excellent possibilities for use as a spray for controlling and possibly eradicating the cattle fever tick (*Boophilus microplus*). With co-operation of the cattlemen, this method, which appears to kill ticks over a 7-day period, can be more rapid at effecting complete eradication than any of the methods now being employed in the tropics. Tests indicated that a DDT-rotenone combination (detailed formula given) is superior to either used alone, and that increasing the percentage of DDT in the combined solution fails to increase the kill; there were indications that a reduced percentage of DDT in the combined solution was not as efficient. The combined solution worked equally well under dry or wet tropical lowland conditions; in one group of field tests, a continuous rainfall of 8 hr. following application did not interfere with an average kill of 93 percent. Observations over 6 mo. on 1,000 sprayed animals failed to indicate any poisonous or continued irritating effects. An animal covered with 80 to 150 cc. of the solution gave an 85 to 99 percent kill within 7 days after application. A fine penetrating spray proved most efficient; the mortality percentage was definitely related to this spray technic. An apparent progressive killing action was observed to last as long as 7 days; the percentage kill effected was as follows: 24 to 48 hr. after application, 20 to 55; at 48 to 96 hr., 55 to 85; and at 96 to 168 hr., 85 to 99. Infestation of the men working in heavily infested pastures was prevented by spraying 20 cc. of the combined solution over their trousers.

Ticks found in New York State, D. W. BAKER. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 84-90, illus. 18).—An address.

Preliminary tests with DDT for single-treatment eradication of the swine louse *Haematopinus suis*, H. E. KEMPER and I. H. ROBERTS. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 829, pp. 252-254).—Three groups of pigs—all heavily infested with this louse and maintained under average farm conditions—were treated once only with DDT in mineral oil and water emulsions. Sprays containing 0.1 and 0.5 percent DDT—each tested on 1 sow and 7 litter-mate pigs—destroyed all motile lice within 4 hr. but not all young lice hatching thereafter. Only 3 lice, however, were found 8 weeks after treatment with the higher concentration. A dip containing 0.75 percent DDT—tested on 300 heavily infested pigs—not only killed all motile lice within 4 hr. but continued to destroy newly hatched lice thereafter and effectively eradicated this pest from the herd. The nits were not killed by the DDT emulsions used, young lice continuing to hatch but dying after contact with the hairs and skin of treated animals.

A. L. 63, the original British Army louse powder, H. J. CRAWFORD-BENSON and J. MACLEOD (*Jour. Hyg. [London]*, 44 (1946), No. 4, pp. 294-306, illus. 3).—The problem of louse control by powders consists in killing the pests at time of treatment and preventing reinfestation; in the tests reported, no single insecticide fulfilled both functions. The work has shown the necessity of using laboratory tests ("cell tests") in conjunction with insecticide tests on the parasite living under natural conditions; the technic and results from both are described in detail. In the field trials, spontaneously infested persons living in verminous surroundings were treated and observed daily for each preparation. Naphthalene proved the most effective insecticide for quick killing but failed to prevent reinfestation. Derris and pyrethrum were toxic to the body louse, but either alone or in combination proved inferior to certain other materials. The combination of high-boiling-point tar acids with derris resulted in a material more toxic to lice than either alone; this was found

to be an activation effect, and the theory of activation is discussed. Activated derris (referred to as A. L. 63) though slow in killing power, was shown to be the best preparation tried for prevention of reinfestation; the formula for its preparation in percentages in high-boiling-point tar 2, derris root 14.3, naphthalene 50, and China clay 33.7. When applied to the clothing of an infested individual, A. L. 63 killed 95 percent of all lice present within 24 hr. and gave complete protection against reinfestation for an average of 5 days and partial protection for 8 days; applied to clean garments as a prophylactic, it gave complete protection for 7 to 8 days and partial protection for about 16 days. Individuals living in a verminous environment and wearing one shirt continuously for a month without washing were protected from infestation by treating the inside of the garment at 8-day intervals. A brief history of the use of this insecticide in the British Army during 1940-44 is given.

**Value of DDT for the control of the northern feather mite *Liponyssus sylviarum*, M. L. POVAR** (*Cornell Vet.*, 36 (1946), No. 1, pp. 91-92).—Finely powdered sulfur was not found observably toxic to this mite, but it acted as a repellent. Ten percent DDT powder dusted on birds—though somewhat toxic to the mite—did not prove sufficiently effective to replace treatment with nicotine sulfates.

**Observations on the habits and life history of a chigger mite, *Eutrombicula batatas* (Acarina: Trombiculinae), C. D. MICHENER** (*Ann. Ent. Soc. Amer.*, 39 (1946), No. 1, pp. 101-118, illus. 34).—The author presents the results of studies of the life history of one of the species of chiggers most commonly encountered in Panama. Such studies of this group are especially important from the standpoint of disease transmission. Since an individual feeds on a vertebrate host only once during its life, the disease organisms must pass from the larva of one generation through all the successive stages—including the egg—to the larva of the next generation.

**A note on the culturing of chiggers (Trombiculidae), R. MELVIN** (*Ann. Ent. Soc. Amer.*, 39 (1946), No. 1, pp. 143-144).—A satisfactory culture medium for most of the species of chiggers studied consisted of soil and chicken manure from the floor of a chicken house; details of the technic are given.

**The composition and origin of a white deposit found in galleries of a wood boring insect in two samples of the wood of *Qualea* sp., W. G. CAMPBELL, D. F. PACKMAN, and D. M. ROLFE** (*Empire Forestry Jour. [London]*, 24 (1945), No. 2, pp. 221-223, illus. 1).—The white deposit observed was found to be aluminum succinate. There appeared to be little doubt that it arose as the direct result of a flow of the tree sap into the cavities created by a wood-boring insect. These galleries were identified as typical of the workings of larvae of a longhorn beetle (Cerambycidae).

**Sulfa drugs to control American foulbrood, L. HASEMAN.** (Univ Mo.). (*Jour. Econ. Ent.*, 39 (1946), No. 1, pp. 5-7).—The author's experimental evidence has convinced him that sulfathiazole fed in sugar sirup or in pollen substitute will give an effective control of American foulbrood—used either as a preventive or a clean-up remedy. A thorough clean-up of a colony may protect it against reinfection for two seasons, but feeding the drug each spring and fall is advised, or whenever infection appears as a part of the regular apiary routine. In severe cases, it will pay to relieve colonies of their worst combs, rendering them and replacing with full sheets of foundation or drawn combs. Full directions for use of the method are given.

## ANIMAL PRODUCTION

Effect of maturity on the chemical composition and digestibility of the stems and leaves of sweetclover hay, J. SOTOLA. (Wash. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 72 (1946), No. 12, pp. 365-371).—In tests carried on in 1939 and 1940, plants of Madrid sweetclover steadily increased in leaf percentage as they matured during the first year, but decreased at an even greater rate in leaf percentage during the second year. The plants decreased in protein, fat, and ash and increased in crude fiber as they matured during the first year. As the second-year growth progressed, the plants decreased sharply in protein and increased in crude fiber, much more so than during the first year. The leaves in both first- and second-year crops showed some decrease in protein, but the decrease was much less than that in the whole plant.

Digestion experiments in which sheep were fed Spanish sweetclover showed the first-year crop, cut for hay when 36 in. high, to contain 6.36 percent digestible crude protein and 52.59 percent total digestible nutrients. The second-year crop, more fibrous and stemmy, contained 11.94 percent digestible crude protein and 44.25 percent total digestible nutrients. Leaf protein, on the average, was 45 percent more digestible than protein of the stems in both the first- and second-year crops.

A study on the vitamin A activity of carotene in green fodder, B. C. R. SARKAR and K. C. SEN (*Jour. Agr. Sci. [England]*, 36 (1946), No. 2, pp. 95-99).—In order to determine the vitamin A value of carotene in different green fodders, an investigation was made of (1) the relation between the chemically determined carotene and its biological activity as compared with that of standard carotene, (2) the purity of the apparent carotene from different sources, (3) the absorption of carotene in rats, and (4) the relative efficiency of the standard carotene and preformed vitamin A. Biological tests indicated the chemical method of assay to be a fair index of the true carotene content of green fodders, and carotene as an extract to be quite as effective in the system as that in plant tissues.  $\beta$ -Carotene is apparently predominant in these materials. Carotene in green fodders as estimated chemically is about 85 to 98 percent pure as shown by chromatographic adsorption through dicalcium phosphate; in other roughages a considerable part is noncarotene in nature. Fecal excretion of true carotene by rats at the 1- to 2- $\mu$ g. level of dosage is shown to be 10 to 13 per cent according to the biological method, although the apparent excretion is as high as 40 to 52 percent. When the standard carotene is compared biologically with cod-liver oil vitamin A, the former is found to be only about half as active as an equal weight of the latter. On this basis, the vitamin A value of the various green fodders is only half their true carotene contents.

Studies in the chemistry of grass silage, J. G. ARCHIBALD. (Mass. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 72 (1946), No. 8, pp. 277-287).—The author reports upon a biochemical investigation based on 40 samples of the fresh green crops from which the silages sampled were made.

It was found that variations due to the kind of crop used were more significant than those due to the action of the preservative. In general, legume silages had lower pH values and higher total acidity than had the silages made from grasses or small grains. The type of acidity also was different. Legume silages were characterized by a high lactic acid content, while the others showed relatively large amounts of acetic and butyric acids. The most strongly acid-smelling silages were frequently the least acid, as judged

measured by pH or total titratable acidity. This is tentatively explained on the ground that butyric acid has an acidic odor much stronger than that of lactic acid, while at the same time the butyric fermentation produces more ammonia, which neutralizes an equivalent quantity of the acid, than is formed in a lactic acid fermentation. The corn silages differed sharply from the grass silages in having lower pH values, very low volatile base content and no butyric acid, and high lactic and acetic acid content.

Of the preservatives used, molasses and ground wheat seemed the only ones at all effective. Salt and lactic acid cultures were in many respects inferior to no preservative at all. Urea was apparently entirely unsuitable for the purpose.

Changes in proximate composition due to the fermentation process showed a definite trend regardless of the nature of the crop ensiled. High carotene values were not always found in silages that were of good quality in other respects. Carotene losses in some of the large silos were excessive.

Small containers utilized in an effort to speed up the work did not prove satisfactory, losses due to rotting and mold being excessive. Conditions existent in a large silo were found not readily duplicated on a small scale. Silage made from wilted alfalfa was quite different in composition from that made from the unwilted crop. The chloride content of some of the silages in which salt was used as a preservative was above the optimum for reasonable intake of salt, and in some samples it was excessive.

Losses in total nitrogen, as indicated by determinations in both the fresh and the dried ground samples, were very variable, being much higher in the silages than in the corresponding green crops. Certain preservatives (molasses and ground wheat) tended to minimize this loss.

The chromatographic procedure for determining carotene gave results consistently somewhat lower than those obtained by the Official (E. S. R., 85, p. 5) phasic separation procedure.

Quarterly report on official feed samples analyzed by the feed and fertilizer department, Kentucky Agricultural Experiment Station (*Kentucky Sta. Regulat. Bul. 46 (1946), pp. 8*).—These analyses cover the quarter ended March 31, 1946.

Blood levels of calcium and inorganic phosphorus in Hereford cattle, M. G. PAYNE, A. G. CLARK, H. E. KINGMAN, and W. M. STANSBURY. (Colo. Expt. Sta. et al.). (*Jour. Agr. Res. [U. S.], 72 (1946), No. 12, pp. 357-363*).—Based on analyses of samples from 560 animals, the normal blood levels of phosphorus and calcium for range Hereford yearling and herd bulls and for range Hereford heifers and aged cows have been determined. The normal levels for blood serum inorganic phosphorus in milligram percent was  $7.30 \pm 0.103$ ,  $4.76 \pm 0.099$ ,  $5.07 \pm 0.063$ , and  $4.89 \pm 0.101$  for yearling bulls, herd bulls, 2-year-old heifers, and aged cows, respectively. The phosphorus level of blood was found to be greater in bulls than in cows. The quantity of phosphorus diminishes with age in Hereford range cattle, but this relationship with age is stronger in the male animal.

The normal levels for blood calcium in milligram percent were  $10.46 \pm 0.238$ ,  $13.03 \pm 0.256$ ,  $9.13 \pm 0.158$ , and  $9.52 \pm 0.249$  for yearling bulls, herd bulls, 2-year-old heifers, and aged cows, respectively. A complementary association of phosphorus and calcium has been found as shown by the fact that  $r = 0.39 \pm 0.129$  for yearling bulls,  $-0.03 \pm 0.192$  for herd bulls,  $-0.25 \pm 0.117$  for 2-year-old heifers, and  $0.01 \pm 0.140$  for aged cows. The calcium-phosphorus ratio in homogeneous groups was found to be a variable concept depending on age and sex.

From corn cobs and shucks to beef, J. E. FOSTER (*Res. and Farming [North Carolina Sta.]*, 4 (1946), *Prog. Rpt.* 2, p. 9, *illus.* 1).—This is a brief account of a 114-day feeding test with 23 grade Hereford steers, in which those fed a ration containing corn shelled and coarsely ground gained 2.21 lb. per day per head, as compared with 2.02 lb. for a similar lot receiving coarsely ground whole ears and shucks.

Lamb production and feeding in the El Paso Valley, J. M. and J. H. JONES. (Tex. Expt. Sta.). (*Sheep and Goat Raiser*, 26 (1946), No. 8, p. 21).—Feeding tests with 255 head of Rambouillet lambs in 10 lots for 119 days are reported in which heavy feeder lambs reached satisfactory finish by long feeding on alfalfa hay with limited amounts of milo grain. Except for a possible saving in labor, there was nothing to recommend the deferred feeding of grain, even in long feeding. Gains were about as good on lambs fed 43 percent protein cottonseed cake as for an equal amount of milo, but the carcasses of the milo-fed lambs graded higher. First and fourth cutting alfalfa were of equal value. Lambs fed the larger amounts of concentrates returned the heavier carcasses.

The weaning of piglets at an early age, W. A. VERBEEK (*Farming in So. Africa*, 21 (1946), No. 241, pp. 271–275, *illus.* 1).—An experiment comparing the growth of pigs weaned at approximately 3 weeks and 8 weeks indicated that pigs may be successfully weaned at an early age, but it is pointed out that the work is still in its initial stages, especially as to the economic value of the practice.

Effect of diet on efficiency of egg production, H. R. BIRD and D. WHITSON. (U. S. D. A.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 210–214).—In two experiments of 16 weeks' duration, groups of 50 yearling Rhode Island Red hens were fed diets differing in fiber and ash content, and their relative efficiencies of feed utilization were calculated by means of a partition equation. In the first experiment the group fed the diet containing 6.53 percent of ash and 2.56 percent of fiber achieved an efficiency 0.98 times the calculated value, and the group fed the diet containing 9.28 percent of ash and 5.89 percent of fiber was 0.87 times as efficient as calculated. In the second experiment the ratios of observed to calculated efficiencies were 1.13 for the low-ash, low-fiber diet; 1.17 for the high-ash, low-fiber diet; 0.95 for the low-ash, high-fiber diet; and 0.90 for the high-ash, high-fiber diet. It is concluded that a level of 5.89 percent of fiber in a laying mash is sufficient to exert a detrimental effect on efficiency of feed utilization, but not on level of egg production when the fiber is contributed largely by wheat mill feeds, oats, and alfalfa meal.

The utilization of food elements by growing chicks.—XI, A comparison of ground wheat and ground rye in rations for growing chicks, C. W. ACKERSON, W. E. HAM, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul.* 146 (1946), pp. 5).—Continuing this series (E. S. R., 95, p. 378) and using 2 lots of 17 or 18 newly hatched Dark Cornish × White Leghorn chicks and a 6-week feeding period, either ground wheat and dextrin or ground rye was fed to furnish in each case 25 percent of the protein of the entire mixed ration. The wheat-fed lot made a significantly greater gain than the rye-fed lot. Several cases of curled-toe paralysis occurred in the two lots, and a tendency to cannibalism appeared in the rye-fed lot.

Effectiveness of dietary supplements in increasing hatchability of eggs and viability of progeny of hens fed a diet containing a high level of soybean oil meal, H. R. BIRD, M. RUBIN, D. WHITSON, and S. K. HAYNES. (U. S. D. A.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 285–293, *illus.* 1).—In confirma-

tion of an earlier report (E. S. R., 94, p. 789). it was found that the eggs of hens fed 30 percent of soybean oil meal as the sole protein supplement were low in hatchability. During a period of 43 weeks only 66 percent of the fertile eggs of these hens hatched, compared with 84 percent hatchability of the fertile eggs of hens fed a good breeder mash containing sardine meal as the only protein supplement. The deficiency of the basal diet containing 30 percent soybean oil meal was corrected by the inclusion of 5 percent cow (or steer) manure, 10 percent sardine meal, or 10 percent dried skim milk; the hatchability of fertile eggs produced by hens fed these supplements was, respectively, 82, 78, and 79 percent. The favorable effect of the sardine meal supplement was delayed, being first observed during the third month of the experiment. A similar delay occurred before the full effect of the other two supplements was observed, but a partial response was noted during the first 2 mo. Inclusion of corn gluten feed or extra  $\text{MnSO}_4$  in the diet did not improve hatchability, and the response to wheat or butyl fermentation solubles was doubtful.

The deficiency of the basal diet containing 30 percent soybean oil meal was revealed not only by low hatchability but by low viability of chicks hatched. Mortality during the first week of life ranged from 16 to 38 percent in different hatches as compared with 1 to 11 percent for the offspring of the birds fed the positive control diet. The effectiveness of modifications of the hens' diet in improving the viability of chicks paralleled effectiveness in improving hatchability, pointing to the likelihood that low hatchability and low viability are manifestations of the same deficiency. Supplementation of the chicks' diet was not effective in improving viability. The most consistent post-mortem findings in the chicks were kidney damage, urate deposits in the ureters, and distended gall bladders.

The blood vessels and "ground color" of irises of pigment-free Single Comb White Leghorns, R. F. BALL. ([N. Y.] Cornell Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 242-245, illus. 5).—A detailed description is given of the vascular system and ground color of the pigment-free irises obtained by feeding from hatching to 280 days of age a ration devoid of the yellow carotinoid pigments. In these irises four distinct and regular zones of color were distinguishable.

The significance of the level of riboflavin in the ration of breeding birds, D. R. CLANDININ (*Poultry Sci.*, 25 (1946), No. 3, pp. 223-231, illus. 2).—This study dealt with the effect of the level of riboflavin in the hen's diet on (1) the riboflavin content of fresh eggs, incubated eggs, and the livers of day-old chicks and (2) the growth, incidence of curled-toe paralysis, and riboflavin content of the livers of chicks fed rations containing varying amounts of riboflavin.

The results confirmed the findings of earlier workers that the level of riboflavin in the ration of breeding birds influences the amount of this vitamin that is present in their eggs, and that the developing embryo does not synthesize riboflavin. It is also concluded that "the level of riboflavin in the ration of breeding birds influences the amount of this vitamin that is present in chicks at hatching time; the amount of riboflavin that is present in chicks at hatching time influences their growth and incidence of curled-toe paralysis when they are fed rations that are adequate or inadequate in riboflavin; the riboflavin content of the livers of chicks (and no doubt the riboflavin content of the chicks themselves) during the first 4 weeks of life is closely correlated with their growth and incidence of curled-toe paralysis; the riboflavin content of the livers of chicks (and no doubt the riboflavin content of the chicks

themselves) during the first 4 weeks of life is closely correlated with the amount of this vitamin that is present in the chicks at hatching time and with the amount of this vitamin that is present in the chicks' diet; the amount of riboflavin present in chicks at hatching time has an important influence on their rate of growth during the first week or two after hatching; and the amount of riboflavin present in the chicks' diet has an important influence on their rate of growth during the third and fourth week after hatching."

**The influence of nicotinic acid on the response of chicks receiving a diet high in corn.** H. M. SCOTT, E. P. SINGSEN, and L. D. MATTERSON. ([Conn.] Storrs Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 303-304).—In studies in which a lot of 10-day-old chicks receiving a diet of 76.4 percent of ground yellow corn made a satisfactory growth response during 25 days as compared with a check lot when the ration was supplemented adequately with the available crystalline vitamins of the B-complex, particularly nicotinic acid, there was complete protection from perosis, found in 9 of the 10 chicks in the check lot, and the usual poor feathering ascribed to diets containing large percentages of corn was not observed.

**Influence of gelatin and tryptophane on nicotinic acid requirement of chicks.** G. M. BRIGGS. (Md. Expt. Sta.). (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 749-750).—Day-old chicks were fed a basal diet low in arginine, glycine, and nicotinic acid. When 10 percent gelatin was added (as the source of arginine and glycine), depression in the growth rate and black-tongue occurred. The further addition of nicotinic acid (5 mg./100 gm. diet), or 0.1 or 0.2 percent *dl*-tryptophan, counteracted these effects. The replacement of the gelatin by 0.5 percent *l* (+)-arginine HCl + 3 percent glycine produced fair growth and eliminated the symptoms of black-tongue. Further addition of nicotinic acid or tryptophan to the amino acid mixture merely increased the growth rate slightly.

These studies seem to indicate that the presence of gelatin in the ration greatly increases the nicotinic acid requirement of the chick fed a purified diet.

**The activity of synthetic folic acid in purified rations for the chick.** T. D. LUCKEY, P. R. MOORE, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Science*, 103 (1946), No. 2684, pp. 682-684, illus. 1).—Reduced growth, poor feathering, and low hemoglobin and hematocrit values consistently obtained by feeding a basal ration to chicks were prevented by the addition of 25 $\gamma$  of synthetic folic acid per 100 gm. of the ration. More than 25 $\gamma$  were needed when the diet contained sulfasuxidine. Evidence for the possible indirect action of folic acid is summarized.

Vitamin C or whole liver powder gave a slight response in the presence of adequate amounts of synthetic folic acid.

The basal ration consisted of dextrin, 61; casein, 18; gelatin, 10; 1-cystine, 0.3; salts V (E. S. R., 89, p. 580), 6; soybean oil, 5;  $\alpha$ -tocopherol, 0.3 mg.; 2-methyl-1,4-naphthaquinone, 0.05 mg.; thiamine. HCl, 0.3 mg.; riboflavin, 0.6 mg.; Ca pantothenate, 2 mg.; choline, Cl, 150 mg.; nicotinic acid, 5 mg.; pyridoxine · HCl, 0.4 mg.; biotin, 0.02 mg.; and *l*-inositol, 100 mg. In addition 1,700 U. S. P. units of vitamin A and 170 A. O. A. C. units of vitamin D<sub>2</sub> were administered by dropper.

**Observations on monomethylaminoethanol and dimethylaminoethanol in the diet of chicks.** T. H. JUKES, J. J. OLESON, and A. C. DORNBUSH (*Jour. Nutr.*, 30 (1945), No. 3, pp. 219-223).—Monomethylaminoethanol and dimethylaminoethanol were found to prevent perosis in chicks when added to a purified diet which was deficient in choline. Growth was promoted by dime-

thylaminoethanol but not by monomethylaminoethanol. The addition of methionine to the diet did not stimulate growth, but growth was increased when methionine was added to the basal diet plus monomethylaminoethanol or to the basal diet plus dimethylaminoethanol.

Experiments were also made with a basal diet deficient in both methionine and choline. Growth was not stimulated by dimethylaminoethanol unless methionine was also added. Chicks receiving the basal diet did not develop perosis, but perosis developed in chicks receiving the basal diet plus methionine.

See also a note by Jukes and Oleson (E. S. R., 95, p. 94).

A nutritionally produced cerebellar disorder in chicks, not associated with E avitaminosis, F. H. BIRD. (Univ. Calif.). (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 747-748).—Chicks were fed a highly purified diet of the following composition per 100 gm.: "Water-washed casein 22.2, l(+)-arginine monohydrochloride 0.3, glycine 0.9, l(-)-cystine 0.4, calcium gluconate 5.0, cellulose (Cellu flour) 5.0, soybean oil 3.0, fish oil (sardine) (3000 A-400 D) 0.25, sodium chloride mixture containing 0.49 percent manganese, 0.1 percent copper, 0.05 percent zinc, 0.05 percent aluminum, 0.002 percent cobalt, and 0.04 percent iodine 1.0,  $\text{Ca}_3(\text{PO}_4)_2$  3.5,  $\text{K}_2\text{HPO}_4$  1.3, KCl 0.3,  $\text{MgSO}_4$  0.1,  $\text{Na}_2\text{SiO}_3 \cdot 9\text{H}_2\text{O}$  0.25, cholic acid 0.1, choline chloride 0.2, and glucose (cresolose) 56.2 gm. To every 100 gm. of the above mixture were added solubilized liver eluate equivalent to 4 gm. of solubilized liver, thiamine hydrochloride 0.5 mg., pyridoxine hydrochloride 0.4 mg., riboflavin 0.5 mg., d-calcium pantothenate 1.5 mg., nicotinic acid 1.0 mg., 2-methyl-1, 4-naphthohydroquinone diacetate 1.0 mg., synthetic  $\alpha$ -tocopherol (Merck) 1.0 mg., and biotin 0.01 mg."

On this diet, the chicks developed a disorder characterized by convulsions and lack of coordination. Histological examination of the brain revealed cerebellar lesions. Adequate supplements of vitamin E (synthetic  $\alpha$ -tocopherol) did not prevent this disorder.

Calcium, phosphorus, and vitamin D interrelationships in the nutrition of the growing chick, J. S. CARVER, R. J. EVANS, and J. MCGINNIS. (Wash. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 294-297).—Growth and bone ash findings with 900 day-old White Leghorn cockerels on 45 different diets indicated an interrelationship between the levels of calcium, phosphorus, and vitamin D in the diet. The results showed that the amounts of calcium and phosphorus, as well as their ratios, are of importance if optimum growth and bone ash are to be obtained.

When no supplementary vitamin D was added to the diets, a progressive improvement in the growth and percentage of bone ash were obtained by increasing the phosphorus content of the diet from 0.5 to 0.8 percent at calcium : phosphorus ratios of 2 : 1 and 3 : 1. At all levels of phosphorus, a 4 : 1 calcium : phosphorus ratio caused a depression in both growth and percentage of bone ash. When vitamin D was added to the diet, a level of 20 A. O. A. C. chick units gave satisfactory growth and bone ash with the 0.8- and 1.0-percent levels of phosphorus at calcium : phosphorus ratios of 2 : 1 and 3 : 1.

Increasing the vitamin D to 60 A. O. A. C. chick units at the above phosphorus levels and calcium : phosphorus ratios did not improve growth or bone ash. On the other hand, at the 1 : 1 calcium : phosphorus ratio and at all levels of phosphorus fed, 60 A. O. A. C. chick units gave better growth and calcification than 20 units. At a 2 : 1 ratio and 0.5 and 0.6 percent phosphorus levels, 60 units gave better growth and calcification than 20 units. Neither the 20- nor the 60-unit level of vitamin D improved growth at the

4 : 1 ratio of calcium to phosphorus over the corresponding groups fed no vitamin D.

**Phosphorus in poultry nutrition.—II, Sodium acid phosphate, tri-calcium phosphate, and bonemeal as sources of phosphorus for the growing chick,** E. P. SINGSEN and H. M. SCOTT. ([Conn.] Storrs Expt. Sta.) (*Poultry Sci.*, 25 (1946), No. 3, pp. 302–303).—Continuing this series (E. S. R., 94, p. 368), feeding experiments with 3 lots of 25 chicks each are reported. Growth and bone ash data revealed that the phosphorus of all three supplements was readily and equally available for bone calcification, that growth was very similar on all three phosphorus supplements, and that 0.45 percent available phosphorus in the diet will support excellent growth and bone calcification in the chick. “The results support the conclusion that the phosphorus of bonemeal and tricalcium phosphate is as available to the chick as that of sodium acid phosphate, and that experimental data obtained using the latter may be applied with safety to practical poultry diets in which bonemeal and bone-containing products constitute the principal sources of phosphorus.”

**Sources of calcium for laying chickens during hot weather,** B. W. HEYWANG. (U. S. D. A.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 215–222).—During two experiments, calcium gluconate, technical-grade calcium lactate, calcium *d*-lactate, precipitated calcium carbonate, and calcium sulfate were compared with the calcium carbonate of high-grade limestone as sources of eggshell calcium for White Leghorn hens. The ratio of dried-shell weight to whole-egg weight was used as the measure of the relative value of these sources of calcium. Data from the first experiment were grouped into periods when the average maximum air temperature was 67°, 74°, 90°, and 102°F., and those from the second experiment into periods when it was 67°, 74°, 81°, 93°, and 102°. None of the other calcium sources was superior, and calcium sulfate was slightly inferior, to the calcium carbonate of high-grade limestone as a source of eggshell calcium during periods of either relatively high or moderate air temperatures. The different sources of calcium were also similar in their effect on whole-egg weight.

**Calcite grit and granite grit as supplements to a chick starting ration,** G. F. HEUSER and L. C. NORRIS. (Cornell Univ.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 195–198).—The feeding of a granite grit in addition to a complete starting mash did not materially affect the 8-week weights of cockerels reared in batteries, but there was some evidence that feed efficiency was very slightly increased and heavier and larger gizzards were developed.

**The free-choice feeding of a calcium grit showed a slight tendency toward decreased weight.** The addition of 5 percent to the starting mash significantly decreased growth and increased mortality.

**Observations on unabsorbed yolk in chicks,** H. E. LEMASURIER, H. D. BRANION, and F. N. MARCELLUS (*Poultry Sci.*, 25 (1946), No. 3, pp. 300–302).—Barred Plymouth Rock chicks hatched under hens or in incubators and reared with the hen outdoors or with battery brooders or brooder stoves indoors were killed at half-weekly intervals to determine the amount of yolk material remaining in the body cavity. None of the chicks hatched under hens showed any yolk material after 7 days, but unabsorbed yolk was found in many chicks hatched in incubators in all ages up to the end of the 6 weeks' duration of the experiment. In another lot of 200 chicks hatched in an incubator and reared in battery brooders, almost all chicks examined up to 5 weeks of age showed unabsorbed yolk material, and in some cases masses up to ½ in. in length were present after this age. The authors “are inclined to believe that all yolk material remaining in the body cavity of the chick after

1 week from hatching must be regarded as a foreign body, rather than a source of nutrient. It would seem, nevertheless, that presence of this material has little or no influence on growth or livability."

The vitamin D requirements of ducklings, I. MOTZOK, W. D. GRAHAM, H. D. BRANION, and S. J. SLINGER (*Poultry Sci.*, 25 (1946), No. 3, pp. 298-299).—The assays reported indicated a vitamin D requirement for White Pekin ducklings in excess of 30 units per 100 gm. of ration.

The requirement of the turkey poult for vitamin B<sub>1</sub>, L. R. RICHARDSON, A. G. HOGAN, and H. L. KEMPSTER. (Mo. Expt. Sta.). (*Jour. Nutr.*, 30 (1945), No. 3, pp. 151-157, illus. 1).—Turkey poults developed a spastic type of cervical paralysis on rations severely deficient in vitamin B<sub>1</sub> but which contained reasonable amounts of all other required vitamins. The poults which were examined had a lower red cell volume than is normal, but none were markedly anemic. Remission of the symptoms was obtained by the administration of crystalline vitamin B<sub>1</sub>.

Squab raising, A. R. LEE and S. K. HAYNES (*U. S. Dept. Agr., Farmers' Bul.* 684, rev. (1946), pp. 25+, illus. 19).—This is an enlarged and revised edition (*E. S. R.*, 33, p. 872).

## DAIRY FARMING—DAIRYING

Scientific advances in the dairy industry: A review of much literature of the year 1945, J. H. SHRADER (*Jour. Milk Technol.*, 9 (1946), No. 2, pp. 67-100).—Results from an estimated coverage of at least four-fifths of the available literature are reviewed, including about 400 titles.

Reviews of the progress of dairy science: Section A, Physiology of dairy cattle.—I, Reproduction and lactation, J. A. B. SMITH (*Jour. Dairy Res.* [London], 14 (1945), No. 1-2, pp. 195-224).—This review cites 358 references, mainly to the literature from 1940 to 1943.

Variation between breeds in feed cost of milk production, L. COPELAND. (Ky. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 6, pp. 345-348).—Tables are presented showing comparative cost-of-production data for Jerseys and Holsteins in the station herds, two-breed associations in the Louisville area, and all herds finishing a year's testing by the dairy extension department. In all these tables it was observed that Jerseys consistently showed the lowest feed cost per pound of butterfat, while Holsteins produced 100 lb. of milk with the lowest feed cost. However, on a basis of energy value as expressed in 4 percent fat-corrected milk, there was little difference between the respective breeds in feed cost. "Purbred herds apparently produced 4 percent F. C. M. at a lower feed cost than did grade herds."

Carotene utilization in the newborn calf, A. A. SPIELMAN, J. K. LOOSLI, J. W. THOMAS, C. L. NORTON, and K. L. TURK. (Cornell Univ.). (*Jour. Dairy Sci.*, 29 (1946), No. 6, pp. 381-391, illus. 2).—Experiments were conducted with 18 newborn dairy calves to study carotene utilization. Holstein, Guernsey, and Jersey male calves were fed a skim milk-low carotene ration from birth without having received colostrum. Crystalline carotene in peanut oil or lard, alfalfa leaf meal, and a commercial carotene concentrate were used as sources of carotene. Blood plasma levels and liver storage of carotene and vitamin A, growth, and general well-being were used as criteria of carotene utilization.

The onset of infection and scours shortly after birth reduced the absorption and utilization of carotene regardless of the amounts fed. The alfalfa leaf meal and the preparations of crystalline carotene in peanut oil or lard were

unsatisfactory carotene sources. Satisfactory prevention and control of scours was obtained in most cases by oral administration of 4 to 8 gm. of sulfathalidine daily for the first week. When scours were controlled, the calves were able to utilize the carotene in a commercial concentrate at a rate sufficient to provide for satisfactory growth and some storage in vitamin A in the liver.

**Low solids-not-fat content of milk in South Africa, S. W. J. VAN RENSBURG** (*Farming in So. Africa*, 21 (1946), No. 241, pp. 217-228, illus. 6).—The mastitis investigations carried out at Onderstepoort during the past 7 yr. included a study of the various factors which may produce an alteration in the composition of milk. This involved regular bacteriological, physical, and biochemical examinations of milk from the individual quarters of the udders of a herd of grade Friesland cows which were kept free from mastitis over a period of 5 yr. The factors which were shown by these investigations to have a depressing effect on milk solids are (1) bovine mastitis, (2) seasonal and nutritional conditions, (3) stage of lactation, (4) advancing age, (5) general management of dairy cows, (6) individuality, and (7) conformation and structure of the udder.

**A readily prepared medium for the cultivation of the lactobacilli, C. B. McLAUGHLIN** (*Jour. Bact.*, 51 (1946), No. 4, pp. 560-561).

**Influence of yeast extract on *Lactobacillus bulgaricus* incubated at various temperatures, R. J. SWABY** (*Jour. Austral. Inst. Agr. Sci.*, 11 (1945), No. 4, pp. 191-192).—In fermentations conducted at 30° and 49° C. it was apparent that yeast extract encouraged greater cell growth and lactic acid production.

**Effect of unsaturated fatty acids on the acid production of *Lactobacillus helveticus*, E. KODICEK and A. N. WORDEN** (*Nature [London]*, 157 (1946), No. 3993, p. 587).—The experimental results described with  $\alpha$ - and  $\beta$ -elaeostearic, oleic, and elaidic acids are said to be in keeping with the physicochemical hypothesis of the inhibitory effect on growth and acid production, although they do not necessarily exclude a purely chemical interaction.

**The formation of carbon dioxide by lactic acid bacteria and *Bacillus licheniformis* and a cultural method of detecting the process, T. GIBSON and Y. ABDEL-MALEK** (*Jour. Dairy Res. [London]*, 14, (1945), No. 1-2, pp. 35-44).—The amount of CO<sub>2</sub> produced during fermentation of sugars by the heterofermentative lactic acid bacteria depends on several factors: (1) The sugar fermented: Gas is produced more readily from glucose than from lactose. (2) The reaction and buffering capacity of the medium: The optimum initial reaction is about pH 7, and the greater the buffering capacity the more active is the gas production. (3) Factors occurring in plant juices and yeast: These may promote gas formation without increasing cell proliferation and apparently have a specific effect on the fermentation mechanism. (4) The concentration of sugar: The optimum is about 5 per cent. CO<sub>2</sub> production by *B. licheniformis* is influenced similarly, but in this case the optimum initial reaction of the medium is around pH 8 to 9 and the factors of (3) have little effect.

A description is given of a simple culture test in which these organisms produce visible gas, thus differentiating them from other lactic acid bacteria or from spore formers. The media consist of 5 percent glucose in nutrient gelatin or a mixture of four parts milk and one of nutrient agar, with added yeast extract and a plant juice where necessary. The ability to produce visible gas in a citrate nutrient gelatin medium sealed with agar differentiates certain enterococci and lactobacilli from other species of lactic acid bacteria. In the citrate medium supplemented with comparatively low concentrations

of glucose the heterofermentative lactic acid bacteria produce visible gas, but certain strains fail to do so consistently. No evidence was obtained that growing cultures of lactic acid bacteria liberate H. There are 19 references.

**The effect of acidity on the production of diacetyl by betacocci in milk,** G. A. COX (*Jour. Dairy Res.* [London], 14 (1945), No. 1-2, pp. 28-35, illus. 4).—Betacocci isolated from starters, cheese, and ryegrass investigated at pH 5.5 to 4.4 produced diacetyl and later partially or wholly destroyed it. The amount of diacetyl produced by different strains varied considerably, but the capacity to produce it could not be correlated with any properties of the bacteria. The rate of growth was progressively slower the lower the pH, but at least as much diacetyl was eventually formed at low as at high values. The results revealed an alternation in the metabolism of the organisms, the diacetyl-producing power per unit cell increasing with lowering of the pH. The findings enable an explanation of the rapid production of diacetyl in mixed starters of betacocci (*Streptococcus citrovorus* and *S. paracitrovorus*).

**Temperature control in the H. T. S. T. pasteurization process,** J. A. HALL (*Jour. Dairy Res.* [London], 14 (1945), No. 1-2, pp. 1-20, illus. 18).—An investigation has been made into the accuracy and speed of response of temperature-measuring instruments suitable for use in the control of high-temperature short-time pasteurization. Thermocouples used in conjunction with a "D. C. amplifier" recorder system are shown to be markedly superior to both vapor-pressure and mercury-in-steel thermometers. The accuracy of temperature measurement is about  $\pm 0.3^{\circ}\text{F.}$  as against  $\pm 1^{\circ}$ , while the lag constant is about 0.2 sec. as against about 3 sec. Response to small, rapid, and transient changes of temperature is also shown to be greatly improved. The operation of control contacts by the thermocouple recorder was found to be reliable to well within the limits of accuracy of calibration, but the other types showed variations of the order of  $\pm 1^{\circ}$  in addition to the uncertainties of calibration.

**The resazurin and methylene-blue tests as a measure of the keeping quality of milk,** E. B. ANDERSON and G. S. WILSON (*Jour. Dairy Res.* [London], 14 (1945), No. 1-2, pp. 21-27).—Raw milks were examined during four periods equally spaced throughout the year by the resazurin test and two modifications, the modified methylene-blue test, and a keeping quality test based on taste and alcohol precipitation. From results with 2,588 samples, it is concluded that the data recorded "all go to show that the best indirect index of the K[ee]ping Q[uality] of raw milk is afforded by the methylene-blue test as carried out by the method officially laid down by the Ministry of Health. On the other hand, if time is an overruling consideration, then a slightly less accurate estimate of the K. Q. of raw milk is afforded by the 1-hr. resazurin test."

**The effect of feeding cod-liver oil on the "oxidized" and "goaty" flavors and vitamin C in milk,** E. S. GUTHRIE. (Cornell Univ.). (*Jour. Dairy Sci.*, 29 (1946), No. 6, pp. 349-358, illus. 8).—Feeding cod-liver oil to four cows whose milk was previously free from off-flavors resulted in a loss in the fresh milk of the characteristic flavors of new milk. The milks became oily, but did not have the distinctive cod-liver oil flavor. On standing, a goaty flavor appeared in the milks of three of the cows, and an oxidized flavor in two. In a second experiment with six cows, the milks of two did not acquire an oxidized flavor (with only slight exceptions). The milks of the remainder became oxidized, apparently as the result of administering cod-liver oil either in the feed or by drenching. During a period of 41 days of drenching, the first milk from cow 1 showed a slightly oily flavor, not typically fishy, but later, a very

strong oxidized flavor developed which was of the fishy order. The goaty flavor appeared in this experiment only once and lasted from November 25 to December 4 in the milk of one cow. The vitamin C was below average when the milk was goaty in this experiment, whereas during the first year this flavor was noticeable when the vitamin C was present in abundance.

The results of deaeration on the oxygen, vitamin C, and the oxidized flavors of milk, E. S. GUTHRIE. (Cornell Univ.). (*Jour. Dairy Sci.*, 29 (1946), No. 6, pp. 359-369).—An intermittent deaerator was used in a series of experiments that extended through 3 periods in 3 yr., or a total of 57 weeks. The vitamin C in the milk in these series of analyses dropped from 17.9 mg. per liter in the fresh milk to 16.42 mg. per liter in the deaerated milk at the end of 7 days, and to 7.68 mg. per liter in the undeaerated milk during the same period. The flavor of the milk that was deaerated in the unit was "excellent" when fresh. At the end of 7 days the deaerated milk was "good," whereas the undeaerated milk was "poor" due to the oxidized flavors.

Data obtained during the first 30 months' operation by largely unskilled operators of a continuous deaerator are also reported. Out of 362 analyses on as many days, 49 samples contained no oxygen and many others were near that point. The average of 250 analyses of fresh milk was 17.19 mg. of vitamin C per liter. The "in-bottom filled," the "commercially filled," and the "air reincorporated" samples of 7-day-old milk averaged 15.26, 13.03, and 6.08 mg. of vitamin C per liter, respectively. The flavor of the fresh milk, in general, was excellent, and at the age of 7 days the in-bottom filled, the commercially filled, and the air reincorporated milks were good, fair, and poor, respectively.

"The deaerators used in this study were constructed to take the oxygen out of milk in order to prevent the development of the oxidized flavors. The opinions of several reputable judges of milk show that they accomplished the purpose for which they were made. An added advantage of importance is the preservation of substantial amounts of vitamin C."

Nutritional studies on milk fat, I, II. (Univ. Calif.). (*Jour. Nutr.*, 30 (1945), No. 3, pp. 169-181, illus. 3).—Two papers are presented.

I. *The growth of young rats fed milk and certain synthetic glycerides as supplements to a fat-free diet*, J. L. Henderson, E. L. Jack, S. Lepkovsky, and D. F. Reid (pp. 169-173).—A fat-free diet is described in which all the components were pure compounds with the exception of casein extracted with alcohol and ether. This diet gave satisfactory growth when fed to young rats. Supplementing diets contained fat 20 percent, casein 30, glucose 46, and salt mixture 4 percent, and the same vitamin supplements as the fat-free diet. The fats used were trilaurin, triolein, trilaurin and triolein 1 : 1, and milk fat.

The rats on the milk fat diet and on the triolein diet grew faster than those on the other diets. No significant difference between the two diets with respect to growth was noted. Trilaurin, when fed at the level of 20 percent, enabled the rats to grow at about the same rate or slightly slower than the rats on a fat-free diet. When 10 percent each of trilaurin and triolein were fed, the growth of the rats was intermediate between those receiving trilaurin and those receiving triolein.

II. *The growth of young rats fed glyceride fractions separated from milk fat*, E. L. Jack, J. L. Henderson, D. F. Reid, and S. Lepkovsky (pp. 175-181).—Five glyceride fractions separated from milk fat by precipitation from a solvent were fed to weanling rats. The gains in weight placed the

fractions in three groups. The  $-53^{\circ}$  filtrate was superior to all other diets containing solvent-treated fat; the  $-7^{\circ}$  precipitate and the fat-free were the poorest; the others formed an intermediate group. The diet containing natural milk fat which had not been solvent-treated gave greater growth than any other diet. Diets containing the solvent-treated milk fats (natural, synthetic, and composite) fell in the intermediate group with no significant difference between them. The fatty acid composition of the fats suggested that either the oleic acid content or the total unsaturation might be a factor contributing to differences in growth.

**Experiments on the packing and storage of butter.**—V. The effect of temperature-level of storage on the keeping quality, C. R. BARNICOAT (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 4, Sect. A, pp. 343-348, illus. 2).—Continuing this series (E. S. R., 80, p. 678), the use was studied of temperatures higher and lower than the  $14^{\circ}$  F. used for overseas transport of the meat with which it is usually shipped. At temperatures between  $14^{\circ}$  and  $60^{\circ}$ , the average rate of deterioration of well-made "sweet cream" butter, as measured by decrease in grade score for flavor, was directly related to both time and temperature. The average rate of loss in grade score increased by approximately 0.15 points per week for each  $10^{\circ}$  rise in temperature above  $14^{\circ}$ . Some advantage was obtained by storing butter at  $-5^{\circ}$  instead of  $14^{\circ}$ , but it was so slight that it "would hardly seem to warrant the extra expense involved."

**Some experiments on the use of parchment and Pliofilm for the wrapping of butter in Pinus radiata boxes,** F. H. McDOWALL (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 4, Sect. A, pp. 303-308).—Attempts in New Zealand to utilize the Monterey pine (*P. radiata*) for boxes for export butter revealed a strong timber taint within 10 days in butter wrapped in parchment paper and packed in boxes made from this wood. Use of an aluminum foil sandwiched between parchment sheets prevented development of both primrose color on the surface and of timber taint in the butter, over a period of up to 2 yr., except at joints in the foil wrapping. Sealing of butter in an envelope made from Pliofilm, quality NIV140 or NOV140, prevented development of primrose color over a storage period of 2 yr., but timber taint appeared on the surface after 6 months' storage and was very strong after 2 yr. Treatment of the *P. radiata* shooks with Pliowax before assembly of the box did not prevent timber taint when parchment wrappers were used, but limited it to negligible proportions when a Pliofilm wrap was used with the treated box. Tensitized Pliofilm was not satisfactory with the untreated box with or without parchment.

**A study of the balance of certain milk nutrients in the making of Cheddar, Cheshire, and Stilton cheeses, and of their fate during the ripening of the cheeses,** D. V. DEARDEN, K. M. HENRY, J. HOUSTON, S. K. KON, and S. Y. THOMPSON (*Jour. Dairy Res.* [London], 14 (1945), No. 1-2, pp. 100-116, illus. 3).—A study is reported of the recovery in Cheshire, Cheddar, and Stilton cheese of what are termed the "minor" constituents of summer and winter milk, especially the content of the vitamins and certain minerals. Some 80 percent of vitamin A and carotene, 15 percent of vitamin B<sub>1</sub>, and 25 percent of riboflavin originally present in milk were recovered in the green cheese and persisted throughout ripening. Vitamin C disappeared progressively during cheese making and was absent from the cheeses. Vitamin B<sub>1</sub> and especially riboflavin were recovered in cheese in larger proportions than would be expected from the partition of water between curd and whey,

indicating that they were partly present in milk in combination with the coagulable solids.

The concentrations of the various vitamins in milk and in the ripe cheeses were, respectively, for the winter experiment: Vitamin A 15 International Units per gram of fat and 13 I. U./gm. fat; carotenoids, 1.8  $\mu\text{g.}/\text{gm.}$  fat and 2.0  $\mu\text{g.}/\text{gm.}$  fat; vitamin B<sub>1</sub> 33.5  $\mu\text{g.}/100$  gm. and 53 (Cheddar), 44 (Cheshire), and 80 (Stilton)  $\mu\text{g.}/100$  gm.; riboflavin 84  $\mu\text{g.}/100$  gm. and 300 (Cheddar), 260 (Cheshire), and 240 (Stilton)  $\mu\text{g.}/100$  gm. For the summer experiment the values were: Vitamin A 28 I. U./gm. fat and 25 I. U./gm. fat; c rotenoids 10  $\mu\text{g.}/\text{gm.}$  fat and 9-10  $\mu\text{g.}/\text{gm.}$  fat; vitamin B<sub>1</sub> 42  $\mu\text{g.}/100$  gm. and 55 (Cheddar), 48 (Cheshire), and 75 (Stilton)  $\mu\text{g.}/100$  gm.; riboflavin 128  $\mu\text{g.}/100$  gm. and 330 (Cheddar), 330 (Cheshire), and 360 (Stilton)  $\mu\text{g.}/100$  gm.

There was no difference between the three types of cheese made in winter in biological value or true digestibility of the proteins, for which values of 72 and 98, respectively, were obtained at an 8-percent level of protein intake.

Diets were blended from dried Cheshire, Cheddar, or Stilton cheese and from dried whey to approximate the composition of a sample of dried milk. These diets, when supplemented with iron, copper, and manganese and given as an exclusive diet, produced growth in rats as good as that obtained with the mineralized milk itself.

[Bacteriophage studies with cheese] (*Jour. Dairy Res. [London]*, 14 (1945), No. 1-2, pp. 64-100, illus. 5).—These studies include Bacteriophage Infection in Cheese Manufacture, by H. R. Whitehead and G. J. E. Hunter (pp. 64-80); and Observations on Cheese Starters With Reference to Bacteriophage and the Phage-Organism Relationships of Strains Isolated (pp. 81-93), and The Heat Resistance of the Bacteriophages of Cheese Starter, With Observations on the Estimation of Phage Concentration (pp. 93-100), both by A. A. Nichols and J. Z. Wolf.

Reactions and properties of annatto as a cheese colour, II, C. R. BARNICOAT (*Jour. Dairy Res. [London]*, 14 (1945), No. 1-2, pp. 59-63).—Further work on the standardization of annatto for cheese coloring supports the author's earlier conclusions (E. S. R., 77, p. 390) that the coloring power of annatto extracts in cheese can be estimated by their tinctorial power in dilute alkaline solution. A simple tintometer of the "Limitester" type was found to be suitable for this work, a standard orange disk, or Lovibond yellow and orange glasses, being used as the standard.

[Research on dried milk] (*Jour. Dairy Res. [London]*, 14 (1945), No. 1-2, pp. 116-194, illus. 13).—The following papers are included: The Effect of Temperature of Pre-heating, of Clarification, and of Bacteriological Quality of the Raw Milk on the Keeping Properties of Whole-Milk Powder Dried by the Kestner Spray Process, by A. T. R. Mattick, E. R. Hiscox, E. L. Crossley, C. H. Lea, J. D. Findlay, J. A. B. Smith, S. Y. Thompson, and S. K. Kon (pp. 116-159); Spray-Dried Milk Powder—Commercial Observations Over Two Years of the Effect of High-Temperature Pre-heating, by E. L. Crossley (pp. 160-164); Experiments on the Use of Antioxidants in Spray-Dried Whole-Milk Powder, by J. D. Findlay, J. A. B. Smith, and C. H. Lea (pp. 165-175); The Effect of the Method of Reconstitution and of the Temperature of Incubation on the Plate Count of Spray-Dried Milk Powder, by E. R. Hiscox (pp. 175-183); and The Technique of the Bacteriological Examination of Dried Milks, by C. Higginbottom (pp. 184-194).

Condensed milk and milk powder, O. F. HUNZIKER (*La Grange, Ill.: Author, 1946, 6. ed., rewritten, pp. 502+, illus. 128*).—This edition (F. S. R., 73, p. 676) has been condensed and rewritten.

Relation of the temperature of separation and the heat treatment given the skim milk to the keeping quality of spray-dried ice cream mix, H. PYENSON and P. H. TRACY. (Univ. Ill.). (*Jour. Dairy Sci.*, 29 (1946), No. 6, pp. 371-379).—There was a tendency toward more rapid oxygen absorption, more carbon dioxide evolved, and more oxidized flavor development in mixes that had the condensed skim milk forewarmed to 150° F. for 20 min. than in those mixes that had the condensed skim milk forewarmed at 180° for 5 min. There seemed to be no significant differences in oxidized flavor development when the mixes were prepared from concentrated skim milk made from skim milk separated at 55° or 130°. Whether the fat used was in the form of cream, butter, or butter oil was not a factor influencing the keeping quality of the dried ice cream mix. All the batches which contained butter oil, butter, or cream became oxidized if made with skim milk forewarmed at 150° for 20 min. After 1 yr., dried mixes made from skim milk forewarmed at 180° for 5 min. had not developed an oxidized flavor and were still highly palatable.

"High forewarming temperature on the skim milk before condensing is beneficial in prolonging the keeping qualities of dried ice cream mixes and the retardation of oxidized flavor development."

Technical literature [on ice cream] for 1945, A. LEIGHTON. (U. S. D. A.). (*Ice Cream Rev.*, 29 (1946), No. 11, pp. 41-42, 106-112).—This is a review of the technical literature on ice cream for 1945, with a bibliography of 216 titles.

## VETERINARY MEDICINE

[Miscellaneous papers] (*Cornell Vet.*, 36 (1946), No. 1, pp. 1-16, 51-66, illus. 10).—These papers include Observations on Prolapsed Rectum in Sheep, by J. W. Britton (pp. 1-4) (Univ. Calif.); Urinary Calculi Associated With Vitamin A. Deficiency in the Fox, by C. F. Bassett, L. E. Harris, S. E. Smith, and E. D. Yeoman (pp. 5-16) (Cornell Univ. et al.); and The Lymphatic Circulation of the Hind Limbs of the Horse, by I. Rossoff (pp. 51-66).

Tolerance of farm animals to feed containing 2,4-dichlorophenoxyacetic acid, J. W. MITCHELL, R. E. HODGSON, and C. F. GAETJENS. (U. S. D. A.). (*Jour. Anim. Sci.*, 5 (1946), No. 2, pp. 226-232, illus. 1).—Sheep and cows grazed pasturage treated with a liberal application of weed killer (2,4-dichlorophenoxyacetic acid and Carbowax mixture). There was no apparent reduction in its palatability. The 2,4-D, consumed either on pasture grass eaten by sheep and cows or in the ration fed to a cow at the rate of 5.5 gm. daily, produced no apparent harmful effects in the health and performance of the animals. Post-mortem examinations revealed no pathological conditions in cows grazing on pasture treated with 2,4-D, nor was this material found to be present in the liver, kidney, or fatty tissues of a cow fed 2,4-D.

By means of a biological method of assay, the presence of 2,4-D was demonstrated in the blood serum of a cow fed 5.5 gm. of this material daily for 106 days. Results of these tests indicate that the 2,4-D probably occurred as a water-soluble salt. The 2,4-D was not found to be secreted into the milk, nor was it found in the blood serum of a calf fed milk from the cow that received it in her ration.

It is concluded from these data that the amount of 2,4-D that might be consumed by cows or sheep from pasturage sprayed with this material to

kill weeds would not be injurious. It is pointed out, however, that these experiments are based on the use of purified 2,4-D together with Carbowax, and that while they indicate that the acid is not toxic the results are not applicable to proprietary formulations that might contain other ingredients.

**Pathology of selenium poisoning.** I. ROSENFELD and O. A. BEATH (*Wyoming Sta. Bul.* 275 (1946), pp. 27, illus. 19).—The material for this report was obtained from 10 range animals showing acute selenium poisoning, 5 range animals showing "alkali disease," and 10 showing the "blind staggers" type of chronic selenosis. Also included is a study of the gross and microscopic pathologic changes of the subacute and blind staggers type of chronic selenium poisoning produced experimentally. Yearling ewes were used as experimental animals, and the selenium was administered by drenching.

Gross and microscopic pathologic findings of acute, subacute, and chronic selenium poisoning are presented. It is stated that each different type of selenium poisoning presented a well-defined pathologic entity. Diagnosis can be made on the basis of the pathologic findings in the liver, lung, kidney, gastrointestinal tract, and spleen. It is erroneous to base the diagnosis on the changes observed in a single organ since selenium enters in the blood very rapidly and produces injury in all the organs. The action of selenium appears to be similar to that of arsenic. The primary injury appeared to be cellular due to the capillary damage.

In acute selenium poisoning, the outstanding pathologic changes were necrosis and hemorrhages due to capillary damage. In subacute poisoning, various degrees of repair and early fibrosis were observed in all the organs. Chronic selenosis was subdivided into two groups—blind staggers and alkali disease. In blind staggers on a low grade, chronic injury, an acute exacerbation was superimposed. The tissues showed chronic degenerative changes with acute toxic reaction. In alkali disease, chronic, toxic degenerative changes were observed in all organs, and acute irritation was absent.

The relations of the pathologic changes to the functional disorders are discussed.

**The elimination and distribution of selenium in the tissues in experimental selenium poisoning.** I. ROSENFELD and O. A. BEATH. (*Wyo. Expt. Sta.*). (*Jour. Nutr.*, 30 (1945), No. 6, pp. 443-449).—Sheep were fed graded doses of selenium for a limited period (44 days) or until death. Analyses of urinary excretion of selenium showed that prior to death from selenium poisoning, the animals eliminated smaller quantities in the urine, due to kidney damage, and stored larger amounts in all tissues.

Those animals fed selenium for a limited period continued to excrete selenium gradually in the urine for a considerable time after the mineral was no longer incorporated in the diet. Not until 50 days later did the urine show only traces or was free of selenium.

The storage of selenium in the body varied with the amount administered. The liver and kidney, in all groups tested, contained the greatest amount, while the brain and muscle contained the least. No selenium was found in the fat.

Small amounts of selenium were present in all tissues 61 and 64 days after the last dose had been given. The authors consider the amount present at this time to be insufficient to cause any harmful effects if used in the human diet.

**The relationship between diet and the mechanisms for defense against bacterial infections in rats.** L. J. BERRY, J. DAVIS, and T. D. SPIES (*Jour. Lab. and Clin. Med.*, 30 (1945), No. 8, pp. 684-694, illus. 2).—"These observa-

tions support the working hypothesis that resistance to certain bacterial infections may be depressed by inadequate nutrition and are in agreement with work previously done with patients. Malnutrition is thus shown to be a factor in susceptibility to infection, but this is not necessarily true in every type of infection."

**Changes of the blood constituents in diseases of ruminants, J. W. BRITTON.** (Univ. Calif.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 25-30).—Normal values for hemoglobin cell volume, sugar, and nonprotein nitrogen of the blood of 134 sheep under varying conditions of management were ascertained. The biochemical changes accompanying various digestive disorders in sheep and cattle are also enumerated.

**Dissociation in *Brucella abortus*: A demonstration of the rôle of inherent and environmental factors in bacterial variation, W. BRAUN.** (Univ. Calif. coop. U. S. D. A.). (*Jour. Bact.*, 51 (1946), No. 3, pp. 327-349, illus. 9).—With the help of single cell isolation the existence of inherent differences between clones of *B. abortus*, strain 19, in regard to dissociation percentages has been demonstrated under standardized environmental conditions. Clones with statistically significant differences in dissociation indices have been systematically selected and have remained stable if stored at low temperatures. These inherent dissociation percentages can be modified by environmental changes, particularly changes which affect growth rates and viability.

The studies on environmental effects suggested that dissociation percentages, as such, are not an inherent characteristic, but rather secondary indicators of primary inherent differences in growth rate and viability between clones. Bacterial dissociation is thus interpreted in terms of the spontaneous appearance of variants (mutants) and their subsequent establishment under the control of the inherent and environmental factors which govern population dynamics.

**What do we know about ketosis (acetonemia) in dairy cattle? J. C. SHAW.** (Univ. Md.). (*Holstein-Friesian World*, 43 (1946), No. 9, pp. 24-25, 113, illus. 3).—An experimental ketosis was produced by reducing the food intake just prior to calving and subsequent thereto and alleviated by an increase in feed consumption, but it is stated that "other cases have been observed where it was difficult to ascribe the ailment to a limited feed intake." No case of ketosis was found in rather extensive experiments in which either the blood plasma carotene or vitamin A was low, and massive doses of vitamin A and thiamine and other B vitamins and intravenous and oral administration of methionine have not been found beneficial. The best treatment found to date is the injection of dextrose directly into the venous blood, supplemented by the feeding of some form of soluble sugar such as molasses or corn sugar. Severe cases may require several injections.

Other findings are presented graphically and discussed.

**What do we know about ketosis in dairy cattle? J. C. SHAW.** (Univ. Md.). (*Guernsey Breeders' Jour.*, 69 (1946), No. 10, pp. 1316-1319, 1362, 1364, illus. 3).—A practical discussion of this disease, including its occurrence, diagnosis, treatment, and prevention.

**The value of vitamin A therapy in cases diagnosed as ketosis in dairy cows, C. E. HAYDEN, M. G. FINCHER, S. J. ROBERTS, W. J. GIBBONS, and A. G. DANKS.** (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 71-84).—This study of 10 cases which seemed to represent some degree of ketosis revealed unsatisfactory responses to vitamin A therapy, although the dosage

was ample and 1 case received 18,500,000 units during the treatment. It is concluded that none of the cases were due to vitamin A deficiency.

A contagious disease of cattle associated with *Leptospira*, F. P. MATHEWS. (Tex. Expt. Sta. and U. S. D. A.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 33, pp. 73-83, illus. 11).—A febrile disease of cattle involving both epizootic and enzootic outbreaks is reported, as encountered on three ranches in Brewster, Presidio, and Jeff Davis Counties in Texas in the late summer and fall of 1942. Four forms of the disease were recognized; first, a slight illness of but a few hours' duration; second, a continuation of the first and followed by noticeable ill effects but eventual recovery; third, an acute fatal form characterized by hemoglobinuria and focal necrosis of the liver; and fourth, a chronic form characterized by parenchymatous and interstitial nephritis and a wide variety of other lesions. The mild forms of the disease were reproduced in seven calves by injection of blood from field cases, and the chronic lesions of the kidneys were reproduced in one out of six guinea pigs. Sheep, goats, and rabbits did not appear to be susceptible.

It is concluded that the pathology of the disease has much in common with that of leptospirosis in dogs. *Leptospira* were demonstrated in the tissues of some, but could not be found in all of the field cases. The serum of six experimental and three field cases did not agglutinate either *L. canicola* or *L. hemorrhagiae* antigens, and *Leptospira* has not been proved to be the cause of this disease.

Penicillin in the treatment of bovine mastitis. F. W. SCHOFIELD (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 3, pp. 63-70; *Fr. abs.*, p. 70).—Penicillin assays of milk drawn at various times after udder infusions indicated that penicillin is very variable in the rate at which it is absorbed from the udder. Infusion results obtained by the author, using different degrees of concentration and periods of inhibition, are tabulated, and "up to the present compare very unfavorably with those quoted by other investigators." The work recorded and discussed is regarded as of a preliminary nature, but the following conclusions are drawn:

"*Streptococcus agalactiae* infection of the bovine udder may be resistant to penicillin when given in a unitage and frequency sufficient to produce a reasonable level of inhibition. (No penicillin-resistant strains have so far been encountered.) Acute mastitis, when due to either *Staphylococcus aureus* or *Corynebacterium pyogenes*, shows moderate clinical improvement only when treated with penicillin unless the treatment is commenced immediately after the infection is established. With immediate treatment, the results may be highly satisfactory. The best results are obtained when an inhibitory level of penicillin is maintained for 3 consecutive days. There is evidence to show that *Streptococcus agalactiae* is more resistant to penicillin in acute outbreaks of mastitis than when the organism is present in the udder unaccompanied by any clinical manifestations of disease."

Penicillin in peanut oil with 3 per cent beeswax: Local use in bovine staphylococcal mastitis, J. W. WALKER (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 413-421, illus. 5).—Several experiments are reported with injections of peanut oil and beeswax and penicillin in various concentrations. These preparations were found to be relatively nonirritating to the bovine udder and effective against either streptococcus or staphylococcus infections.

"Though penicillin is not as effective against staphylococci as it is against streptococci, it is apparently more effective than any other known therapeutic agent against staphylococci. At present, it is impossible to

state the optimum dosage, but a rather high level of dosage seems indicated. The testing of a specific infection for sensitivity to penicillin is desirable in resistant cases."

The concentration of penicillin in fore milk following intramammary infusion for the treatment of mastitis—preliminary report, W. G. STEVENSON (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 3, pp. 82-83; *Fr. abs.*, p. 83).—Twelve hr. after the infusion into all four quarters of 25,000 Oxford units of sodium penicillin, 14 Oxford units were found to persist in the fore milk. It is concluded that penicillin is not rapidly destroyed in the bovine mammary gland, and suggested that a longer interval between infusions may be satisfactory for cows that are dry or giving only a few pounds of milk daily.

Rinderpest, I-XVI (*Amer. Jour. Vet. Res.*, 7 (1946), No. 23, pp. 133-237, *illus.* 8).—This series of 16 papers, together with a foreword (pp. 133-134), deals with a project carried on during World War II on an island in the lower St. Lawrence River with a joint United States-Canadian scientific staff and Canadian army service personnel. This project included two problems: "The first was to prepare a tissue vaccine according to methods previously developed, in order to provide rapidly the means of surrounding an epizootic, should it occur, with a ring of immunized animals. The success of this procedure is indicated in the third paper in the following series. The second problem was to investigate the possibility of developing an efficient vaccine which could be produced more economically and without requiring the use of large numbers of animals. Subsequent papers in the series detail the manner in which the virus was adapted to embryonated hen's eggs and attenuated for cattle with retention of high antigenic properties. The final papers in the series indicate the methods used in the large-scale production and testing of the avianized vaccine."

The several papers are as follows: I, The Cultivation of Rinderpest Virus in the Developing Hen's Egg, by R. E. Shope, H. J. Griffiths, and D. L. Jenkins (pp. 135-141); II, Certain Immunity Reactions, by R. V. L. Walker, J. A. Baker, and D. L. Jenkins (pp. 142-144); III, Immunization Experiments With Inactivated Bovine Tissue Vaccines, by R. V. L. Walker, H. J. Griffiths, R. E. Shope, F. D. Maurer, and D. L. Jenkins (pp. 145-151); IV, Infection of the Embryos and the Fluids of Developing Hens' Eggs, by R. E. Shope, F. D. Maurer, D. L. Jenkins, H. J. Griffiths, and J. A. Baker (pp. 152-163); V, Attempts to Prepare an Effective Rinderpest Vaccine From Inactivated Egg-Cultivated Virus, by F. D. Maurer, R. V. L. Walker, R. E. Shope, H. J. Griffiths, and D. L. Jenkins (pp. 164-169); VI, The Persistence of Virus in Chicks Hatched From Infected Eggs, by R. E. Shope and H. J. Griffiths (pp. 170-173); VII, The Attenuation of Rinderpest Virus for Cattle by Cultivation in Embryonating Eggs, by D. L. Jenkins and R. E. Shope (pp. 174-178); VIII, Rinderpest Infection in Rabbits, by J. A. Baker (pp. 179-182); IX, Neutralization Tests in Rabbits as a Measure of the Immune Responses in Calves to Vaccination Against Rinderpest, by D. L. Jenkins and R. V. L. Walker (pp. 183-188); X, The Response of Guinea Pigs to the Virus of Rinderpest, by J. A. Baker, J. Terrence, and A. S. Greig (pp. 189-192); XI, The Survival of Rinderpest Virus in Various Mediums, by F. D. Maurer (pp. 193-195); XII, The Successful Use of Young Chicks to Measure the Concentration of Rinderpest Virus Propagated in Eggs, by J. A. Baker and A. S. Greig (pp. 196-198); XIII, The Production of Rinderpest Vaccine From an Attenuated Strain of Virus, by M. W. Hale and R. V. L. Walker (pp. 199-211); XIV, Immunization Experiments With Attenuated

Rinderpest Vaccine Including Some Observations on the Keeping Qualities and Potency Tests, by M. W. Hale, R. V. L. Walker, F. D. Maurer, J. A. Baker, and D. L. Jenkins (pp. 212-221); XV, Morphological Changes in the Blood of Young Cattle During Rinderpest and After Vaccination With Attenuated Virus Vaccine, by T. O. Robey and M. W. Hale (pp. 222-227); and XVI, Complement Fixation Test for Rinderpest, by H. K. Cooper (pp. 228-237).

Some observations on the blood leucocyte picture in bovines during reaction to the intradermal tuberculin test, G. H. ARTHUR (*Vet. Jour.*, 102 (1946), No. 6, pp. 147-157, illus. 1).—Total and differential leucocyte counts were made before, and at intervals during, the reaction to the double intradermal comparative tuberculin test in a group of 10 heifers, and in 5 nonreacting animals. The initial and second tuberculin injections were followed by marked increases in the total leucocyte counts and by a significant narrowing of the lymphocytic-neutrophilic ratio in the reacting group, but no such changes occurred in the nonreacting group. In one reacting animal investigated at 2-hr. intervals during the tuberculin test the maximum blood change occurred 6 hr. after the second injection of tuberculin.

Eosinophilia did not occur except in the 1 animal studied individually, where the count was 29 percent at 12 hr. after the second tuberculin injection. Neutrophilia was accompanied by an increase in skin measurement, but no proportional relationship was found to exist between them. The greatest change in the blood picture occurred later than the maximum skin reaction. The leucocytic changes in animals which had been reacting to the tuberculin test for 1½ yr. were similar to those which occurred in reactors of a few months' duration.

Koboltmangelens betydning som sykdomsarsak hos storfe og sau belyst ved terapeutiske forsok (The therapeutic effect of small doses of cobalt in combating deficiency diseases in cattle and sheep in Norway), F. ENDER (*Norsk Vet. Tidsskr.*, 58 (1946), No. 4, pp. 118-143; *Eng. abs.*, pp. 141-142).—The therapeutic importance of supplying cobalt to affected animals is shown by results of experiments which embraced the treatment of more than 1,000 cattle and sheep. On the average, treatment with cobalt alone led to recovery in 90 percent of the cases reported. The rapid and successful effect of cobalt medication was striking. It is concluded that from an etiological standpoint lack of cobalt must be assigned greater importance than lack of copper in the deficiency diseases in livestock.

Studies on enzootic staphylococcal infection in lambs associated with tick-bite.—II, The bacteriology of the disease, A. MCDIARMID (*Vet. Rec.*, 58 (1946), No. 22, pp. 243-244).—In this continuation of the study (E. S. R. 95, p. 246), 19 strains of staphylococci were isolated from 14 lambs affected with pyemia. Thirteen were classified as virulent strains of *Staphylococcus aureus*, 2 were deficient in a toxin, and 4 were avirulent and did not produce a or  $\beta$  toxins. These strains could be distinguished by a variety of tests. The view is expressed that the strains deficient in one or both toxins were not another species of *Staphylococcus* but represented strains that had lost some of their virulent characters as a result of subcultivation.

Experiments on the pathogenicity of hookworm (*Bunostomum trigonocephalum*) infections in lambs fed an adequate diet, J. T. LUCKER and E. M. NEUMAYER. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 23, pp. 101-122, illus. 5).—Heavy experimental infections with *B. trigonocephalum* were produced in eight male lambs of mixed breeding and from 4 to 4.5 mo. old when the first experiment began. This hookworm was found to be

pathogenic, causing the lambs to become anemic and depressing their rate of growth. Lighter infections were less serious, with temporary anemia and interference with growth.

When 5,000 or 50,000 larvae were given orally, far lighter infections resulted than when these numbers of larvae were applied to the skin. However, exposure of lambs to percutaneous infection by extremely large numbers (560,000 to 580,000) of larvae apparently provoked processes, of undetermined nature, which were highly effective in inhibiting the development of adult worms. It is concluded that neither acquired nor age resistance can be regarded as adequately explaining the relatively light infections produced by these large larval administrations.

Differential counts showed that all significantly infected lambs had a degree of eosinophilia related directly to the magnitude of their hookworm burdens. Such infections also tended to cause slight monocytosis and basophilia. In each experiment, the degree of anemia observed in significantly infected lambs tended to be directly related to the magnitude of the per-gram counts of hookworm eggs passing in their feces and to the magnitude of their hookworm burdens. The anemia of the heavily infected lambs was normocytic, but tended to be hypochromic.

Ten per cent cunic for controlling gastrointestinal helminthiasis in sheep, J. H. WHITLOCK. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 47-50, *illus.* 1).—This report establishes the fact that 10 percent cunic (copper sulfate and Black Leaf 40) is no more toxic and much handier to give than 1 to 2 percent drenches. Control of helminthiasis was good in those flocks that were given phenothiazine or tetrachloroethylene at the start of the season and subsequently dosed with 10 percent cunic.

A preliminary report on use of lead arsenate for removal of the sheep tapeworm, *Moniezia expansa*, J. W. WARD and J. W. SCALES. (Miss. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 425-426).—Treatment of 18 lambs with from 0.5 to 1 gm. each of lead arsenate in a gelatin capsule checked their diarrhea and each animal expelled from 10 to 160 chains of segments of *M. expansa*. Two animals were re-treated 5 weeks later. The results "indicate that lead arsenate is useful in the control of tapeworms in lambs in that clinical symptoms subsided after treatment and the animals made an uneventful recovery."

Observations on the prophylactic and curative value of sulfaguanidine in swine coccidiosis, J. E. ALICATA and E. L. WILLETT. (Hawaii Expt. Sta.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 23, pp. 94-100, *illus.* 3).—In the course of six experiments, each of 18 young pigs were experimentally infected with 20 to 30 million oocysts from mixed cultures of *Eimeria deblicieki* and *E. scabra*. Five of the pigs were used to determine the prophylactic value of sulfaguanidine, 5 to determine its curative value, and 8 as controls. The treated pigs received the drug, mixed with feed, at the rate of 1 gm. per 10 lb. of body weight. Prophylactic treatment started 2 days before experimental coccidial infection and continued on the day of infection and for 7 or 10 more days. In the curative treatment, the drug was administered for 3 days starting with the second day of oocyst discharge.

All the pigs which received prophylactic treatment remained normal and made satisfactory body gains. Untreated control pigs developed diarrhea, lost appetite, and made either little or no body gain. It is concluded that "prophylactic use of sulfaguanidine inhibits the life cycle of [these] species of swine coccidia and prevents symptoms associated with the disease. When given as a cure, the drug brings about a reduction in oocyst output, thus pre-

venting the spread of the disease, and may also bring about a quicker termination of the diarrheal condition."

**Studies on the validity of swine erysipelas culture-vaccines, L. VAN ES, J. F. OLNEY, and I. C. BLORE** (*Nebraska Sta. Res. Bul. 145 (1946), pp. 30, illus. 34*).—A series of experiments undertaken by the station to determine what influences might be accountable for the production of inferior vaccination materials is reported. The publication deals with modes of procedure, analyses of the average validity. H-ion concentration, growth capacity, and approximate incubation periods, with notes and comments and a series of graphs.

It was found that the average validity of 10 vaccine cultures prepared in accordance with standard methods was acceptable, even if one of the component culture vaccines was valid only in the first incubation period and two others had become substandard in the third period. The presence of 0.5 percent glucose in the culture broth exercised a decidedly depressing influence on the average validity of culture vaccines grown therein. Culture vaccines prepared with beef heart broth treated with yeast prior to inoculation were of an acceptable validity only in the first period. Culture vaccines grown in liver broth failed to show acceptable validity.

The culture vaccine grown in broth furnished by a concern which at the time often failed to produce valid vaccine material showed a maximum validity only in the first period and proved to be nonacceptable in the other two. On the other hand, the culture vaccine prepared by a producer who had constantly succeeded in the production of acceptable materials presented a high degree of validity throughout. "There is warrant for the belief that the problem connected with subvalid culture vaccines can be solved only in the laboratories concerned, rather than by such attempts as described in this publication." Differences were observed in the validity of culture vaccines grown in broth, each of which was prepared with a different brand of peptone. In one of the two culture vaccines, the validity was high in the first period, barely acceptable in the second, and of substandard quality in the third. In the case of the culture vaccine grown in broth in which the other specimen of peptone was a part, an acceptable validity was attained in each of the three periods. In a parallel broth prepared without peptone, the culture grown therein was valid in the first and second periods but was markedly subvalid in the third. The value of peptone in the maintenance of bacterial longevity was demonstrated, and this may suggest that a reduction in the peptone contents of the culture broth may occasionally impair culture vaccine validity.

Room temperature incubation and storage did not prove to be harmful to culture vaccine validity, and apparently incubation at 37.5° C. in the preparation of culture vaccines may not be a necessity. The nature of glassware used in storage, the length of time after pigeon passage, agitation, the fat content of beef hearts, and a degree of putrefaction did not appear to influence culture vaccine validity.

**Orchitis in swine due to *Brucella suis*, H. C. H. KERNKAMP, M. H. ROEPKE, and D. E. JASPER.** (*Minn. Expt. Sta. and U. S. D. A.*). (*Jour. Amer. Vet. Med. Assoc., 108 (1946), No. 829, pp. 215-221, illus. 3*).—Several cases are reported as "the result of observations and studies on what might be described as a fulminating enzootic of brucellosis in a herd of swine. It deals with the incidence of the disease among the males in the herd especially, and with the clinical, pathologic, and bacteriologic findings thereof."

Changes in the equine larynx associated with laryngeal hemiplegia, C. R. COLE. (Ohio State Univ.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 23, pp. 69-77, illus. 10).—The factors considered in this study of 174 equine larynges were the changes in the muscles, the nerves supplying the muscles, and the cartilages of the larynx.

Penicillin dosage and blood levels for horses, E. R. DOLL and W. W. DIMOCK. (Ky. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 103 (1946), No. 829, pp. 209-214).—Data were obtained on the in vitro sensitivity to penicillin of a number of strains of organisms causing infections in horses. Blood-level responses from intramuscular administration of penicillin in saline solution were correlated with organism sensitivity in regard to therapeutic use of the drug. For *Streptococcus equi* infections (strangles) in horses, it appeared that the minimum dosage should be 300 units per pound of body weight every 3 hr. For infections caused by other streptococci, this dosage appeared adequate for only 2½ hr., while 500 units per pound probably sufficed for 3 hr. except in very young foals, in which 500 units per pound maintained a satisfactory blood level for only 2 hr. The resistance of *Shigella equirulis* to penicillin was high—2 to 4 units per cubic centimeter, and hourly dosage of 1,000 to 2,000 units per pound would not maintain completely inhibitive blood levels. The resistance of *Corynebacterium equi* was so great (8 to 10 or more units per cubic centimeter) that dosage for maintaining effective blood levels appeared impractical.

Precipitin-production in chickens.—II, Studies on the in vitro rise of the interfacial titers and the formation of precipitins, H. R. WOLFE and E. DILKS. (Univ. Wis.). (*Jour. Immunol.*, 52 (1946), No. 4, pp. 331-341).—Adult male chickens of various breeds were injected intravenously with serum proteins from cattle, buffalo, sheep, horse, goat, dog, or man. A detailed description is given of the in vitro use in the interfacial precipitative titer, and the relative value of the antisera produced is discussed.

Immunization against a lymphoid tumor of the chicken.—III, Attenuation by heat, drying, and chemicals, C. OLSON, JR. (Mass. Expt. Sta.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 41-47).—Continuing this series (E. S. R., 94, p. 809), the growth capacity of the lymphoid tumor was attenuated by heat. When the growth capacity was destroyed, the immunizing ability was likewise lost. The tumor was relatively resistant to heat and not completely inactivated by exposure to 70° C. for 15 min. Dried tumor, necrotic tumor, and tumor pulp preparations treated with phenol or formaldehyde were inactive and did not induce resistance.

The toxicity of sodium chloride for fowls, J. D. BLAXLAND (*Vet. Jour.*, 102 (1946), No. 6, pp. 157-173, illus. 4).—In these experiments, although approximately 4 gm. of sodium chloride per kilogram of body weight were fatal to mature fowls when placed as a single dose directly into the crop, the same dose mixed into the food was not highly toxic in the case of four mature cockerels, housed individually, and no mortality occurred. No mortality could be attributed to sodium chloride poisoning when mash containing 5, 10, 15, and 20 percent, respectively, of salt were fed to mature fowls over a period of 4 weeks. When single feeds of mash containing 15, 20, and 30 percent, respectively, of sodium chloride were fed to groups of adult fowls, as far as possible under field conditions, a low mortality occurred with the higher concentrations. There was also no excessive mortality in growing chickens when mash containing 5, 10, and 15 percent, respectively, of sodium chloride were fed for 14 days. In the case of baby chicks, however, where sodium chloride was fed in the mash in a concentration of 10

percent, a 50 percent mortality occurred within 3 days and after 2 weeks there had been an 80 percent mortality. With a 5 percent concentration there was a 30 percent mortality in 3 days. When sodium chloride in solution, even as a normal saline (0.9 percent), was given instead of drinking water, a 100-percent mortality occurred within 5 days.

The effect of some aryl arsonic acids on experimental coccidiosis infection in chickens, N. F. MOREHOUSE and O. J. MAYFIELD (*Jour. Parasitol.*, 32 (1946), No. 1, pp. 20-24).—When given as a preventive in the drinking water of chickens, the two aryl arsonic acids 4-hydroxy phenylarsonic acid and 3-nitro 4-hydroxy phenylarsonic acid and their sodium salts were effective in reducing hemorrhage and mortality from the coccidium *Eimeria tenella*. 4-Hydroxy phenylarsonic acid was found to have some effects against the intestinal species of coccidia *E. acervulina*. Nontoxic doses were not effective. While 3-nitro 4-hydroxy phenylarsonic acid prevented mortality from *E. tenella* infection, the birds developed a considerable immunity toward subsequent infection with this species.

The incidence of erythroleucosis following inoculation by various routes, A. B. WICKWARE (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 3, pp. 74-81).—In an attempt to solve the problem of the natural means of transmission, 163 chickens were inoculated by various routes. The results were corroborative in some degree of those obtained by other workers, but "also indicate the successful transmission of erythroleucosis by the instillation into the nasal cavities of heparinized whole blood and by the intravenous inoculation of salinized nasal washing of infected fowls." In 44 chicks hatched from apparently recovered pullets, there was no indication of the virus being egg-borne. Infection did not occur in any of the direct and indirect contact trials with birds of various breeds.

The transmission of lymphomatosis in the fowl, N. R. BREWER and B. BROWNSTEIN (*Amer. Jour. Vet. Res.*, 7 (1946), No. 23, pp. 123-128, illus. 2).—Tissue from a lymphomatous liver and spleen from a typical field case of lymphomatosis (uncomplicated by blood dyscrasia) was transmitted into White Leghorn chicks through 15 passages. In the fifteenth passage, 59 per cent of the birds died with lymphomatous lesions before they reached 100 days of age. Fifty per cent of these inoculated chicks were dead with lymphomatous lesions within 24 days. Chicks brooded with sibs inoculated with the infective tissue developed a significantly higher incidence of lymphomatosis than did controls. Chicks fed the infective tissue developed a significantly higher incidence of lymphomas than did the control sibs from the same hatches.

Newcastle disease and fowl plague investigations in the war research program, C. A. BRANDLY, H. E. MOSES, E. L. JUNGHER, E. E. JONES, and E. E. TYZZER (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 869-871).—This is a preliminary report on the facilities and procedures in this project and a summary of some of its more important results.

Perosis caused by feeding high levels of thiouracil, G. M. BRIGGS and R. J. LILLIE. (Md. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 61 (1946), No. 4, pp. 430-432).—Perosis, as characterized by an enlargement of the tibia-metatarsal joint and by a thickening and bending of the metatarsal, was obtained in young chicks by the feeding of relatively high levels of thiouracil (0.5 per cent) over a period of 5 weeks. The disorder was not prevented by the addition of manganese, choline, nicotinic acid, biotin, or riboflavin to the thiouracil-containing ration, but it is suggested that thyro-

xine may in some manner aid in the prevention of perosis under normal conditions.

**Studies in pullorum disease.**—VIII, The possible relationship of non-specific reactions to the sensitizing influence of ingested proteins, E. W. BOND (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 3, pp. 71-73; *Fr. abs.*, p. 73).—Continuing this series (E. S. R., 94, p. 335), the possibility was investigated of a relationship between a high protein diet and the occurrence of nonspecific agglutinins for *Salmonella pullorum*. Tests using 100 New Hampshire pullets were made with meat meal, milk powder, soybean meal, and fish meal, but no relationship could be determined.

**Sulfamerazine in the treatment of pullorum disease**, G. W. ANDERSON. (S. C. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 427-428).—Following a natural outbreak of pullorum disease in baby chicks in which treatment was not begun until 14 days after the onset of the disease, sulfamerazine was effective in reducing the mortality. It is regarded as being effective in such outbreaks if an early diagnosis is established and treatment is provided promptly.

**Some observations on the control of fowl typhoid infection with sulfa drugs**, D. F. HOLTMAN and G. FISHER. (Univ. Tenn.). (*Jour. Bact.*, 51 (1946), No. 3, p. 401).—An epidemic of fowl typhoid appearing in a flock of 400 week-old battery-raised chicks caused 20 percent mortality within 3 days. At this time the flock was divided into two groups. Group 1 received the usual care, consisting of removal of sick chicks, cleaning, and disinfection of the battery with cresol solution. Group 2 received no such care, but instead was given 0.1 percent sodium sulfathiazole in drinking water for a period of 1 week. At the end of the week, 80 percent of the chicks in group 1 had died. Losses in group 2 had been reduced to 4 percent, with no mortality during the last 3 days of the week.

The chicks in group 2 were taken off sulfa drug treatment and within 5 days the infection reappeared. Drinking water containing 0.1 percent sodium sulfathiazole was again supplied for 1 week, and the epidemic was checked with a 2 percent loss. After a second week without treatment another outbreak of the infection occurred, and the chicks were returned to still another week of sulfa drug treatment. At the same time, the battery was thoroughly cleaned and disinfected, and no further losses occurred after discontinuance of the treatment.

**The occurrence of type 10 paracolon in turkeys**, W. R. HINSHAW and E. MCNEIL. (Univ. Calif.). (*Jour. Bact.*, 51 (1946), No. 3, pp. 281-286).—Antigenic and cultural studies on a coliform organism isolated on 17 ranches from 15 outbreaks in turkey poults and found in adult carriers on 4 ranches showed it to be a paracolon designated by Edwards et al. (E. S. R., 90, p. 825) as type 10. The antigenic structure is XVIII: z<sub>1</sub>x<sub>1</sub>x<sub>2</sub>. The symptoms and pathology observed in these outbreaks resembled those seen in salmonellosis of turkey poults. The mortality ranged from 5 to 70 percent and was most severe during the first 14 days. Agglutination tests conducted on the survivors of acute outbreaks indicate that the infection is more easily aborted than is pullorum disease. The studies add additional evidence that this group of paracolons is of pathogenic significance.

**Isolation of a type 10 paracolon bacillus from an adult turkey**, H. C. GAUGER. (N. C. State. Col.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 299-300).—A *Salmonella*-like organism isolated from a turkey hen serologically positive to a commercial pullorum stained antigen was identified at the Kentucky Experiment Station as a type 10 paracolon bacillus belonging to the

Arizona group with the antigenic formula XVIII: Z<sub>1</sub>X<sub>2</sub>X<sub>1</sub>. The history of the case suggested that this strain was brought into North Carolina by way of infected hatching eggs from California.

**Isolation of *Salmonella typhimurium* from the feces of turkeys,** H. C. GAUGER and R. E. GREAVES. (N. C. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 232-235).—The feces from six turkey breeders naturally infected with *S. typhimurium* were cultured on 17 to 44 days over a period varying from 52 to 70 days, and *S. typhimurium* was recovered from the feces of these six birds on 7, 5, 3, 8, 4, and 8 days, respectively. The total *S. typhimurium* isolations were 35, or 17.5 percent of 200 samples cultured. The last isolation of the organism was made from one bird on the sixty-fifth day of study. At autopsy the organism was recovered from the tissues of one of the six birds. The period during which *S. typhimurium* was isolated from seven artificially infected turkey hens not in production was relatively short. Feces were cultured on 8 to 22 days over a period varying from 20 to 118 days, and the organism was recovered from the seven birds on 3, 3, 4, 4, 3, 3, and 3 days, respectively. All isolations were made within 15 days after the birds were inoculated, and during this 15-day period 32 or 64 per cent of the 50 fecal samples cultured were positive for *S. typhimurium*. At autopsy the organism was recovered from the tissues of one of the seven birds.

**Experiments in the use of sulfathiazole for turkeys,** W. R. HINSHAW and E. McNEIL. (Univ. Calif.). (*Cornell Vet.*, 36 (1946), No. 1, pp. 66-70).—Neither sulfathiazole nor sodium sulfathiazole proved to be effective as a flock treatment for a respiratory disease of turkeys which is common on the West Coast, when given in doses readily accepted by the birds. The drugs were also ineffective against two outbreaks of acute fowl typhoid of turkeys. A deleterious effect on egg production was noted when adult turkeys were given in excess of 0.5 percent sulfathiazole in the mash. Feeds containing sulfathiazole, and water containing sodium sulfathiazole, were unpalatable, especially for young turkeys. Mash pellets containing sulfathiazole appeared to be more distasteful than dry mash containing the same level of the drug.

**Field trials on the use of sulfamerazine for a respiratory disease of turkeys,** E. McNEIL and W. R. HINSHAW. (Univ. Calif.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 273-277).—Following the unsuccessful attempts to use sulfathiazole in the treatment of this disease noted above, beneficial results were obtained when sulfamerazine alone, or in combination with sulfathalidine (Soluble Sulfonamide II), was given in dry mash to turkeys in the early stages of a respiratory disease before the exudate in the air sacs became cascated. No advantage could be observed in using the combined drugs. The sulfonamide blood levels varied from 6 to 20 mg. percent at the 0.5-percent level in the mash and from 5 to 16 mg. percent at a dosage of 0.25 percent for longer periods. As in the treatment of fowl coryza (*Hemophilus* type) with sulfathiazole, symptoms reappeared after treatment was discontinued.

**Limitations of phenothiazine in the control of cecal worms and blackhead disease of turkeys,** E. E. WEHR and L. G. OLIVIER. (U. S. D. A.). (*Poultry Sci.*, 25 (1946), No. 3, pp. 199-203).—Three experiments, involving the rearing of chickens and turkeys together and of turkeys alone, were conducted. Parasite-free birds were placed on soil heavily contaminated with cecal worm eggs and held there for 4 to 6 weeks. During this time one-half of the birds received phenothiazine in the mash and the others were fed plain mash.

Chickens to which a mash containing 1 percent of phenothiazine and turkeys to which a mash containing 2 percent of phenothiazine were fed did not remain free of cecal worms, although the worms were evidently expelled before or soon after they reached maturity. No mature cecal worms were found at autopsy in any of the surviving treated birds or those dying from blackhead. The total number of immature cecal worms removed from the treated birds was about one-third of that removed from the control birds.

In general, there was no significant difference in the number of deaths in the treated and control groups. It is concluded that "regardless of the role that the cecal worm may play in the transmission of blackhead under natural conditions, the practice of feeding phenothiazine in the mash over a period of 4 to 6 weeks to prevent the propagation of this parasite cannot be expected to reduce appreciably blackhead disease."

## AGRICULTURAL ENGINEERING

Ground water in the High Plains of Texas, W. N. WHITE, W. L. BROADHURST and J. W. LANG (*U. S. Geol. Survey, Water-Supply Paper 889-F (1946), pp. 420+, illus. 12*).—Pumping from wells, begun more than 30 yr. ago, increased rapidly from 1934, when 300 wells were pumped, to 1939, in which year 1,700 wells were pumped for the irrigation of 230,000 acres. From measurements in a considerable number of wells in 1914, 1934, 1936, and 1937, and from other information, it is concluded that a large part of the water that has been pumped from wells in this region has been derived by reduction in underground storage.

Soil erosion in small irrigation furrows, O. W. ISRAELSEN, G. D. CLYDE, and C. W. LAURITZEN. (Coop. U. S. D. A.). (*Utah Sta. Bul. 320 (1946), pp. 39, illus. 20*).—From experiments, described as preliminary, upon a silt loam and a sandy loam on two farms and upon a sand used in laboratory work only, the following tentative conclusions are drawn: Irrigation furrow slopes of 2 percent and higher are excessive and cause harmful erosion during the irrigation of loose silty loam and sandy loam soils when streams of 10 gal. per minute, or more, are run into each furrow. Doubling the furrow slope more than doubles the erosion of loose silty loam and sandy loam soils. The erosion on a given furrow slope is dependent on the size of the irrigation stream and length of furrow, and doubling the stream more than doubles the erosion. In furrow slopes of 3 percent or smaller the erosion is less from flat furrows than from V-shaped furrows, and on slopes of 3 percent or higher the erosion is greater from flat furrows. The erosion of loose soil from V-shaped furrows is a maximum at the time when the water first reaches the lower end of the furrow, and it decreases as time advances. Under the conditions of the studies here reported, collecting samples of the water and eroded soil at furrow outlets as a means of measuring amount of erosion is superior to the cross-section method, which gave unsatisfactory results.

Grassed waterways, A. W. EMERSON. (U. S. D. A.). (*Farm Impl. News, 67 (1946), No. 9, pp. 36-38, illus. 7*).—The author notes that grassed waterways have been given "top priority" by Soil Conservation Service District supervisors in 1946. The importance of preserving natural sodded water outlets is noted, but the main emphasis is upon the filling and seeding or sodding of gullies and washes with reproduction, as nearly as possible, of the natural features of the original drainageway. Main advantages of the grassed waterway, in addition to the prevention of further water erosion and soil loss, are held to lie in the facts that sodded drainageways can usually be

crossed with farm machines even when the land is somewhat wet, and that the seeding or sodding eliminates an area which usually supports a growth of weeds, and, after thorough establishment of the grass, adds to the grass area which can be harvested. As essentials of successful practice the following are especially noted: (1) The channel must be sufficiently wide to carry the run-off from the drainage area—should be at least 1 rod wide at the narrowest point; (2) if a waterway has eroded or gullied it should be bladed or plowed in so as to widen and level the channel; (3) immediately after the channel is filled in, the soil should be packed and seeded to grass with a quick cover crop. Bromegrass is considered especially good for the Corn Belt because it forms a very good sod. Millet or Sudan grass are recommended as good in many areas for July 1 seeding, to be left unharvested for fall and spring protection or until the grass is established.

**Rotary soil tillage**, C. W. KELSEY (*Agr. Engin.*, 27 (1946), No. 4, pp. 171-174, *illus.* 9).—The author, president of a company manufacturing rotary tillage machinery, notes patents on rotary plows of unsuccessful design issued before 1860, and the introduction of a "revolutionary new principle" by von Mycnberg in Switzerland in 1910. This principle was that of using small spring- or spring-mounted cutting tools, relatively high rotary speed, and the moving of only a small quantity of soil by each blade in any one revolution. Rotary tillage machines of the general nature indicated are described, and some problems met in their development are discussed.

**Some rotary tillage applications**, J. M. GREENE (*Agr. Engin.*, 27 (1946), No. 4, pp. 175-176, *illus.* 2).—The author, associated with a commercial manufacturer of tillage machines, briefly outlines development of rotary tillage equipment by his company, beginning with experiments on the use of a potato digger as a tillage tool. Applications of the rotary tillage principle here noted include the design and successful use of a machine driven by a tractor power take-off to destroy an infestation of white grubs in U. S. D. A. Forest Service nurseries, the same machines being subsequently used in the preparation of compost by the same agency. An example submitted by a large potato grower is cited, a part of a large field having been tilled by usual methods and a part subjected to rotary tillage. In a severe drought following planting, there were observed "dead and withered plants, the weed infestation, and the small, dwarfed potatoes grown in the section handled by conventional tillage as compared with the healthy plants and full-sized potatoes grown in the rotary-tilled section." The author notes, however, that the examples given represent application of rotary tillage by specialty growers, and that, although these specialized applications are important, "there is great need for well-planned research in the field of general agriculture." He points out a number of specific questions which can be answered only by such investigation.

**Curing concrete with sealing compounds**, R. F. BLANKS, H. S. MEISSNER, and L. H. TUTHILL (*Jour. Amer. Concrete Inst.*, 17 (1946), No. 5, pp. 493-512, *illus.* 2).—Following a brief general discussion of the principles involved in concrete curing, the authors take up methods for the effective use of sealing compounds for this purpose. Included are data for evaluating concrete curing by membrane treatment in terms of equivalent moist curing. The paper discusses preferred methods of curing by use of sealing compounds, and outlines a specification and acceptance test for their purchase.

Except under the most severe drying conditions, as for example during the summer months in the desert regions of the Southwest, it is believed that sealing compounds can be used to obtain the desired degree of curing.

They were found most effective in curing slab work, such as pavement and canal lining, where additional moisture is available from the subgrade, and they are least effective for thin sections and structural members having a high ratio of exposed area to volume. In examinations of much concrete canal lining, cured by various methods, it was noted that crazing of the surface concrete was reduced, or almost completely eliminated, when sealing compounds of the clear or white-pigmented type were used. The surface condition in this respect was improved over that of water or wet-burlap-cured concrete. Concrete cured with black compounds, which were not protected by whitewash, on the other hand, was found to be cracked and crazed more than similar concrete cured with water. When given a radiant heat reflective coating of whitewash, black bituminous sealing compounds were found to give satisfactory results. The whitewash weathered away nonuniformly, leaving the black paint mottled and unsightly, but this method of sealing could be used on concrete later to be backfilled.

A charcoal kiln made of cinder-concrete blocks, A. R. OLSON and H. W. HICOK (*Connecticut [New Haven] Sta. Bul. 494 (1946), pp. 30, illus. 5*).—It is noted that the wood distillation industry, though much stimulated during the war, has again been depressed by cheaper production of methanol, acetic acid, and acetone from materials other than wood to a point at which the charcoal needed by tobacco growers and numerous small industries can profitably be produced locally. For such production, relatively small kilns (of a capacity of from 1 to 2 cords) have been found more efficient than large brick kilns of the beehive type.

Of the two kilns of which the construction is here described and illustrated the smaller (net capacity, 1.1 cord) is shaped to house a 4 x 4 x 8 ft. cord, plus the necessary clearances for long sticks and for air and smoke passages. The 2-cord kiln (net capacity 1.9 cords) is 16 in. higher and 32 in. longer. The capacity of either of these kilns may be increased 25 percent by increasing the width 8 in. to accommodate 5-ft. instead of 4-ft. wood. This will not change appreciably the operations schedule given, but greater widths are not recommended, and in the opinion of the authors, any other increase in plant capacity can be better accomplished by increasing the number of kilns. Both kilns are of the chimney type, smoke being drawn from an opening near the base of one end of the kiln, against which opening a chimney stove is built to provide draft at the beginning of each burn by means of a small supplementary fire. Construction is mainly of standard 8 x 8 x 16 in. blocks, with pier blocks of the same and of half this length for corners and door frame, and 4 x 8 x 16 in. blocks threaded onto suitable lengths of 1 1/4-in. iron or steel pipe to form the roof. Detailed construction directions are illustrated by complete and fully dimensioned drawings. Bills of materials for kilns of both the sizes dealt with are appended. Operating directions cover loading, firing, coaling, closing and cooling, and opening the kiln, and illustrative timing schedules are tabulated.

How cotton ginning is affected by farm mechanized production, C. A. BENNETT. (U. S. D. A.). (*Farm Impl. News, 67 (1946), No. 10, pp. 46-48, 98, illus. 3*).—In general, mechanized cotton production requires additional cleaning, drying, and extracting equipment at the gin and slows down the ginning process. Cotton produced in the arid areas (western Oklahoma, Texas) can be stripped, sledged, or snapped, giving the ginner no serious problem. Cottons grown in areas of greater moisture supply, however, are much better harvested by the spindle picker, and the growth of the plant is more profuse, ranker, and leafier, and contains more moisture in addition to that introduced

by the spindle moisteners of the picker. Also the spindle picker, in spite of cleaning devices built into it, frequently tangles vines, grass, and green leaf into the lint in addition to the types of trash for the removal of which the ordinary gin cleaning equipment is designed. In the experimental studies here noted it was found possible, by using a machinery combination comprising a tower drier, 6-cylinder standard cleaner, big bur machine or master extractor, followed by 12 cylinders of special cleaner, and large size extractor feeders on the gin stands to increase bale values on machine-picked cotton about \$5 above those obtained from a conventional gin set-up of drier, 6-cylinder cleaner, and extractor feeder.

Other experimental work included handling and treatment of the crop before harvesting. Defoliating the cotton plants before the picking permitted the mechanical picker to produce lint averaging one-third of a grade higher than that from fields picked with the leaves on. Defoliation had also the advantages of early harvest, earlier release of the crop land, and better boll weevil control because early working of the soil reduced the food supply available to the weevils before hibernation; and it increased the efficiency of the picker by from 3 to 5 percent. Flame cultivation of the crop was of value because it eliminated grass from the machine-picked cotton. Flame-cultivated cotton yielded a product about one-third of a grade better than that from the hoed crop, whether the cotton was picked by machine or by hand.

**New machinery and new haymaking methods in western Nevada, M. C. HARTLEY** (*Nevada Sta. Bul. 177 (1946), pp. 22, illus. 19*).—This bulletin records results of a survey in which 63 reports from farms in four counties were studied "to determine, insofar as it was feasible, the advantages and disadvantages of the various methods used and kinds of machinery as applied to money cost, labor cost, machine efficiency, and quality of hay." Of the farmers interviewed, 37 used balers, 20 used choppers, and 6 used buck rakes. The last-named implement was used only for wild or meadow hay, however. Of the 37 using balers, 21 found the method to have the advantage of reducing the size of the crew, 17 found the baler to reduce the time spent in haying, 13 found it to make the work in the field easier, 11 found the baled hay easier to feed, and 11 found it to have a good market. Smaller numbers noted other advantages. Twenty-six found baling the most advantageous method in general for themselves, and 11 did not consider baling the method most advantageous to themselves. Of the 20 using choppers, all found this method the most advantageous to themselves, 15 that this method made field work easier and took less time, 13 could do their haying with a smaller crew with the chopper, 11 found the chopped hay easier to feed, and smaller numbers noted other advantages. Of disadvantages of either method, 8 noted the additional cash outlay for the baler, and 1 noted this against the chopper. Small numbers noted other disadvantages in the baler method, no other disadvantages in the use of the field chopper. Various other data obtained in the survey are tabulated and discussed, and reproductions of 19 photographs illustrate some of the less usual technics or equipment found.

**Operation of hay driers in Virginia, R. E. MCKNIGHT.** (Va. A. & M. Col.). (*Agr. Engin., 27 (1946), No. 4, pp. 166, 168*).—Introduced in a region of frequent rain, high humidity, and relatively low temperature, and begun with rather inefficient duct systems, barn hay drying is nevertheless rapidly gaining acceptance in Virginia. The first duct systems, based on T. V. A. recommendations, were designed for only about 10 cu. ft. of air flow per minute per square feet of mow floor, showed a high system resistance, and

gave very uneven pressure distribution. The design air flow was raised to 16 cu. ft. in 1945. Recommendations based on 6 years' experience are, in part, that alfalfa be cut at one-tenth to one-fourth full-bloom stage, other crops according to local advice; the cutting start as soon as most dew is off, no more being cut than can be put in the barn the same afternoon, or that cutting be done so late in the afternoon that no wilting occurs, the hay left in the swath overnight, and no more cut than can be put in the following afternoon; that in good curing weather, 2 hr. in the swath and 2 hr. in the windrow is sufficient; that the hay should be evenly distributed and uniformly packed over the duct system as unloaded; that not less than 4 ft. nor more than 8 ft. be put on the drier as a first loading, with additional loadings not to exceed 6 ft., and final total loading not over 15 ft. deep; that the fan should be started within 2 hr., at most, after the first hay has been put in, all mow doors and roof ventilators to be kept open during curing (a specific fan time-clock schedule is given); and that completeness of curing be tested by shutting off the fan overnight when the top foot of hay appears dry enough, turning on the fan again next morning, and immediately walking over the hay to ascertain if any warm air is coming out. If warm air is felt, the fan should be operated during two more days and rechecked.

In response to an inquiry sent the owner of every hay drier in the State (247 driers in all), the author received an unfavorable report from only one farmer. A number of favorable comments are quoted.

Seven years of hay drying experience, H. ANDERSON (*Agr. Engin.*, 27 (1946), No. 4, pp. 164-165).—A barn-drying and a load-drying system, already tried out in practice, and a projected field-drier method are described by the farmer who devised them. All three methods use heated air.

An ordinary unheated air system having given trouble with mold, a furnace of native stone 7 ft. square and 7 ft. high was built and connected to the barn air intake through a 3 ft. by 7 ft. flue built on the ground and making five 180° turns before entering the barn. Only a part of the air intake was taken from the furnace, and air movement through the flue was slow enough to permit all sparks to drop out, especially at the turns.

The second method of drying with heated air involved drying in open-bottomed racks, of which a number sufficient for storage of the hay were built, together with six 2-wheeled trailers, six sheet-metal ducts 18 in. in diameter and about 4.5 ft. long, and open wooden ducts, 12 in. square and 6 ft. long, of which as many were made as of the racks. In beginning the loading of each rack, one of the metal ducts was placed vertically in the center and held in place by a pin. When the rack was about half loaded, one of the wooden ducts was placed lengthwise of the load on the top of the vertical duct and the load completed to total about 5 tons of the partially cured hay. Such loads were run, six at a time, over six 18-in. diameter outlets of an underground, concrete tile duct system through which heated air from a stoker-fed furnace was driven by a 3 ft., 3-hp. fan. The outlets were connected to the vertical ducts in the loads by means of airtight canvas socks. With the fan blowing air heated to 110°F. through the hay overnight, the hay was dry in the morning. The further handling of the racks of cured hay for storage and feeding is also described. Palatable hay of good quality was produced.

A new plan calls for stemcrushing under hot air blast, followed by passage of the hay between two open aprons, of a length sufficient to permit complete drying of the hay by warm air passing through it, and from the aprons to a baler; the whole operation to be carried out in the field directly after cut-

ting. It is intended to heat the air for this process with an oil burner. It is estimated that the cost of such equipment would be about \$5,000. and that the equipment would handle the hay drying for five farms otherwise requiring \$1,000 expenditure each for a barn hay-curing setup.

Equipment for handling partially cured hay, C. N. TURNER (*Agr. Engin.*, 27 (1946), No. 4, pp. 163, 165).—The author discusses trial barn hay-drier installations worked in cooperation with farmers whose harvesting covered most of the older and newer methods of handling partially cured hay. Though the majority used the side-delivery rake, hay loader, wagon, and hay fork, three farmers used the buck rake and the wind stacker from the rear of the threshing machine. Five used the pick-up field harvester and the hay chopper or blower at the barn. Six used the field pick-up baler both with and without the conveyor handling equipment at the barn, and two the hay loader and truck with the regular hay chopper blower at the barn.

Though a large majority of farmers will judge the barn drier as used with the loader, wagon, and fork handling method, the author is of the opinion that "if the quality of barn-cured hay is sufficient to warrant the additional cost of the barn-curing operation, mechanization of the harvesting operation will probably be warranted by the saving in labor and human effort." Of the transport buck rake, made from a used car or truck, and the old threshing machine wind stacker, he holds that this form of mechanization requires the least capital investment, the least labor, and is the cheapest method of putting hay on the drier when the fields are within  $\frac{1}{2}$  mile of the barn. With respect to either field harvester or loader and truck used with a hay chopper, it is emphasized that the hay should not go into the mow with more than 35 percent moisture content, that care must be taken to avoid overloading the mow because of the greater density of chopped hay, and that adequate air volume cannot be forced through chopped hay of a depth of more than about 14 ft. in the mow. The field pick-up baler and conveyor as combined with barn drying is also discussed, as are conditions and methods for barn drying of baled hay, which is regarded as having about the same density as chopped hay and, accordingly, about the same extra power requirement, in comparison with loose long hay, as does chopped. It is further noted, with respect to baling before drying, that few pick-up baling machines make a satisfactory loose bale and most of them are not built to handle hay containing over 25 percent moisture.

Distribution of air in long hay, A. W. CLYDE. (Pa. Expt. Sta.). (*Agr. Engin.*, 27 (1946), No. 4, pp. 159-161, illus. 2).—By means of an apparatus, here illustrated, for a laboratory study of the flow of air through hay, the author found that the resistance to the flow of air through such material apparently does not follow the law of proportionality of the resistance to the square of the velocity, as in ducts and fixed orifices, but increases at a lower rate due, possibly, to displacement of material and enlargement of air passages. In measuring the air flow out of the hay at various points, the author found the use of a funnel placed with its larger end against the hay and an anemometer at the smaller end to give rough comparisons only, and to require careful calibration if it is to give quantitative results of any value. With a funnel having an area ratio of 20 : 1, the measured exit velocity was from one-third to one-half of the velocity believed actually to exist. Uneven distribution of the air flow due to uneven density seemed to be unavoidable at points where additional hay is repeatedly dropped from a carrier and at points where men stand in moving the hay. A density of 8.4 lb. to the cubic foot after the hay was dried was found under the hay

track in one instance. This difficulty was obviated by two farmers by building platforms upon which the hay was dropped and from which it was distributed.

Corrective measures suggested by the author include a timber so placed as to break the fall of the hay. He also has considerable confidence "that blowing uncut hay into the mow will make for more even density as well as leaving the hay loose and easy to blow air through." Uneven air distribution due to low resistance against escape of air from the sides was reduced, though not entirely prevented, by putting up a smooth wall 6 ft. high against the open side of the hay. Removal of sections of this wall resulted in a strong outflow of air and a reduction of pressure in the duct. It is suggested that side loss might be reduced by restricting ducts to an area 8 ft. from the side walls. It is pointed out, however, that this might leave room only for a main duct, with the possibility of a high entrance resistance. Part or all of the duct might be extended to a height of from 6 to 8 ft. above the floor to take advantage of the tendency of the air to leave from the sides. Concerning the use of built-in resistance in the duct system, the author doubts whether the power loss could be spared from the limited fan horsepower which can be provided. Throttle control of side ducts opening into low-resistance parts of the mow is also discussed. As a final improvement suggestion, two-level duct systems are considered, to avoid the illogical "attempt to blow air through 15 or 20 ft. of hay . . . to dry the last foot." Though wooden second-level ducts have not seemed practicable, it is believed that ducts of sheet metal or of wire mesh might be more adaptable to such use.

Resistance of hay to air flow and its relation to design of barn hay-curing equipment, C. K. SHEDD. (Iowa Expt. Sta. coop. U. S. D. A.). (*Agr. Engin.*, 27 (1946), No. 4, pp. 169-170, illus. 2).—The author measured the resistance of a mixed hay of brome grass and alfalfa and a nearly pure alfalfa hay to air flow in an apparatus the same as that used by him in studying the air flow resistance of ear corn (E. S. R., 93, p. 201) except that an inclined-tube water manometer was employed for determining the static pressure in the plenum chamber under the false floor in the measurements of hay resistance. Each lot of hay was tested at 10, 15, and 20 c. f. m. per square foot of floor area. The results are shown numerically and as plots of the data on logarithmic scales, a method having the advantage that a straight line plot shows that the data conform to the equation  $Q = aP^b$ , in which  $Q$  = air flow in cubic feet per minute per square foot,  $P$  = static pressure, or pressure drop through the hay, in inches of water, and  $a$  and  $b$  are constant for a given depth and condition of the hay. For hay, the value of the exponent  $b$  varied from 0.71 to 0.77, average about 0.75, a figure which the authors compare with corresponding values of 0.50 for ear corn, 0.68 for shelled corn, 0.88 for grain sorghum and for oats in pointing out that "all of these results indicate that air flow through porous materials may not follow the law that velocity varies as the square root of pressure head, but that the velocity may vary as some other power of pressure which can be determined only by experiment."

Apply these results to barn hay-drier design, the author shows that although an air flow of 10 c. f. m. per square foot has sometimes been found insufficient to cure the hay without some spoilage, the suggested remedy of increasing the flow to 15 c. f. m. would increase static pressure by the factor 1.8 and the power requirement by the factor 2.7, the calculation covering only the resistance within the hay itself. The proposed flow of 15 cu. ft.

cannot, therefore, be obtained "without some improvements in design" within the probable practical limit of 5 hp. set by the usual limit of farm transformer capacity. Other applications of the results here recorded to barn drier design are also suggested.

Curing hay in the stack with forced air, J. H. RAMSER and E. W. LEHMANN. (Univ. Ill.). (*Agr. Engin.*, 27 (1946), No. 4, pp. 167-168, illus. 4).—The experiments here reported upon were made with the purpose of developing a method for producing high quality hay where neither barn-curing space nor electric power are available. Essential differences between the plan here described and earlier stack drying methods lie in the type of duct, the special design of the portable blower, and the use of a porous fiberglass tarpaulin to cover the upper part of the stack for protection against rain and to equalize the air flow through the hay.

The main duct took the form of an A frame 14 ft. long. The framework was built of 2 x 4's 2 ft. apart, covered with 1 x 4-in. strips 1 ft. apart. The over-all cross-sectional dimensions of the A frame were 3 ft. wide at the bottom and 1 ft. at the top with a vertical height of 5 ft. This gave a free area for air passage of approximately 6½ sq. ft. From the fan and motor enclosure to the A frame, a tight connecting duct 8 ft. long with framing inside was used. To ventilate at hay over this connecting duct, slots 1½ in. wide extending halfway from the A frame to the motor enclosure were left on each side at the bottom and in the center of the top.

A 15-hp. internal-combustion engine, such as is used on a small tractor, was used and was directly connected to an 8-blade propeller-type fan. The fan and engine unit was enclosed by a 5- by 5-ft. structure so that all the air to the fan passed over the engine. The heat given off by the engine raised the temperature of the circulating air approximately 5°F.

A commercial moisture-resistant paper was placed under the stack to prevent damage by moisture from the ground. The base of the stack extended 8 ft. in all directions from the A frame, making the base dimensions of the stack 19 by 30 ft. The sides of the stack were sloped about the same as the sides of the A frame, and the stack extended 8 ft. above the top of the frame, making a total height of 13 ft. and approximately 13 ft. across the top.

Some operational data given are considered to indicate that the cross-section area of the main duct should be increased to lower unnecessarily high air velocities.

Peach research aided by new machine, G. W. GILES and O. VEERHOFF (*Res. and Farming* [North Carolina Sta.], 4 (1946), *Prog. Rpt.* 2, pp. 4-5, illus. 1).—This machine, described as a "counter-sizer," counts and records the peaches in each size when attached to a commercial grader that drops all peaches into one of four sizes. The entire machine is powered by a small gasoline engine. Peaches are picked up individually by the machine at one end and carried through it by cups attached to two parallel endless belts. The weight of the peach causes the cup to trip at the proper weight-size bin, and, at the same time, the movement of the cup is transferred through a lever system to a counter for that weight-size. In order that fruit from small blocks of trees could be run, the two belts were set up so that they could be run separately, with a separate set of counters for each belt. Grading could then be done faster because a sample could be run on each belt, at the rate of 100 peaches per minute.

Cold storage design for apples and pears, W. V. HUKILL and E. SMITH. (U. S. D. A.). (*Refrig. Engin.*, 51 (1946), No. 5, pp. 419-422, illus. 2).—

This paper (covering in condensed form the topics of precooling; capacity and height of rooms and their lay-out; fans, ducts, and air flow; and handling equipment) consists of excerpts from U. S. D. A. Circular 740 E. S. R., 94, p. 814).

**Technical phases of home freezer development, C. E. LUND** (*Refrig. Engin.*, 51 (1946), No. 6, pp. 513-520, illus. 13).—The author first considers cabinet dimensions, limited in width to 29 in. by the average width of doorways and in height by the need of easy accessibility for persons of less than normal stature, leaving only length variable for possible variation in capacity. Experimental data affecting the design are concerned with effects of insulation thickness, temperature gradients with and without load, effects of 2.5-in. and of 4-in. lid insulation (the thicker insulation reducing the running time of the cooling unity by only 3 percent in a 9-cu.-ft. cabinet held to 0° F. in an ambient air temperature of 100°), temperature gradient through a loaded cabinet during warm-up (measured to determine the effect of power shut-off or mechanical break-down), vapor transmission sealing of cabinet wall, effect of single and double door gaskets on vapor transmission, performance data of home type freezer cabinets, etc.

**The walk-in type of milking barn, F. B. HEADLEY** (*Nevada Sta. Bul.* 176 (1945), pp. 5, illus. 2).—From experience with a barn of this type, built in 1944 by the station, the author concludes that a milking room need not be larger than 12 by 38 ft. to be sufficient for a 75-cow herd. Though there is additional expense for the individual stalls and a raised platform on which the cows stand, the lower cost of the small barn more than offsets this. Because each cow occupies the milking stall for usually less than 5 min., the walk-in barn is easier to keep clean, can be kept practically free from odors, and makes it easier to produce milk of low bacterial count. At the station barn, a milking rate of 25 to 30 cows per man per hour was attained.

The bulletin contains brief notes on milking procedure and number of stalls and shows the lay-out of a walk-in milking barn and dairy room.

**Housing for pigeons, C. S. PLATT** (*New Jersey Stas. Hints to Poultrymen*, 32 (1945), No. 5, pp. [4], illus. 2).—A practical discussion. The author advises that a detailed construction blueprint for a unit which accommodates 15 pairs of birds is available upon request.

## AGRICULTURAL ECONOMICS

[Papers on agricultural economics] (*Jour. Farm Econ.*, 28 (1946), No. 1, pp. 409+).—Included are the following papers, with discussions on some, presented at the annual meeting of the American Farm Economic Association at Chicago, Ill., December 27-28, 1945: Postwar Agricultural Policy—Pressure vs. General Welfare, by O. B. Jesness (pp. 1-14) (Univ. Minn.); Changes in Economic Structure Affecting American Agriculture, by T. W. Schultz (pp. 15-27); Sixty Million Jobs and Six Million Farmers, by F. A. Pearson and D. Paarlberg (pp. 28-41) (Cornell Univ.); The Prospect for Postwar Agricultural Exports From the United States, by R. B. Schwenger (pp. 42-53) (U. S. D. A.); Food and Agriculture Organization of the United Nations, by P. L. Yates (pp. 54-70); Educational Opportunities and Responsibilities in Foreign Agriculture, by C. L. Stewart (pp. 71-80) (Univ. Ill.); Social Security for Farm People, by I. S. Falk and W. J. Cohen (pp. 84-96); also by K. H. Parsons (pp. 97-110) (Univ. Wis.); Research Developments in Farm Finance, by F. F. Hill (pp. 114-125) (Cornell Univ.); Research Work in Minimum Financial Requirements and Some Related Considerations for

Beginning Farming, by W. L. Cavert (pp. 126-133) (U. S. D. A.); Research Developments in Cooperative Marketing, by H. Hedges (pp. 134-140) (U. S. D. A.); Research and Educational Programs in the Marketing of Milk and Dairy Products, by A. MacLeod (pp. 144-157); Research and Educational Programs in the Marketing of Livestock, by C. D. Phillips (pp. 158-169) (Univ. Ky.); Some Considerations of Research in Marketing Horticultural Products, by H. R. Wellman and G. L. Mehren (pp. 170-181) (Univ. Calif.); Postwar Extension Problems in Agricultural marketing, by W. B. Stout (pp. 187-198) (U. S. D. A.); Postwar Extension Problems in General Agricultural Economics, by G. W. Westcott (pp. 199-212) (Mass. State Col.); Postwar Extension Problems in Farm Management, by C. Malone (pp. 213-226) (Iowa State Col.); Postwar Agricultural Problems in the Great Plains Area, by W. E. Grimes (pp. 235-242) (Kans. State Col.); in the Corn Belt by C. W. Crickman (pp. 243-260) (U. S. D. A.); and in the Dairy Regions, by L. C. Cunningham (pp. 261-264) (Cornell Univ.); Basic Weaknesses of the Parity Price Formula for a Period of Extensive Adjustments in Agriculture, by K. T. Wright (pp. 294-300) (Mich. State Col.); Parity Prices, by O. C. Stine (pp. 301-305) (U. S. D. A.); Agricultural Economists and Public Opinion, by L. J. Norton (pp. 306-310) (Univ. Ill.); Extension Use of Farm Work Simplification, by R. E. Proctor (pp. 314-319) (Univ. Ky.); An Analysis of Work Simplification Research Methods and Results, by L. S. Hardin and R. M. Carter (pp. 320-330) (Purdue Univ. and Univ. Vt.); and The Future of Farm Work Simplification Research, by E. C. Young and I. R. Bierly (pp. 331-337) (Purdue Univ. and Cornell Univ.).

Also included are: A topical digest of the winning papers in the farm price policy awards (noted on page 581), by W. H. Nicholls and D. G. Johnson (pp. 267-283); a discussion of the price policy award papers, by L. H. Simerl (pp. 284-289); and a discussion of the price policy winning papers, by R. K. Froker (pp. 290-293) (Univ. Wis.). A report, Adjustments in Southern Agriculture with Special Reference to Cotton (pp. 341-379), prepared by a special committee of the association; and the report, Outline of a Price Policy for American Agriculture for the Postwar Period (pp. 380-397), of the Committee on Parity Concepts, are given.

[Papers and notes on agricultural economics] (*Jour. Farm Econ.*, 27 (1945), No. 4, pp. 903-989, illus. 3).—Included are the following papers, with discussions: Wartime Experience in Production Adjustment Research and Future Possibilities, by N. W. Johnson (pp. 903-927) (U. S. D. A.); Mechanization of the Cotton Harvest, by F. J. Welch and D. G. Miley (pp. 928-946) (Miss. Expt. Sta.); A Critical Examination of Marketing Research, by F. L. Thomsen (pp. 947-962) (U. S. D. A.); and Analyzing Labor Requirements for California's Major Seasonal Crop Operations, by M. W. Lenhart (pp. 963-975). Notes are also included, as follows: Will Governmental Programs Alter the Structure of Government? by O. B. Jesness (pp. 976-980) (Univ. Minn.); Farm Real Estate Values in South Dakota and the BAE Index of Estimated Value Per Acre of Farm Real Estate, by G. Lundy (pp. 980-984) (S. Dak. State Col.); and The Consistency of U. S. D. A. Estimates of Possible Consumption and Prices of Beef and Pork in 1950, by Z. Szatrowski (pp. 984-989).

Changes in the apple industry in Maine, C. H. MERCHANT (*Maine Sta. Bul.* 440 (1945), pp. 35-63+, illus. 9).—This report is based upon interviews with apple growers throughout the State in 1940 and in 1943 and 1944, concerning their orchards and the storage and marketing of the apple crops; on earlier surveys made by the station; and on United States census reports for

1924, 1934, and 1939, as to the number of trees, etc. Analyses are made of the trends in the number of apple trees in the State, varieties and ages of trees, size of orchards, and relation of size to varieties, etc., in commercial orchards. The kinds of storage, transportation facilities, methods of grading, packaging, and selling apples, and the changes in each are discussed.

From 1924 to 1939, according to the census, there was a decrease of 77 percent in the number of bearing apple trees and 74 percent in the number of nonbearing trees. Most of the decrease was in farm orchards and neglected commercial orchards. "A survey of 305 farms in 1943 and 1944 indicates that more than one-half of the apple trees are of the McIntosh variety. Also, a large proportion of the McIntosh trees are comparatively young and a relatively high percentage are not yet in bearing. The Delicious and Cortland varieties continue to increase in importance but not at the same rapid rate as McIntosh. The winter varieties such as Baldwin, Rhode Island Greening, Stark, and Ben Davis are declining in importance. The Northern Spy variety has sufficient young trees to maintain the present production of apples for several years. It seems reasonable to expect that future apple crops will consist very largely of fall varieties, especially McIntosh, with a distinct decline in winter varieties with the possible exception of Northern Spy." There was a definite trend towards larger orchards, and the trend is expected to continue. During recent years more and better storage facilities have been made available, and further development, especially of cold storage, is expected. An increasing quantity of apples has been moving into storage and to markets by trucks, and it is expected a higher percentage of the crop will be so moved in the future. The two most important changes in selling apples have been the change from barrels to boxes as containers, and the increase in the percentage of apples being sold to retailers and wholesalers and the decrease in percentage being sold to country buyers.

Costs and returns in broiler production, A. L. PERRY and G. F. DOW (*Maine Sta. Bul. 441 (1945), pp. 65-116+, illus. 5*).—Data were obtained from 170 broiler growers who raised at least 500 broilers each during the year ended June 30, 1944, regarding the costs, returns, and practices in raising chickens for meat. Analyses are made of the costs and returns and the factors affecting them. Among the factors and practices discussed are: Number of broilers raised per farm and per lot; type of producer; use of labor; rate of growth; mortality; source and price of baby chicks; sex of chicks, and separation of pullets and cockerels; breed of chickens; month chickens were started; age and weight at sale; chicks per stove, and space per chick; fuel used in brooder stoves; feeding and watering; use of range; type of litter and floors; use of lights; and use of credit. The quality and weight of broilers desired by buyers, markets and marketing channels, seasonality of marketing, and broiler prices are discussed briefly.

Production costs averaged 24.3 ct. per pound of meat and returns 29.1 ct. The average profit of 4.8 ct. per pound represented a labor return of \$1.40 per hour. Producers with less than 1,000 broilers per year had a profit of only \$76 as compared with \$2,567 for those raising 8,000 or more broilers. Of the production costs, feed comprised 63 percent, baby chicks 14, labor 14, use of buildings and equipment 5, and miscellaneous costs 4 percent. The daily labor requirement per 1,000 chicks started was 1.6 hr. for regular chores and 0.4 hr. for miscellaneous work. The average rate of growth per day was 3.8 lb. per 100 broilers. Variation in rate of growth accounted for a difference of 8.5 ct. per pound in the cost of production. Broiler Crosses and Plymouth Rocks made the most rapid gains and used feed more efficiently

than other breeds. Broilers sold at 14 weeks of age, at a weight of nearly 4 lb. per bird, had the lowest cost per pound of meat. Costs increased very rapidly for chicks kept to 20 weeks of age or older. An average of 4.5 lb. of feed was required per pound of meat.

Milk prices need adjustment seasonally to stimulate greater fall production, C. W. PIERCE (*Pennsylvania Sta. Bul.* 475 (1946), *Sup.* 1, pp. 6-8, *illus.* 2).—The problem and causes of fall shortages of milk in the Philadelphia market are discussed and suggestions made for seasonal adjustment in milk prices to stimulate greater fall production.

A price policy for agriculture, consistent with economic progress, that will promote adequate and more stable income from farming (*Jour. Farm Econ.* 27 (1915), No. 4, pp. 737-902, *illus.* 3).—Under an agreement of February 3, 1945, between the American Farm Economic Association and W. H. Jasspon, the donor of \$12,500, a contest was sponsored and conducted by the association for the best papers on the subject of Farm Price Policies. The awards were: First, \$5,000; second, \$2,500; third, \$1,250; and 15 additional awards of \$250 each. The specific topic announced for the contest was A Price Policy for Agriculture, Consistent with Economic Progress, That Will Promote Adequate and More Stable Income from Farming. The authors and papers receiving the principal awards were: First award, W. H. Nicholls (pp. 743-760), and second award, D. G. Johnson (pp. 761-772) (both Univ. Chicago); and third award, F. V. Waugh (pp. 773-784) (U. S. D. A.). The 15 additional awards were made to the following authors: G. W. Barr (pp. 785-789) (Univ. Ariz.), M. K. Bennett (pp. 790-797) (Stanford Univ.), G. P. Boals (pp. 798-806) (U. S. D. A.), K. Brandt (pp. 807-812) (Stanford Univ.), W. W. Cochrane (pp. 813-820) (U. S. D. A.), R. J. Eggert (pp. 821-828) (Amer. Meat Inst.), P. A. Eke (pp. 829-836) (Univ. Idaho), C. C. Farrington (pp. 837-843) (U. S. D. A.), R. K. Froker (pp. 844-851) (Univ. Wis.), C. D. Hyson (pp. 852-860) (Harvard Univ.), A. L. Larson (pp. 861-870) (Okla. A. and M. Col.), J. G. Maddox (pp. 871-877) and R. Schickele (pp. 878-885) (both U. S. D. A.), G. Shepherd (pp. 886-894) (Iowa State Col.), and L. H. Simerl (pp. 895-902) (Ill. Agr. Assoc.). The texts of the papers are given.

Brief statements are included by L. J. Norton, president of the association, regarding the contest, and by C. C. Davis, chairman of the award judges.

Cropland use and soil fertility practices in war and peace, D. B. IBACH (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, F. M.* 52, pp. 58+, *illus.* 14).—“This report does not include data, quantitative estimates, suggestions, or discussion of all the important factors that are associated with soil fertility or other aspects of physical productivity. It is limited primarily to suggestions for postwar land use and practices considered by State production adjustment committees, compared with similar items for the prewar and wartime periods. . . . The terms ‘prewar,’ ‘wartime,’ and ‘suggested postwar’ refer to the periods of 1935-39, 1943, and about 1950 respectively, unless otherwise stated.” The prewar, wartime, and suggested postwar use of cropland in the Corn Belt and the Lake, Appalachian, Southeast and Delta, Mountain and Plains, Pacific Coast, and Northeast States; fertility practices by regions and classes of crops, including consumption trends and suggested postwar use, suggested regional changes in fertilizer consumption and in extent of application, and suggested changes in use by classes of crops and pasture; consumption trends and suggested postwar use of lime; and the use of manure are discussed. Other sections deal with government measures

for maintenance of soil fertility; miscellaneous fertility and other practices, including winter cover crops, summer fallowing, and terracing and contouring; and the implications of wartime changes and suggested postwar changes, including farming adjustments and soil fertility, fertility losses and farming costs, fertilizer expenditures and agricultural adjustment payments, improved practices and production of export crops, and farming adjustments and agricultural output.

[Economic land classification in Virginia counties] (*Virginia Sta. Buls.* 373 (1945), pp. 9, illus. 1; 377, pp. 10, illus. 1; 380, pp. 9, illus. 1; 381, pp. 9, illus. 1; 387 (1946), pp. 8, illus. 1).—These bulletins continue the series (E. S. R., 95, p. 260). The counties covered are: Bulletins 373 Southampton, and 387 Loudoun, by G. W. Patteson and S. C. Shull; and 377 Augusta, 380 New Kent, and 381 Charles City, by G. W. Patteson and J. A. McCartney.

Typical family-operated farms, 1930-45: Adjustments, costs, and returns, W. D. GOODSELL, R. W. JONES, and R. W. BIERMAN (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, F. M. 55, pp. 91+, illus. 24*).—This publication consists chiefly of tables and charts, with a minimum of discussion, and is intended primarily "for the administrators, the researchers, and the students and individuals who are interested in the various aspects of agriculture and agricultural development. It presents basic data on farm organization, production, production efficiencies, mechanization, investment, income, prices, costs, and returns to capital and labor in each year from 1930 to 1945 on commercial family-operated farms of given sizes and types in a number of the more important agricultural areas in the United States." Each of the farm units included is an "area-type" farm organization which represents the great mass of commercial family-operated farms of the respective type in the area. In each particular, each 'area-type' farm is the mean or the average of commercial family-operated farms of given type, the limits of which span the practical range of family-size farms of the specified type in the designated area." Fourteen types of farms are included, as follows: Dairy, in central New York and in southern Wisconsin; cash-grain, hog-beef, hog-beef fattening, hog-feet raising, and hog-dairy, in the Corn Belt; wheat-corn livestock; wheat-small grain-livestock, wheat-roughage-livestock, in the Northern Plains; wheat and wheat-grain sorghum, in the Southern Plains; cotton-grain sorghum, in the Southern Plains; cotton, in the Black Prairie area, Texas; and cotton, in the Delta area of Mississippi. A map shows the location of the 14 types of farms included in the report and 12 others that have been studied. The terms used in the report are discussed under the headings: Size, investment, and income; allocation of net farm income; and index, numbers of production, costs and returns. Most of the index numbers are based on 1930-44 = 100. Supplemental tables are also included on the basis of 1935-39 = 100. Charts compare the following items for the 14 areas: Operator's net income; total farm expenses, rent and interest paid by operator, and operator's net income; total production and total production costs; combined average yields of major crops; production per hour of man labor and costs per unit of production; prices received and prices and wages paid; operating expense per dollar of gross farm income; equity of operators in their farms; and net rent as percent of current value of land and buildings and estimated value per acre of farm real estate. Tables show for each year, 1930-45, for each farm type, operator's net farm and net cash farm incomes; net farm income and return to operator and family labor; return per hour to all labor, total hours of labor used, and total farm investment; total cost per unit of production and production per

hour of man labor; and total production and operating expense per dollar of gross farm income. The location and characteristics of each of the typical farms are discussed, with charts covering 1930-45 showing for each farm the gross and net farm incomes, total expense, rent and interest paid, and operator's net farm income; and tables showing land use, livestock numbers, and distribution of income and expense, and investment, income, and related factors.

**Typical family-operated farms, 1930-45: An historical look to the future,** R. W. JONES and W. D. GOODSSELL (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, F. M. 56, pp. 24 +, illus. 13*).—Certain aspects of the material in F. M. 55, noted above, are dealt with more generally in sections entitled: What About Farmer's Income; Why Some Farmers Have Higher Earnings Than Others; Are Farmers Progressing Toward Owner-Operatorship; How Much of Gross Farm Income is Net; and Land Boom Ahead. The map showing the location of the types of farms studied and all the charts in F. M. 55 comparing the various items for the 14 types are included, except that showing production and production costs. Additional charts show the operating expenses per unit of production; production per farm; mechanization and size of farm; and why farmers' incomes differ.

**Paying for a farm,** J. L. ROBINSON and G. F. EKSTROM (*U. S. Dept. Agr., Farm Credit Admin. Cir. E-30 (1946), pp. 19, illus. 6*).—"This circular is designed chiefly as an aid to instructors of vocational agriculture in organizing teaching units on agricultural credit and for them and others in advising young men on credit problems related to the purchase of land and to the operation of farms." Certain principles that the Farm Credit Administration has found to be basic to the use of credit in farming are set up and supported by data obtained from research dealing with the relationship of land classes to debt repayment ability. The chief study was one of over 11,000 loans made by the Federal Land Bank of Spokane in 30 counties of Washington, Idaho, and Montana.

**Cotton crop insurance in Tennessee and United States,** B. D. RASKOFF and E. B. FICKEL (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 198 (1946), pp. 29 +, illus. 11*).—"This report covers: (1) Cotton crop insurance experience in Tennessee for 1942 and 1943, with some data for 1945 and 1946, and some comparisons with experience in other States, (2) loss experience on sample farms for the period of 1935 to 1941, and (3) factors for consideration in future planning." The section on cotton insurance experience deals with the extent of participation, average check rate and check yield, proportion of farms having losses, indemnities paid and premiums collected, and causes of indemnified losses. The section on factors for consideration in future planning discusses the yield trend; yield per acre; proportion of cotton acreage abandoned; volume, distribution, and value of the crop; the estimated reduction in yields due to climatic factors, diseases, insects, and other causes; and the loss experience on farms in the western part of the State. A bibliography of 18 references is included.

Federal crop insurance, available to Tennessee farmers on the cotton crops of 1942, 1943, 1945, and 1946, was carried by about 14,485 growers. This represents an average participation in the program by cotton producers of less than 5 percent. The low participation was largely due to high cotton yields during recent years and lower than average cotton crop losses.

**Irrigation companies in Utah: Their activities and needs,** O. W. ISRAELSEN, J. H. MAUGHAN, and G. P. SOUTH. (Coop. U. S. D. A.) (*Utah Sta. Bul. 322 (1946), pp. 62 +, illus. 25*).—This survey of the irrigation com-

panies of Utah is made in cooperation with the Utah State Department of Publicity and Industrial Development. It had for its major purposes "to obtain information concerning the supplemental water needs of Utah irrigation companies; to find the necessary physical improvements and additions to water storage and conveyance facilities; to define the major problems that must be solved in order to make the necessary improvements, and to assist public agencies toward coordinating irrigation research with planning and operations designed to improve irrigation facilities and increase crop production." The information was obtained largely by personal conferences with irrigation company officials, using a detailed schedule covering general information (history, management, etc., of the companies), water supply and irrigated areas, irrigation works, shares of stocks and annual costs, and irrigation company improvements and problems. It covered 509 companies, each irrigating over 300 acres, and 179 irrigating less than 300 acres each, the greater part of the analysis being on the data from the 509 companies. Tables show by counties and drainage areas the class of water supply as to adequacy and the need for supplemental water. The progress and possibilities of reservoir storage are discussed. Estimates are made by counties of the number and cost of diversion and conveyance works needed to be constructed, repaired, or altered. Farm irrigation improvements, water supply measurements, water delivery methods, water rights, annual costs, market value of irrigation stock, etc., are discussed. The functions and responsibilities of irrigation companies and the historical development of such companies in Utah are described.

[Haymaking methods], S. A. ENGINE, (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 8-10, illus. 4).—Tables and discussion based on visits to 80 southern Minnesota farms in 1945 show for different methods of putting up hay the man hours required per ton, tons of hay put up in 5 hr., size of crew, investment in and annual cost for haying equipment, and estimated cost per ton of putting up hay.

Marketing of cottonseed in Louisiana, J. F. HUDSON (*Louisiana Sta. Bul.* 400 (1946), pp. 26, illus. 3).—"The main purposes of this report are to analyze the agencies used by farmers in marketing cottonseed, the buying and selling practices of ginners, and the relationship between the average farm price of cottonseed and the value of the products obtained from cottonseed." The survey method was used in obtaining the data on methods and practices used in marketing cottonseed in the State. Ninety-five schedules were obtained from farmers and 49 from ginners located in the four cotton grade and staple divisions of the State. Among other subjects discussed are the farm income from cottonseed, marketing of the seed, proportion sold, time and place of sale, prices received, variations in grades, price margins, methods for determining weight of cottonseed, other trade practices affecting the ginners' price margins, and how margins might be reduced.

During the 1943-44 season, farmers sold 86.9 percent of the seed to ginners, 0.2 direct to oil mills, and 3.3 for planting seed, and retained 7.2 for home use as seed and 2.4 percent for feed for livestock and fertilizer. Eighty percent of the seed sold to ginners was sold at the time of ginning. The average margins per ton retained by ginners varied from -69 ct. to \$8.40, averaging \$3.65. The seasonal average value of cottonseed products produced per ton of seed crushed in 1943 was \$71.76 and the farm price \$51.60, or 71.9 percent of the value of the products.

The status of cooperatives in fruit and vegetable canning, 1943 and 1944, G. M. WEBER (*U. S. Dept. Agr., Farm Credit Admin., Misc. Rpt. 97* (1946),

pp. 15 +, *illus.* 4).—The total pack by cooperative associations, the location of canning cooperatives, the concentration of output in the larger associations, what fruits and vegetables cooperatives pack, and the outlook for the future are discussed. Tables show by States the number of cooperative associations canning seasonal vegetables and deciduous fruits and berries in 1944, with the annual average percentage of the total cooperative pack in 1943 and 1944; the number of associations packing the principal vegetables and fruits in 1939, 1943, and 1944; percentages of cooperative and total United States pack of the principal vegetables and fruits by specified vegetables and fruits in 1943 and 1944; and the per capita U. S. civilian consumption of fruits and vegetables, 1910-14 to 1940-43, and by years, 1940 to 1943. Charts show the U. S. production of vegetables, fruits, and citrus products, 1943 and 1944, and the percentages packed by cooperatives; and the per capita consumption by years, 1909-43, of canned vegetables and fruits, fruit and tomato juices, dried fruits, and frozen fruits and vegetables.

**Agricultural statistics, 1945**, R. K. SMITH ET AL. (*U. S. Dept. Agr., 1945, pp. 604 +*).—This annual volume (E. S. R., 93, p. 89), prepared under the direction of the Yearbook Statistical Committee, brings together in condensed form the more important series of statistics prepared in the Department or compiled by the staff for official use. The 710 tables are grouped under the headings: Grains; cotton, sugar, and tobacco; oilseeds, fats, and oils; fruits, vegetables, melons, and tree nuts; hay, seeds, and minor field crops; beef cattle, hogs, sheep, horses, and mules; dairy and poultry products; farm capital and income; agricultural conservation and adjustment; and miscellaneous statistics.

**Farm production, farm disposition, and value of principal crops, 1944-45, by States** (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, pp. 61 +, illus. 2*).—Estimates are included for different grains, hay, different seeds, potatoes, fruits and nuts, beans, broomcorn, buckwheat, cowpeas, flaxseed, hops, maple products, peas, peanuts, popcorn, rice, sorgho and sugarcane sirups, soybeans, sweet potatoes, and velvetbeans. Cotton, cottonseed, tobacco, sugar beets, and sugarcane are not included.

**Cash receipts from farming by States and commodities, calendar years 1924-44** (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, pp. 183 +, illus. 12*).—Tables present State estimates of cash receipts from crops and livestock by commodities for the calendar years 1924-44, of government payments for the calendar years 1933-44, and of the value of crops and livestock and livestock products consumed by families on farms where produced, 1924-44.

**Commodity futures statistics, July 1914-June 1945** (*U. S. Dept. Agr., Prod. and Market. Admin., 1946, CS-17, pp. 36 +*).—This is a continuation of the series (E. S. R., 93, p. 89) representing data on the volume of trading, open contracts, future prices, contracts settled by delivery, and trades and commitments of reporting traders in commodities covered by the Commodity Exchange Act. "The statistics are compiled from reports required of exchange clearing members and large traders by regulations promulgated under the act, and from official price records of contract markets."

**Crops and Markets [April 1946]** (*U. S. Dept. Agr., Crops and Markets, 23 (1946), No. 2, pp. 73-108*).—Included are tables of the usual types covering farm employment and wage rates; prices received and paid by farmers, etc.; crop, livestock, and market reports of the usual types; crop production, 1933-45; crop yields, 1929-45; indicated yield or condition of selected crops; planted and harvested acreages, 1931-46; and prospective plantings, March 1946.

## RURAL SOCIOLOGY

Minnesota's farm population prospects, L. NELSON (*Minnesota Sta.*, [1945], pp. 24+, illus. 8).—The author concludes that after the war the farm population of Minnesota may be expected to rise somewhat above the low level to which it has declined during wartime, the amount of increase depending almost entirely upon the state of industrial activity outside of agriculture. The farm population for the past 20 yr. has been fluctuating around 900,000. In good times it has gone below and in bad times above that point by several thousand. If it rises above 900,000 it would indicate a rather serious industrial depression, which will be reflected in falling agricultural prices. In reasonably good times, we should expect it to be considerably below that figure. It is estimated that some 6,000 vacancies take place annually in the labor force, so that about 3,000 of the more than 9,000 boys who reach the age of 18 each year on Minnesota farms would need to move to the cities. Prospective developments call for careful planning in advance if unfortunate land settlement is not to recur. As regards acreage in operated farms, the trend has been opposite to that for the population, and there is larger acreage in fewer farms operated by fewer people. The over-all trend in the population of the United States and of Minnesota is towards a "leveling-off" in the total number of people.

"Johnny didn't pass this year"—rural schools face a major problem, S. C. MAYO (*Res. and Farming* [North Carolina Sta.], 4 (1946), *Prog. Rpt.* 2, pp. 5, 6, illus. 2).—In 1940, out of 640,907 boys and girls 8 through 16 yr. of age attending school in North Carolina, 212,044 were retarded one or more grades. Retardation is an especially serious problem in rural areas and especially among rural-farm youths, involving some 38.2 percent of the rural-farm children 8 through 16 yr. of age (43.9 percent of the boys and 32.5 percent of the girls) and more than half of the rural-farm boys 12, 13, 14, and 15 yr. of age. A larger proportion of boys than girls were retarded in all three residence classes—urban, rural-farm, and rural-nonfarm—and in all ages of each group. The problem is particularly severe among Negroes, (51.1 percent of all Negro youths 8 through 16 yr. of age in the State retarded as compared with 25.6 percent of the white boys and girls), and including 63.4 percent of the rural-farm Negro boys.

Washington high school graduates in depression and in war years, P. H. LANDIS (*Washington Sta. Bul.* 463 (1945), pp. 20, illus. 12).—In Washington, more girls than boys have attended high school since the earliest period of this study, 1934 (E. S. R., 88, p. 542.). The ratio of boys to girls began to drop further during the first year of the war, and the third war-year class was 25 boys per hundred women short. The proportion of Washington boys entering the armed forces immediately after high school graduation increased from 5.2 percent in 1942 to 43.3 percent in 1944, but the proportion entering the work world decreased during this period.

Although the number of Washington girls in college increased a great deal during the third war year over previous periods, the total number continuing their education in all kinds of schools was less in 1944 than during the depression and prewar period. Of the 1944 class, 5.9 percent entered schools of nursing, the highest percentage for the period. Commercial schools had almost a third less registrants from the 1944 class than from the prewar classes.

Store and office work prior to the war offered an outlet for 44 percent of the boys, but during 1944 only 1.2 percent entered this kind of work. Fac-

tory work and trades also drew a smaller percentage of the 1944 class. Few girls and rural boys continued in high school as postgraduates after graduation; 6.8 percent of the rural boys went on to college. This was a slightly higher proportion than of the class of 1943.

Of the boys a majority entered the armed forces immediately after high school graduation in 1944. Fewer girls were in the labor market than of the preceding war period graduating classes, but almost twice as many found work as in the prewar period. Rural boys apparently were not to any great extent using agriculture as a way of avoiding service in the armed forces. A much higher proportion of youth from metropolitan and larger cities continue their school beyond high school than of rural youth. A somewhat higher proportion of young women from urban than from rural areas also continue their training beyond high school, although the differences are not so great as for young men.

**Rural social trends in New York: Their implications for extension activities,** W. A. ANDERSON (*N. Y. State Col. Agr., Cornell [Ext.] Misc. Bul. 2 (1946), pp. 11 +*).—Social trends in New York State have resulted in rapid increases in the rural population, particularly in the rural-nonfarm inhabitants of the State. These changes result from the revolutions in transportation, and communication, the mechanization of farming and the rural home, and major developments in three social institutions, namely the school, co-operatives, and government. The process of creating cultural unification has significant implications for extension activities. Paramount among these is the problem of rural-community organization. These new changes, with new populations and new social class structures, may develop sharp segregations in rural communities or they may be guided into constructive community living. The increased mechanization of farming demands keen management and technical ability that calls for more education. The differences between farm owners and farm laborers may be sharpened. Farm laborers constitute one-third of the persons employed in New York agriculture. Part-time and subsistence farmers are significant in the new rural life. Rural-family participation in organizations is largely passive, and the active participants are chiefly from the larger income families. This means that extension organizations are socially selective and the younger families and those on poor lands are not active. The rural church must evolve a constructive centralization. Schools, taxes, and questions of local government present problems that extension can help to solve. Rural areas were, only three decades ago, almost completely organized on an intimate, face-to-face basis. Today a new impersonal rural life will be evolved unless extension agencies, by a program of constructive community activities, help to integrate these new, diverse groups and interests.

**Virginia's people: A cultural panorama,** J. B. GITTLER ([*Richmond*]: *Va. State Planning Bd., 1944, pp. 125, illus. 38*).—This is a special report in which the author reviews the economic and cultural development of the people in the State of Virginia.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**George Washington Curtis and Frank Arthur Gulley: Two Early Agricultural Teachers in Texas,** S. W. GEISER (*Field and Lab., 14 (1946), No. 1, pp. 13, illus. 2*).—Biographical accounts are given of these pioneers (E. S. R., 80, p. 287; 93, p. 816), in agricultural education and research.

## FOODS—HUMAN NUTRITION

Index to the literature of food investigation, A. E. GLENNIE and J. L. H. KEUNEMAN ([*Gt. Brit.*] *Dept. Sci. and Indus. Res., Index Lit. Food Invest.*, 16 (1944), No. 1, pp. 74+).—This annotated bibliography to food investigations, classified by subject, continues the series previously noted (E. S. R., 94, p. 677). The literature covered in this issue is chiefly for the period 1941-43 and deals with the following general topics: Meat; pig flesh; poultry and game; fish; eggs; dairy produce; fats and oils; fruit and vegetables; grain products, crops and seeds; theory of canning; theory of freezing and chilling; bacteriology; mycology; engineering; and miscellaneous items.

Tables of representative values of foods commonly used in tropical countries, B. S. PLATT ([*Gt. Brit.*] *Med. Res. Council, Spec. Rpt. Ser.*, No. 253 (1945), pp. 41).—This compilation presents data on the proximate mineral and vitamin content per 100 gm. edible portion of 233 foods, grouped into 12 main categories on the basis of their nutritive value and with consideration to the type of dietary commonly found in tropical countries: (1) Cereals and starchy roots, fruits, etc.; (2) legumes; (3) oilseeds and nuts; (4) vegetables—leafy, green, yellow, and other; (5) fungi and yeasts; (6) fruits; (7) stems; (8) fats and oils; (9) animal products—fish and fish products including Mollusca and Crustacea, insects, meat, meat products, eggs, milk, and milk products (10) condiments and spices; (11) sirups, sugars, and preserves; and (12) beverages. Foods are designated by common English and botanical names, with supplementary information in certain cases on alternative botanical names and native names. Data on Ca and Fe, among the minerals, and vitamin A, thiamine riboflavin, nicotinic acid, and ascorbic acid among the vitamins, are tabulated insofar as figures were available. Calories per 100 gm. edible portion and waste as percentages on the as-purchased basis are also given.

The tables are based on values selected from an extensive literature noted in the bibliography and on unpublished data obtained from analyses of samples collected by the Nyasaland nutrition survey, which is briefly discussed. "An attempt has been made to assess the weight to be attached to the various analyses, and to arrive at representative values for a suitable range of foodstuffs. These values are considered to be sufficiently well founded for the purpose for which they have been compiled, namely, the evaluation of dietary data based on records of group intake. They are not suitable for surveys by the individual method, nor for precise nutritional investigations on individual human and animal subjects. Many of the values are at present only tentative or provisional, and revision will be undertaken from time to time as further data become available."

Facts and recipes for corn meal and grits (*Clemson Agr. Col., S. C., Ext. Cir.* 275 (1946), pp. 20, illus. 3).—This circular combines the material previously presented (E. S. R., 93, p. 509; 94, p. 532).

Fruit granules, W. V. CRUESS, H. F. FRIAR, and T. SHEARING (*Canner*, 102 (1946), No. 16, p. 12).—When mixed with three parts (by weight) of anhydrous dextrose, screened and air-dried, concentrated orange juice of 70°-72° Balling yields a dry, granular product which may be used for candy, additions to dry breakfast cereal, or used in milk shakes, gelatin desserts, cooky and cake batter, and fruit punches.

The nutritive value of canned foods.—VIII, Distribution of proximate and mineral nutrients in the drained and liquid portions of canned vegetables,

A. KRAMER. (Md. Expt. Sta.). (*Jour. Amer. Dietet. Assoc.*, 21 (1945), No. 6, pp. 354-356).—This study forms part of a cooperative project on the nutritive value of canned food (E. S. R., 94, pp. 395-398). Asparagus, green beans, lima beans, beets, carrots, corn, peas, and spinach were analyzed for their proximate and mineral (Ca, P, and Fe) composition. Results varied widely not only among the products but among samples of the same product.

The following generalizations were noted: "The liquid portion rarely exceeds one third of the entire can contents. . . . Any specific nutrient was rarely present in the liquid portion to a greater extent than one-third of its total content in the can. Nutrients insoluble in water remained principally in the solid portions of the foods."

A discussion is presented of the various factors which might be responsible for the results obtained.

Frozen fruits in bulk packages for home use, L. W. ANDERSON and J. D. WINTER (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 2-3, 5, illus. 2).—Commercially frozen blueberries, sweet cherries, apricots and peaches, packed in 20 to 35 lb. containers were repacked into heavily waxed pint containers and placed in home freezer units. Repacking was started when the ice crystals between the fruit defrosted enough for individual pieces to be separated from the original pack, thus eliminating loss of quality in the fruit. Because of the percentage of defects found in the commercially packed fruit, the frozen peaches and apricots were found unsatisfactory for repacking and canning. Blueberries and cherries were found more desirable and convenient to repack. Some of the advantages in using these frozen fruits are noted.

Foods from the freezer precooked or prepared, F. FENTON and J. DARFLER (*N. Y. State Col. Agr., Cornell Ext. Bul. 692* (1946), pp. 100, illus. 20).—The studies incorporated in this publication are one of a series being carried out under the direction of the committee on Frozen Food Research (made up of staff members at Cornell University). The term cooked or precooked is used here to include some foods such as salads, batters, doughs, pies, cookies, biscuits, and rolls which are frozen, prepared, uncooked foods. Foods which are strictly fresh only at certain times of the year, dishes that require long preparation and little more work when prepared in quantity, and dishes that require only slight thawing are good foods for freezing if desired lengths of storage are observed. General information is given regarding preparation (including recipes), packaging, storage temperatures, length of storage, and preparation for the table.

Improvement in the method of cooking certain dehydrated foods, J. R. SPINELLA, C. E. FRENCH, and G. H. BERRYMAN (*Jour. Amer. Dietet. Assoc.*, 21 (1945), No. 3, pp. 148-150).—Studies were made on the following dehydrated foods: Apple nuggets, beets, cabbage, carrots, cranberries, onions, potatoes, sweetpotatoes, and turnips. Reduced ascorbic acid was determined by the method of Loeffler and Ponting (E. S. R., 89, p. 515) and total ascorbic acid by the method of Roe and Kuether (E. S. R., 90, p. 297). Assays were made on the product uncooked, after cooking without preliminary hydration, and after following the recommended procedures of soaking and cooking.

The results are evaluated in terms of palatability, length of preparation time, yield of product, and ascorbic acid content. In general, the one-step method (without hydration) gave superior results including better appearance, texture, and palatability; considerable shortening in the time of preparation; and better retention of ascorbic acid.

With the exceptions of beets and cranberries, which gave a 10 to 20 per cent lower yield of the cooked drained product by the one-step method, the yields for the other dehydrated foods were comparable in both methods of cooking.

**Food consumption levels in the United States, Canada, and the United Kingdom.** K. JACOBSON, J. N. LEWIS, I. S. MCARTHUR, L. B. PETT, P. G. H. BARTER, and W. D. S. JONES (*U. S. Dept. Agr., Prod. and Market. Admin., 1946, pp. 58+, illus. 7*).—This third report to the Combined Food Board on food consumption levels in the United States, Canada, and the United Kingdom is a revision of statistical material included in the second report (E. S. R., 92, p. 859). The changes between 1944 and 1945 are reviewed, and comparisons are given for civilian supplies before the war and during war years. Special attention is given to the recapitulation of the three countries from the prewar period, 1935-39, up to 1945. The per capita food supplies are shown in tabular form, and include commodities as well as nutrients.

**The impact of the war on civilian consumption in the United Kingdom, the United States, and Canada.** M. A. COPELAND, E. ROSS, J. F. PARKINSON, R. W. JAMES, H. CAMPION, and R. G. D. ALLEN (*Washington 25, D. C.: Govt., 1945, pp. 157+*).—This is a report to the Combined Production and Resources Board from a special Combined Committee on Nonfood Consumption Levels. Objective measurements affording a basis for comparisons between these countries are proposed. Pertaining to the physical volume of goods and services obtained by civilians, a portion of this study is devoted to the restrictions and alterations of the character of consumption. Analyses are made in detail on the extent to which consumption of different items has been changed as a result of the war.

**Nutritional status of midwestern college women.** E. G. DONELSON, P. M. NELSON, M. A. OHLSON, M. S. PITTMAN, R. M. LEVERTON, H. MCKAY, G. M. KINSMAN, W. ARMSTRONG, and M. S. REYNOLDS. (Minn., Iowa, Kans., Nebr., Ohio, Okla., and Wis. Expt. Stas.). (*Jour. Amer. Dietet. Assoc., 21, (1945), No. 3, pp. 145-147*).—Nutritional status studies covering a 6-yr. period (1936-42) were carried out as a joint project in seven Midwestern States. Identical methods and procedures were followed at all cooperating institutions. Separate parts of the study have been published periodically (E. S. R., 93, p. 95), and the general results obtained in the various studies are here tabulated and discussed.

The data show that the mean values for height and weight are 163.7 cm. and 57.1 kg., respectively. Basal metabolism results vary with locality (climate). In Kansas and Oklahoma, with a warmer climate, the values were somewhat lower than in the other States (33.0-33.1 v. 34.1-34.9 calories per square meter per hour). All values were lower than the theoretical standards for young women (36.9-37.4 calories per square meter per hour). Average values for blood constituents were found to be: Hemoglobin 13.4 gm. per 100 cc.; red cell count 4.56 millions per cubic millimeter; hematocrit 40.9 percent; and plasma ascorbic acid 0.66 mg. per 100 cc.

A qualitative assessment of the diets revealed a notable lack in the amount of citrus fruits and tomatoes used, and an inadequate intake of green and yellow vegetables, and milk. Although the number of students eating whole grain products was low, it was anticipated that the bread enrichment program would have offset this to a degree.

"The mean calorie value of the self-selective, weighed diets of a group of 58 women was approximately 2,000 calories per capita. From the metabolic balance studies performed, the authors conclude that 1 gm. calcium daily

might well be recommended at ages 17 to 24 yr. and that 1 gm. phosphorus and 56 gm. protein are necessary to maintain equilibrium. In the case of iron, it was found that the adequacy of the remainder of the diet is of signal importance and that with a good diet an intake of only 7.21 mg. iron daily is sufficient."

**School lunches:** A list of references, C. L. FELDKAMP and M. K. SILVER (*U. S. Dept. Agr., Libr. List 26 (1946), pp. 66*).—This extensive annotated bibliography with index contains 528 selected references on the subject of school feeding in the United States during the years 1925 through 1945. It includes references on lunchroom management, the use of the school lunch as a means of training and education, nutrition aspects, lunch programs, and the preparation, serving, and popularizing of balanced lunches. References on the home-prepared lunch have been omitted, as have references on the nutrition of school children unless they deal with school feeding. Sources consulted are noted, and such references cited as are available carry the call numbers of the U. S. D. A. Library.

**Some effects of a white corn meal shortage,** D. DICKINS. (*Miss. Expt. Sta.*). (*Jour. Amer. Dietet. Assoc., 21 (1945), No. 5, pp. 287-288*).—Data were obtained from questionnaires filled out by 1,404 white and Negro children in 12 junior high schools in Mississippi as to the influence of a shortage of white corn meal upon the food habits of the groups studied. Tabulated results indicate the relative consumption of 18 foods when accompanied by white corn bread, yellow corn bread, or biscuit. In the absence of white corn meal, a large proportion of the families questioned either made no corn bread (8-12 percent) or made corn bread only a few times with yellow corn meal (43-61 percent).

The consumption of buttermilk and the strong-flavored, green leafy vegetables, such as turnip greens, collards, and cabbage was greatly reduced when the use of corn bread was limited by the shortage of the white corn meal (which was preferred by over 61 percent of those questioned).

The author stresses the point that the superior nutritive value of yellow corn meal over white corn meal may be offset by the fixed food habits of the population. Reduced consumption of other foods (greens and buttermilk) occurs when the quantity of the favorite kind of corn bread is limited.

**Observations on the growth-stimulating action of certain proteins added to protein-free diets compounded with amino acids,** D. W. WOOLLEY (*Jour. Biol. Chem., 159 (1945), No. 3, pp. 753-754*).—Mice fed acid-hydrolyzed casein (18 percent) as the source of N in their diet grew at a suboptimal rate even when cystine and tryptophan were added to the diet. Small amounts of intact casein or crystalline trypsinogen were necessary for the restoration of normal growth. Coagulated egg white was ineffective.

Streptogenin (an unidentified peptide-like bacterial growth factor) was prepared from a tryptic digest of casein and fed at a level equivalent to the minimal effective dose of intact casein. At this level (equivalent to 2 percent casein), normal growth was restored. The activity of the streptogenin was destroyed by acid hydrolysis.

The author stresses the point that "for mice, as well as for bacteria, the nutritional properties of proteins are not related solely to the amino acids obtainable by acid hydrolysis."

**Nutritional value of yeast protein to the rat and the chick,** A. A. KLOSE and H. L. FEVOLD. (*U. S. D. A.*). (*Jour. Nutr., 29 (1945), No. 6, pp. 421-430*).—Brewers' yeast and torula yeast grown on molasses were fed to

rats as the protein supplement to an adequate basal diet. The same yeasts, as well as a torula yeast grown on prune juice, were tested on chicks.

Previous experiments (E. S. R., 93, p. 97) on the nutritive value of yeast protein for rats were confirmed; similar results were observed with chicks.

The experiments demonstrated that, at the levels fed, yeast protein produced growth inferior to that produced by equivalent amounts of casein. With rats, the level of crude protein was approximately 13.3 percent (based on the factor  $N \times 6.25$ ). The addition of 0.5 percent methionine to the yeast diet of rats or chicks increased the growth rate so that it became comparable to that obtained with casein. The inclusion of 0.5 percent of *L*-cystine further increased the efficiency of the yeast diet.

No toxic effects were noted when yeasts were fed at relatively high levels (approximately 40 percent of the diet) over a limited period of time.

The authors conclude that the inadequacies of yeast protein can be corrected by the addition of methionine or methionine-rich protein to the diet.

The relation between absorbed nitrogen, nitrogen balance, and biological value of proteins in adult dogs, J. B. ALLISON and J. A. ANDERSON. (Rutgers Univ.). (*Jour. Nutr.*, 29 (1945), No. 6, pp. 413-420, illus. 2).—Based on nitrogen equilibrium studies made on normal adult dogs, formulas are presented showing the relationship between nitrogen balance (NB), absorbed nitrogen (AN), urinary nitrogen (UN), and biological value (BV).

The relationship between NB and AN was found to be linear in the region of negative NB, becoming obviously curvilinear well on the positive side of NB.

The biological value (BV) of the protein of the foods tested was found to be casein = 0.82, chicken entrails = 0.77, flounder entrails = 0.77, flounder heads = 0.52, and a protein derived from soybean = 0.39.

A dietary factor essential for guinea pigs.—VII, Changes in the distribution of the plasma protein during the deficiency, W. J. VAN WAGTENDONK and L. P. ZILL. (Oreg. State Col.). (*Jour. Biol. Chem.*, 159 (1945), No. 2, pp. 247-253).—Guinea pigs fed a diet deficient in the antistiffness factor (E. S. R., 93, pp. 512-514) exhibited significant changes in the distribution of plasma protein. Total plasma nitrogen was raised, primarily due to an increase in globulin nitrogen. Albumin nitrogen was found to decrease. As a result, the albumin-globulin ratio was disturbed, becoming much lower (0.35 to 0.65) in the deficient guinea pigs than in normal ones (normal ratio about 1.00 to 1.18).

The implications of the changes observed are discussed.

The protein requirements of adult human subjects in terms of the protein contained in individual foods and food combinations, M. BRICKER, H. H. MITCHELL, and G. M. KINSMAN. (Univ. Ill.). (*Jour. Nutr.*, 30 (1945), No. 4, pp. 269-283, illus. 1).—Nine college women served as subjects. A basal diet consisting of sugar-cornstarch-lard cookies supplemented with sucrose, lactose, fondant, jelly, butterfat, lemon juice, apple sauce, lettuce, and French dressing furnished from 0.14 to 0.23 gm. of nitrogen daily. Supplements of minerals and vitamins were added. Test foods, fed in amounts needed to maintain body weight, were able to supply 91 percent or more of the total N ingested.

The protein foods tested were soya flour, patent white flour, milk, a soya-white flour mixture containing 13 percent soya flour, and a well-balanced mixture of normally consumed foods (oatmeal, egg, milk, beef, potatoes, biscuits, etc.). "All test foods . . . were cooked in some appropriate manner if they are commonly prepared by cooking." Each food was studied at

several levels of N intake to determine the relationship existing between N intake and N balance.

"For milk, white flour, soya flour, the soya-white flour combination, and the mixed foods, the indicated biological values were, respectively, 74, 41, 65, 55 and 65 percent, and the amounts of nitrogen required for equilibrium (as ordinarily measured) were, respectively 2.76, 4.76, 2.88, 3.38, and 3.12 mg. per basal calorie." True digestibility for the same foods was calculated to be 94, 97, 92, 94, and 90 percent, respectively.

One subject, on the white flour diet, was found to be in negative N balance. Supplementation with small amounts of lysine produced a positive N balance, indicating the need of this amino acid by the adult human for nitrogen equilibrium.

**The utilization of d-amino acids by man, III-IV** (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 25-31, illus. 2).—A continuation of the series (E. S. R., 95, p. 128).

III. *Arginine*, A. A. Albanese, V. Irby, and J. E. Frankston (pp. 25-30).—Studies were made of the output of N metabolites, urea, amino N, and arginine in particular, following the administration of equal quantities of *l*(+)- and *dl*-arginine. Results indicate that the *d* form is catabolized in the human. Experimental support arises from the in vitro finding that crude arginase prepared from human liver yields stoichiometric equivalents of urea from both *d*(-)- and *l*(+)-arginine. Experiments with rat liver preparations showed a lack of arginase activity with respect to *d*(-)-arginine.

IV. *Acetyltryptophane*, A. A. Albanese, J. E. Frankston, and V. Irby (pp. 31-34).—Studies on human metabolism showed that the urinary excretion of the *d* component of acetyl-*dl*-tryptophan, unlike that of *dl*-tryptophan, does not differ qualitatively from that of the *l* component. Measurements of the urinary output of indole metabolites following the administration of acetyl-*l*(-)- and acetyl-*dl*-tryptophan indicated greater utilization of acetyl-*d*-tryptophan in man than of *d*-tryptophan. The significance of these observations to human nutrition is discussed.

**A study of hemoglobin formation following the administration of certain amino acids to rats fed a diet low in protein**, A. U. and J. M. ORTEN (*Jour. Nutr.*, 30 (1945), No. 2, pp. 137-142).—Weanling female rats were fed a low-protein diet (lactalbumin 3.5 percent) which was found to produce a chronic anemia. Supplements with 15 individual amino acids in amounts comparable to that found in 18 percent lactalbumin produced no consistent increase on the hemoglobin content of the blood of the rats. Controls on the initial 3.5 percent protein level showed normal hemoglobin values after 6 weeks supplementation with adequate amounts of lactalbumin.

The authors interpret the results "as evidence that no single amino acid can be regarded as a 'key' amino acid in hemoglobin synthesis in the organism, but rather that a combination of amino acids in as yet undetermined proportions is essential for the in vivo fabrication of the hemoglobin molecule."

**Tryptophane utilization and synthesis by strains of *Lactobacillus arabinosus***, L. D. WRIGHT and H. R. SKEGGS (*Jour. Biol. Chem.*, 159 (1945), No. 3, pp. 611-616, illus. 4).—By the use of daily transplants in media low or lacking in tryptophan, strains of *L. arabinosus* were developed which grew abundantly without the addition of tryptophan, indole, or anthranilic acid. When grown in the presence of tryptophan, the altered strain produced tryptophan in an amount inversely proportional to that added to the media.

The authors stress the fact that the nutritional requirements of micro-organisms may be influenced appreciably by differences in the methods of handling.

The effects of the dietary supply of carbohydrate upon the response of the human respiratory quotient after glucose administration, H. F. ROOT and T. M. CARPENTER (*Jour. Nutr.*, 30 (1945), No. 5, pp. 333-341).—For periods lasting several days, two medical students were fed diets containing 350, 75, or approximately 11 mg. of carbohydrate per day. Basal respiratory quotient (R. Q.) was measured on alternate days and, after the ingestion of 50 mg. glucose, the R. Q.'s were determined at 15-min. intervals over a 3-hr. period.

Calculated by the usual empirical formula, the basal combustion of carbohydrate (estimated to 3 hr.) averaged 12.0 and 13.4, 6.1 and 7.1, 0 and 2.1 gm. for subjects A and B on the three dietary levels, respectively. Similarly, the increase in combustion of carbohydrate after ingestion of 50 gm. of glucose was 14.0 and 8.7 at the 350-gm. level, 8.7 and 5.9 at the intermediate level, and 7.9 and 4.8 gm. at the low level of dietary carbohydrate.

The authors conclude from their observations that "the level of carbohydrates in the preceding diet affected the basal combustion of carbohydrates noticeably, and to some extent the increases in carbohydrate combustion after ingestion of glucose, but not so much as one would expect when the demand for replacement of glycogen supply is considered."

The effect of various adjuvants to the diet of rats on the changes in body fats induced by feeding soybean oil, J. A. SCHULZ and B. H. THOMAS (*Iowa Sta. Res. Bul.* 336 (1945), pp. 625-647).—Fourteen lots of six rats each were fed a basal ration composed of 50 percent solvent process soybean oil meal, 2 percent yeast, 1.5 percent salts, 10 percent soybean oil, codliver oil concentrate, and sugar to make a total of 100 percent. Thirteen adjuvants affecting the fat metabolism were added to the diet. Of these carotene, bile salts, agar-agar, sodium flouride, and calcium chloride probably induced the deposition of fats with lower iodine values.

In a second experiment, six lots of seven rats each were fed approximately the same diet as noted above except that starch replaced the sugar. Three levels of carotene or 1 percent levels of choline chloride or nicotinic acid were added to this diet as supplements. There was no evidence from the results obtained that these supplements influenced consistently the hardness of the deposited body fat.

The dietary production of fatty livers resistant to the action of choline, M. L. MACFARLAND and E. W. MCHENRY (*Jour. Biol. Chem.*, 159 (1945), No. 3, pp. 605-609).—Previous studies by Gavin and McHenry on the effect of B vitamins on fat metabolism (*E. S. R.*, 88, p. 555) have been elaborated. Rats were depleted of fat by being fed a fat-free, B vitamin-free basal diet for 3 weeks. Supplements of certain B vitamins, when fed with a beef-liver fraction (1), or with biotin (2), caused the production of fatty livers and an increase in the cholesterol content of the liver. The addition of choline to the diet had no effect on the fatty livers produced by (1), but markedly reduced the fatty acid content of the fatty livers induced by (2). The addition of inositol to the diet was effective in reducing liver fat to a low level in (1) with or without the addition of choline to the diet. In biotin-induced fatty livers, inositol alone was partially active and, with the addition of choline, completely effective in preventing the formation of fatty livers.

The effect of cocoa on the utilization of dietary calcium, H. H. MITCHELL and J. M. SMITH. (Univ. Ill.). (*Jour. Amer. Med. Assoc.*, 129 (1945), No. 13, pp. 871-873).—"In the growing rat, two medium cost cocoas containing about 22 percent of fat depressed the utilization of calcium in proportion

to their content of oxalic acid. A low cost cocoa containing about 11 percent fat and apparently appreciably more cacao shell depressed growth more than the higher grade cocoas, and depressed calcium retention about twice as much as can be accounted for by its content of oxalic acid.

"In adult human subjects, whether subsisting on a low calcium diet or on diets of borderline calcium adequacy, a medium cost cocoa in daily portions of 21 to 38 gm., approximating the tolerance limit, was not shown to affect the calcium balance adversely.

"However, if the effect of such cocoas on calcium utilization resides entirely in their content of oxalic acid, as the rat experiments indicate, it would not be expected to be appreciable in human metabolism, because the oxalic acid content of cocoa is only moderate, i. e., 0.5 to 0.6 percent, and the calcium in the cocoa itself is sufficient to combine with about two-thirds of the oxalic acid. Furthermore, the immobilization of milk calcium in the digestive tract by the remaining third of the oxalic acid of cocoa, equivalent to 22 mg. of calcium for a 1-oz. portion of cocoa, would be expected to depress calcium retention by only one-fifth of this amount (4 or 5 mg. of calcium), because of the poor utilization of calcium (19 percent or so) by the adult human organism. Such a small depression in calcium retention is practically impossible to detect by the technic of the metabolism experiment with human subjects. . . ."

Calcium metabolism of preschool children. E. K. WATSON, E. W. MCGUIRE, F. L. MEYER, and M. L. HATHAWAY. (Cornell Univ.). (*Jour. Nutr.* 30 (1945), No. 4, pp. 259-268).—The present data form part of a comprehensive study on the influence of variation in the ascorbic acid and citrate content of the diet upon the ascorbic acid, citric acid, Ca, P, and N metabolism of eight preschool children (E. S. R., 95, p. 129).

Calcium intake averaged 1,122 mg. per day for half of the subjects and 775 mg. per day for the remainder. Basal diets were supplemented with ascorbic acid, potassium citrate, or orange juice.

Results, tabulated in detail, indicate that calcium retentions (during 16 weeks' test) averaged  $131 \pm 50$  mg. on the higher level and  $96 \pm 25$  mg. on the lower level of intake. Addition of ascorbic acid or orange juice to the basal diet produced no significant increase or change in the calcium retention. The addition of 3.38 gm. of potassium citrate lowered the urinary excretion of calcium in all eight subjects but did not alter the level of calcium retention.

As the absorption of calcium did not seem to be in the main factor regulating its retention in at least five of the children tested, it is concluded that "factors other than diet alone regulated the calcium retention during the 16 weeks of observation."

The availability of the iron in Hawaiian-grown vegetables. C. D. MILLER and L. LOUIS. (Hawaii Expt. Sta.). (*Jour. Nutr.*, 30 (1945), No. 6, pp. 485-494, illus. 1).—The iron content of 15 vegetables and 2 seaweeds grown in Hawaii was determined by the chemical method with ortho-phenanthroline using a photoelectric colorimeter. The availability of the iron was determined by its ability to regenerate hemoglobin in anemic rats. Comparisons were made with control groups fed pure ferric chloride. Supplements of Cu and Mn were fed to all the animals.

Considering the utilization of the iron in  $\text{FeCl}_3$  as 100, the availability of the iron from the various foods was as follows: "Green soybeans 96, taro corms 93, taro leaves 93, fresh lima beans 74, cowpeas (pods) 65, a seaweed, limu lipoa (*Haliseris plagiogramma*) 62, swamp cabbage (*Ipomoea aquatica*)

59, broccoli 52, green snap beans 49, white mustard cabbage (*Brassica chinensis*) 34, amaranth (*Amaranthus gangeticus*) 32, watercress 31, belembé (*Xathosoma brasiliense*) 31, carrots 17, green mustard cabbage (*Brassica juncea*) 10, and asparagus 6."

"The superior quality of the iron of legume seeds for hemoglobin regeneration in the rat was confirmed. Taro corms and taro leaves, both important items in the diet of the Polynesians, were shown to have a high percentage of available iron.

"The percentage of the food iron soluble in dilute acetic or in dilute sulphuric acid bore no relationship to the availability as determined by bioassay."

**Comparative effectiveness of various iron compounds in promoting iron retention and hemoglobin regeneration by anemic rats, S. FREEMAN and M. W. BURRILL** (*Jour. Nutr.*, 30 (1945), No. 4, pp. 293-300).—Anemic rats were fed various compounds of iron as iron salts or in bread. No differences in qualitative or quantitative retention were found due to the method of feeding.

The effectiveness of the various iron compounds with respect to the relative degree of iron retention and hemoglobin regeneration in anemic rats was as follows: Ferric chloride > sodium ferric orthophosphate = ferric phosphate > reduced iron > sodium iron pyrophosphate.

Anemia was prevented in milk-fed rats by feeding supplements of ferric chloride or sodium iron pyrophosphate for 40 days after weaning. Iron retention and hemoglobin regeneration in these animals were comparable to results obtained with depleted (anemic) rats fed the same supplements for 28 days.

**The availability of soybean oil meal phosphorus for the rat, R. R. SPITZER and P. H. PHILLIPS.** (Wis. Expt. Sta.). (*Jour. Nutr.*, 30 (1945), No. 2, pp. 117-126, illus. 2).—Weanling rats were fed a semi-synthetic diet containing 14 percent fibrin and a low-calcium low-phosphorus salt mixture as a basal ration. The ration furnished 0.28 percent phosphorus and was supplemented with either  $\text{CaHPO}_4$  or  $\text{CaCO}_3$  to provide approximately 0.6 percent calcium. Additions of various amounts of inorganic phosphorus (up to 0.3 percent) were made in connection with the basal diet. Substitution of the 14 percent fibrin with equivalent amounts of casein (14 percent) or soybean oil meal in amounts to provide 14 percent protein was also made.

Results showed that the blood fibrin ration used was an excellent low phosphorus ration, as adequate growth and bone formation occurred in young rats when proper supplements of phosphorus were added. Soybean oil meals prepared by the expeller or solvent process were found to contain 0.66 percent P, of which 58 percent was in the form of phytin or phytic acid. Results showed that the phosphorus of soybean oil meal was readily available for growth and bone formation. Additional heat apparently had no measurable effect on the availability of the phosphorus. The phosphorus of casein was also readily available. Regardless of the level of phosphorus ingested the bone ash contained approximately 18 percent phosphorus.

The protein of soybean oil was practically equal to that of blood fibrin, and both of these proteins proved superior to casein when used at the 14 percent level.

**Enzymatic relationships in the utilization of soybean oil meal phosphorus by the rat, R. R. SPITZER and P. H. PHILLIPS.** (Wis. Expt. Sta.). (*Jour. Nutr.*, 30 (1945), No. 3, pp. 183-192, illus. 2).—In continuation of the study

noted above, weanling rats were fed a similar diet with the exception that a 1 per cent 1 : 20 liver powder was omitted.

In certain experiments, the entire ration, or the soybean oil meal fraction, was heated at 98° C. for 48 hr. in an attempt to destroy any possible phytase present. Neither the removal of the liver powder supplement nor the use of heat-treated rations affected the availability of the phosphorus present. The utilization of soybean oil meal P was considered to be independent of any ration-borne heat-labile phytase.

A method was devised for the estimation of phytase activity and used to analyze samples of rat, chicken, pig, and cow intestines. Results showed that the small intestinal mucosa and the intestinal contents of the rat possessed phytase activity, as did the intestinal mucosa of the other species studied. The optimum pH for the enzyme was 7.8. Soybean oil meal showed no phytase activity at either pH 5.2 or 7.8.

The authors conclude that "from these studies it would appear that the phytin or phytic acid phosphorus of soybean oil meal was made available by the action of intestinal phytases."

**Vitamin A and carotene in the nutrition of the guinea pig, L. S. BENTLEY and A. F. MORGAN.** (Univ. Calif.). (*Jour. Nutr.*, 30 (1945), No. 3, pp. 159-168, illus. 1).—Guinea pigs were maintained on a semi-purified diet composed as follows: Casein 25, cornstarch 40, hydrogenated cottonseed oil 3.5, salt mixture 4, K<sub>2</sub>CO<sub>3</sub> 0.5, wheat germ 10, yeast 10, and bran 7. This was supplemented three times a week with 6 cc. lemon juice (containing 6 mg. ascorbic acid). With the addition of an adequate amount of carotene or vitamin A, normal growth of young guinea pigs was obtained.

To produce a diet low in vitamin A, the casein was extracted with hot alcohol. In the absence of added vitamin A, this diet produced deficiency symptoms and death within 3-4 weeks. Xerophthalmia and loss of weight were the principal deficiency symptoms noted.

After being fed known amounts of carotene or vitamin A, certain guinea pigs were sacrificed and carcass and tissue analyses made. Results indicated that storage of vitamin A occurred primarily in the liver—traces being found in the kidney. Liver stores were low except when preformed vitamin A was fed. Vitamin A seemed to be approximately six times more effective than carotene in building up liver stores of the vitamin. When sources of vitamin A were removed from the diet, rapid loss of the amount stored in the liver was noted—90 percent disappearing within 30 days.

Preliminary experiments were made to determine the relative importance of carotene and vitamin A upon reproduction in guinea pigs. Results indicated that vitamin A might be superior to carotene in this respect.

**Relative value of carotene in vegetables for growth of the white rat, A. R. KEMMERER and G. S. FRAPS.** (Tex. Expt. Sta.). (*Arch. Biochem.*, 8 (1945), No. 2, pp. 197-201).—The  $\beta$ -carotene equivalent of 27 samples of raw, cooked, or canned foods or feeds was tested by rat growth in comparison with the  $\beta$ -carotene equivalent of purified carotene in cottonseed oil. The foods studied were alfalfa, apricots, beet greens, carrots, collards, mustard greens, pumpkin, spinach, sweet potatoes, Swiss chard, and turnip greens. With the exception of beet greens and carrots, in which the values were respectively 80 and 64 percent of that of pure carotene, the carotene in the remaining foods was practically as well utilized as the carotene in oil. Average relative values ranged from 94 percent for collards to 109 for alfalfa. However, wide ranges occurred with different samples of the same food (sweetpotatoes ranged from 70 to 116 percent).

The value of 1 $\gamma$  of pure carotene ranged from 0.8 to 2.4 U. S. P. units (average 1.4) in 20 dried foods or feeds tested. The  $\beta$ -carotene equivalent of these foods was not calculated. The authors conclude from these experiments that "at a low level of feeding, sufficient for moderate growth, the vitamin A value of the  $\beta$ -carotene equivalent in plant materials appears to be equal to that of  $\beta$ -carotene dissolved in cottonseed oil."

**Physiological availability to the rat of crude carotene in vegetables,** B. L. OSER and D. MELNICK (*Jour. Nutr.*, 30 (1945), No. 5, pp. 385-389).—A number of canned vegetables and fruits were studied in an attempt to correlate crude carotene content, determined colorimetrically, with the vitamin A potency determined biologically.

A photometric adaptation of the A. O. A. C. colorimetric procedure was used; xanthophylls and lycopene being removed by extraction or adsorption. In the rat bioassay technic, mixed tocopherols were fed at a level of 0.5 mg. per day in order to eliminate them as variables in the test.

The canned vegetables tested were carrots, kale, Swiss chard, mixed greens, pumpkin, spinach, squash, tomato products, and vegetable soups. In these products, 1.0  $\mu$ g. of crude carotene (free from xanthophyll and lycopene) was equivalent to 1 U. S. P. unit of vitamin A. No great differences were observed in the physiological availability of the carotene in most of the vegetables tested. Prunes, peach puree, and an apricot-apple mixture were also assayed. In the last two products, the bioassay values were three to six times higher than the colorimetric analyses. The authors indicate that in some fruit products the crude carotene content may be a poor index of vitamin A potency. Various reasons for this discrepancy are suggested.

**Availability of carotene from kale,** E. ORENT-KEILES, E. C. CALLISON, J. SCHAEVITZ, and R. FRENCHMAN. (U. S. D. A.). (*Science*, 103 (1946), No. 2678, pp. 498-499).—Comprehensive experiments were made on 18 lots of steam-cooked kale. The leaf blades were divided in two (excluding midrib or petiole), and half were assayed biologically. The other half were used in preparing extracts which were assayed both biologically and chemically.

"The chlorophylls and xanthophylls were removed by saponification with potassium hydroxide, leaving the carotenoid pigments in the solution. Aliquots were taken from the extract for chromatographing and determining  $\beta$ -carotene spectrophotometrically; the remaining extract was concentrated in cottonseed oil containing hydroquinone and was analyzed biologically."

The biological assays followed the recommended U. S. P. method in which pure  $\beta$ -carotene in cottonseed oil was used as the reference standard.

Results showed the cooked kale to assay 90 International Units per gram by chemical analysis, and 60 I. U. per gram by bioassay. The biological assay value obtained on the extract of cooked kale was 84 I. U. per gram.

The authors suggest that incomplete digestion and consequent incomplete absorption of the vegetable carotene in the digestive tract may be an important factor in differences in the vitamin A values for kale obtained by chemical and biological methods.

**Bodily storage of vitamin A in relation to diet and age, studied by the assay method of single feedings,** H. L. CAMPBELL, M. UDILJAK, H. YARMOLINSKY, and H. C. SHERMAN (*Jour. Nutr.*, 30 (1945), No. 5, pp. 343-348).—Young rats were fed an adequate diet containing 3, 6, or 12 International Units of vitamin A per gram of air-dry food. The offspring of the original animals, maintained on the same diet, were sacrificed after 30, 60, 90, 150, 225, or 300 days, and the vitamin A content of their livers determined by the single feeding technic.

Results showed that at the lower level of intake (3 I. U. per gram) negligible storage of vitamin A occurred in the liver. With increased intake of vitamin A, larger stores were found both per gram of liver and in total amount stored. At the 12-I. U. level, the body stores increased progressively throughout the range of the experiment. At the 6-I. U. level, a decrease in the rate of storage was noted at about 90 days.

The actual efficiency of storage was found to be about 10 to 30 percent of the theoretically available surplus ingested in the food.

**Bodily storage of vitamin A in relation to diet and age studied by means of the antimony trichloride reaction using a photoelectric colorimeter, A. B. CALDWELL, G. MACLEOD, and H. C. SHERMAN** (*Jour. Nutr.*, 30 (1945), No. 5, pp. 349-353).—The livers of the animals described above were also assayed for vitamin A by the chemical antimony trichloride method using a photoelectric colorimeter. The results were substantially in agreement with those obtained by the single feeding technic.

The authors note that "at a level of intake of 8 International Units per gram there was very little storage of the vitamin and no increase in storage with increasing age up to 300 days. The vitamin A value of 3 I. U. per gram is not optimal, and in the light of these storage results appears to be near the minimal limit of adequacy."

**Retention of B vitamins in oatmeal during cooking, J. M. COOPERMAN and C. A. ELVEIHEM.** (Wis. Expt. Sta.). (*Jour. Amer. Dietet. Assoc.*, 21 (1945), No. 3, pp. 155-156).—Regular (large flake) and quick (small flake) oatmeal were cooked for varying lengths of time (2½ min.-2 hr.) in single or double boilers and assayed for four B vitamins. No loss of pantothenic acid, riboflavin, or niacin occurred during cooking, variations of  $\pm 5$  percent being considered within the limits of error of the methods of assay.

When the cooking time exceeded 30 min., losses of thiamine were noted. Three methods were used in calculating vitamin loss—(1) by the total change in the amount of vitamin present before and after cooking, based on aliquots of the raw and cooked product and the initial and final weights; (2) by dry weight determinations; and (3) by assaying the vitamin present in a small sample (20 gm.) cooked experimentally. Thiamine losses for quick oatmeal after cooking 30, 60, and 120 min., respectively, amounted to 8, 11, and 14 percent calculated by method 1; 18, 18, and 20 percent by method 2; and 2, 5, and 8 percent by method 3.

The authors conclude that no significant losses occur when oatmeal is cooked 30 min. or less. The total change method (1) is considered best for determining the retention of vitamins during cooking.

**Studies on the requirements of the monkey for riboflavin and a new factor found in liver, J. M. COOPERMAN, H. A. WAISMAN, K. B. MCCALL, and C. A. ELVEIHEM.** (Wis. Expt. Sta.). (*Jour. Nutr.*, 30 (1945), No. 1, pp. 45-57, illus. 3).—In a continuation of the study of Waisman et al. (*E. S. R.*, 91, p. 772) on the nutritional requirements of the monkey, the methods and technics previously described were used. Riboflavin-deficient monkeys developing a typical hypochromic normocytic anemia did not return to normal when adequate riboflavin was fed. The addition of iron, "pseudopyridoxine," 1 : 20 liver powder, extracted liver residue, and additional casein were also unsuccessful in establishing a normal blood picture or normal growth. Whole liver substance at a level of 3 percent of the ration was necessary for optimum growth and blood regeneration. The factor (or factors) present in whole liver seemed to be labile, and different from the *Lactobacillus casei* factor. Twenty-two references are listed.

**Further studies on the monkey anti-anemia factor, J. M. COOPERMAN, K. B. MCCALL, and C. A. ELVEHJEM.** (Wis. Expt. Sta.). (*Science*, 102 (1945), No. 2660, pp. 645-646).—Further experiments on the factor described above have shown that fresh beef and pool liver are more potent sources than whole liver powder. Lyophilized liver was as potent as fresh liver, indicating that no destruction was caused by freezing or drying under vacuum.

**The effects of light, trauma, riboflavin, and ariboflavinosis on the production of corneal vascularity and on healing of corneal lesions, O. H. LOWRY and O. A. BESSEY** (*Jour. Nutr.*, 30 (1945), No. 4, pp. 285-292).—Injury of the cornea was artificially produced in rats which were maintained on diets containing normal, low, or high levels of riboflavin. Corneal trauma was effected by one of three methods: Mechanical, by removal of the epithelium; chemical, by treating with 5 N HNO<sub>3</sub> for 15 sec.; and physical, by exposing to ultraviolet light. The rats were then subdivided into groups which were kept under continuous light or in darkness.

Results showed that brilliant continuous illumination with incandescent lamps did not alter the changes in the cornea and conjunctiva resulting from riboflavin deficiency.

The healing of the injured cornea resulting from ultraviolet light was retarded by brilliant continuous illumination from incandescent lamps and by protracted riboflavin deficiency. Neither visible nor ultraviolet light affected the riboflavin content of the cornea, indicating that this reaction is not the result of local destruction of riboflavin by light but due to some other cause. The healing of injury due to milder trauma (that involving primarily the epithelium) was not affected by either light or riboflavin deficiency alone under the conditions of these experiments. However, a combination of these two factors did lead to definite handicaps.

In a normally nourished rat colony, high riboflavin intake failed to prevent the occurrence of "spontaneous corneal vascularity."

Because of the variety of agents and deficiencies which can induce corneal vascularization, the authors indicate the need for caution in interpretation of corneal vascularization in man.

**Alcohol metabolism as related to the production of thiamine deficiency, W. W. WESTERFELD and E. A. DOISY, JR.** (*Jour. Nutr.*, 30 (1945), No. 2, pp. 127-136).—Pigeons were fed four different thiamine-deficient diets. Alcohol was used to replace either fat or carbohydrate in calorically equivalent amounts. The diets used were: (1) Low fat (4 gm.), high sucrose (51 gm.), and no alcohol; (2) fat 4 gm., sucrose 34 gm., and alcohol 9 gm.; (3) fat 20 gm., sucrose 15 gm., and no alcohol; and (4) fat 13 gm., sucrose 15 gm., and alcohol 9 gm. On these thiamine-deficient diets, the isocaloric substitution of alcohol for either fat or carbohydrate delayed the onset of acute deficiency symptoms (opisthotonus) and death in pigeons. A discussion presents the possible reasons for this sparing action of alcohol. Twenty-seven references are included.

**The excretion of "folic acid" through the skin and in the urine of normal individuals, B. C. JOHNSON, T. S. HAMILTON, and H. H. MITCHELL.** (Univ. Ill.). (*Jour. Biol. Chem.*, 159 (1945), No. 2, pp. 425-429).—Excretion studies were carried out for two 5-day periods on four adult male subjects. During the tests, these men lived for 8 hr. per day under hot moist conditions (37.7° C. and 70 percent relative humidity). A constant diet was maintained throughout the experiment, the diet during the second period being supplemented with brewers' yeast containing 5.5  $\mu$  of added free folic acid.

Assays of urine and sweat were made by both the *Lactobacillus* method (E. S. R., 90, p. 298) and the *Streptococcus lactis* method (E. S. R., 92, p. 760). Results by both methods indicated that under conditions of profuse sweating about five to six times more active folic acid was excreted in sweat than in urine.

The incubation of urine with "vitamin B<sub>9</sub> conjugase" did not result in the liberation of additional folic acid.

**The metabolism of pantothenic acid and its lactone moiety in man.** H. P. SARETT. (Oreg. State Col.). (*Jour. Biol. Chem.*, 159 (1945), No. 2, pp. 321-325).—The *Lactobacillus arabinosus* method (E. S. R., 93, p. 536) and the *Acetobacter suboxydans* test (E. S. R., 94, p. 429) were used to assay pantothenic acid and its lactone moiety, respectively. The urinary excretion of these compounds was measured in three normal subjects after normal diets had been eaten and after oral and intravenous administration of pantothenic acid and the lactone or dihydroxy acid moieties.

Normal excretion of pantothenic acid was found to be about 3.5 mg. per day, this amount accounting for the total lactone present.

Oral or intravenous doses of lactone and intravenous doses of dihydroxy acid were recovered completely in the urine. After oral doses of the dihydroxy acid, only 80 percent was found in two of the urine samples. After 50 mg. oral doses of both moieties, the pantothenic acid excretion increased to about 6 mg. per day.

The author concludes from these tests that neither the lactone nor the dihydroxy acid moiety are normal intermediates in the metabolism of pantothenic acid in man.

**Absorption and excretion of calcium pantothenate by normal and depleted dogs.** R. H. SILBER (*Arch. Biochem.*, 7 (1945), No. 2, pp. 329-336).—The urinary excretion of test doses of calcium pantothenate was significantly greater in normal dogs than in depleted animals whether the doses were given orally or subcutaneously. Intestinal absorption was found to be normal in both groups when tested with oral doses of riboflavin.

Urinary excretion of oral doses of calcium pantothenate ranged from 1 to 50 percent, varying inversely with the amount of food consumed with the vitamin dose. If food were supplied ad libitum, large portions of the dose passed through the intestinal tract unabsorbed. No increase in fecal excretion was noted when the dose was given parenterally.

Tests made on a group of laboratory workers showed that during a 4-hr. period after ingestion of a 50-mg. dose of calcium pantothenate, 10 percent was excreted in the urine.

**The fate of tryptophane in pyridoxine-deficient and normal dogs.** H. E. AXELROD, A. F. MORGAN, and S. LEPKOVSKY. (Univ. Calif.). (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 155-164).—Young cocker spaniels, fed purified diets containing 45.8 or 18 percent casein and ample supplements of all vitamins except pyridoxine, excreted kynurenine and xanthurenic acid but no kynurenic acid when fed single doses of 2 gm. of *dl*-tryptophan or 1.5 gm. of *l*(-)-tryptophan. Similarly treated animals, on the same diet supplemented with pyridoxine, excreted kynurenine and kynurenic acid but no xanthurenic acid, except traces after administration of the *dl*-tryptophan. These products did not appear in the urines except after the tryptophan supplement was given.

The dogs excreted xanthurenic acid following the administration of tryptophan after subsisting only 30 days on the pyridoxine-deficient regime. This abnormality continued throughout prolonged periods up to 407 days.

Symptoms in the more severely deficient dogs included nausea, anorexia, and sometimes collapse after ingesting the tryptophan, but the normal animals and those in the earlier stages of the pyridoxine deficiency were unaffected.

The moderate-protein, pyridoxine-deficient diet produced the same symptoms as did the high protein diet, but somewhat less rapidly. The high protein diet supplemented with pyridoxine, adequate pantothenic acid, and all other vitamins except nicotinic acid, and any unknowns except those present in the cornstarch used, allowed young dogs to develop normally, to maintain normal hemoglobin levels, and to metabolize tryptophan normally.

Removal of the spleen had no effect on the course of tryptophan metabolism in the pyridoxine-deficient animals.

Xanthurenic acid fed to one normal and one deficient dog was excreted unchanged in both cases.

On the specificity of dye titration for ascorbic acid, J. TUBA, G. HUNTER, and H. R. STEELE (*Canad. Jour. Res.*, 24 (1946), No. 1, Sect. B, pp. 37-45, illus. 3).—Vitamin C was determined by the dye titration method using 2,6-dichlorophenolindophenol in a number of fresh, boiled, and otherwise treated plant materials. Comparative values are given for ascorbic acid assayed by the above method; nonvitamin reductants as determined by the Mapson and the Levy methods; and dehydroascorbic acid as determined by reduction with zinc, with hydrogen sulfide, and by the colorimetric method of Roe.

In the fresh, uncooked materials examined, nonvitamin C reductants were negligible. In the cabbage, peas, and pigweed leaves dehydroascorbic acid exceeded 10 percent of the ascorbic acid value. Rose hips contained no significant amounts of either dehydroascorbic acid or of nonvitamin C reductants even after long storage at room temperatures. In rose hips the dye titration method gave an accurate measure of ascorbic acid.

It is concluded that the dye titration method determination of vitamin C is highly specific, but in the case of certain cooked foodstuffs nonvitamin C dye reductants may, without check by other methods, introduce significant errors.

Ascorbic acid content of freshly harvested vegetables, F. O. VAN DUYN, S. M. BRUCKART, J. T. CHASE, and J. I. SIMPSON. (Univ. Ill.). (*Jour. Amer. Dietet. Assoc.*, 21 (1945), No. 3, pp. 153-154).—Vegetables grown experimentally under the supervision of the department of horticulture at the University of Illinois were harvested at the optimum stage of maturity for table use. Ascorbic acid assays were made by the indophenol dye titration method on the day the vegetables were harvested. Several varieties of most of the 14 vegetables tested were studied, assays being made over a 3-yr. period. The tabulation presented gives information by vegetables on variety; date harvested; moisture content; number of determinations; and ascorbic acid content on a fresh weight basis, listing range, mean, and average deviation. The range of ascorbic acid values in milligrams per gram for each of the 14 vegetables was: Broccoli, 0.91-1.72; cabbage, 0.40-0.49; carrots, 0.039-0.160; celtuce (leaves), 0.41-0.55; corn 0.09-0.21; eggplant, 0.027-0.083; mustard greens, 1.07-1.42; peas, 0.19-0.41; rhubarb, 0.056-0.088; snap beans, 0.12-0.28; soybeans, 0.18-0.37; spinach, 0.43-0.77; squash, 0.14-0.18; and Swiss chard (leaves only), 0.25-0.46.

Ascorbic acid content of cabbage salads, V. P. QUINN, F. I. SCOULAR and M. L. JOHNSON (*Food Res.*, 11 (1946), No. 2, pp. 163-168).—Ascorbic acid determinations were made by the indophenol dye titration method of Burrell

et al. (E. S. R., 84, p. 422) after blending the samples in a Waring blender. The Flat Dutch variety of cabbage was used throughout the study.

Samples were carefully prepared and shredded with a stainless-steel knife or a shredder. Assays were made immediately after shredding and after standing 20 min. Losses of ascorbic acid ranged from 34.5 to 42.1 percent after 20 minutes' standing, and were slightly higher in those samples prepared with the shredder.

Other experiments were carried out whereby immediately after shredding one of the following dressings was mixed with the cabbage: French dressing, vinegar mayonnaise, and lemon-juice mayonnaise. Samples were then stored for 30 min. and 5 hr. at room temperature and in the refrigerator.

Results are tabulated and analyzed statistically. The cabbage showed an initial value of approximate 30 mg./100 gm. When mixed with the salad dressing, retention values were found to average 79 percent after standing 30 min. at room temperature and 74 percent after 5 hours' exposure; in the refrigerator, average ascorbic acid values were 86 per cent after 30 minutes' exposure and 81 percent after a 5-hr. period. The lemon-juice mayonnaise offered more protection at both room and refrigerator temperatures than either the French dressing or the vinegar mayonnaise. Both the vinegar and lemon-juice mayonnaise gave higher ascorbic acid retentions than the French dressing.

**Ascorbic acid content of tomato varieties and its retention in processed products.** C. C. STRACHAN and F. E. ATKINSON (*Sci. Agr.*, 26 (1946), No. 2, pp. 83-94, illus. 1).—Analyses for ascorbic acid of 31 varieties and strains of tomatoes were made using the sodium 2,6-dichlorophenolindophenol dye method of Bessey and King. Results showed marked variation with variety, season, and picking of the tomatoes. The Signet variety was consistently high, having a mean value of 29.8 mg. per 100 gm. over the 3-yr. period studied; Clark Early and Sugawara also showed consistently good values, with 23.8 and 23.0 mg. per 100 gm., respectively.

A survey was made of commercially canned juice and tomatoes in British Columbia and eastern Canada, and their ascorbic acid values were determined. In 1941, British Columbia products showed mean values of 22.3, and 1944 values of 19.8; eastern Canada products showed values of 14.4 in 1942 and 15.0 in 1944.

Factory conditions affecting the retention of ascorbic acid were studied, and analyses of steps in processing revealed that under proper conditions, the total loss from the raw fruit to the finished product should not exceed 11.7-13.5 percent. The effect of methods of extraction and sterilizing time and temperatures on the retention was insignificant, except in those cases of excessive sterilization.

**Field illumination and commercial handling as factors in determining the ascorbic acid content of tomatoes received at the cannery.** G. F. SOMERS, K. C. HAMNER, and W. L. NELSON. (U. S. D. A. et al.). (*Jour. Nutr.*, 30 (1945), No. 6, pp. 425-433).—Preliminary studies showed wide differences in ascorbic acid content of commercially canned tomato juice bought in the open market—4.6 to 16.1 mg./100 cc. Widest variations occurred with different brands; only minor variations were noted, in general, with different samples of the same brand.

Carefully controlled experiments were made to determine ascorbic acid losses from the time of picking the tomatoes in the field to the arrival at the trimming line in the cannery. Little loss was noted here. On the other hand, considerable variation in the ascorbic acid content was found from one

field of tomatoes to the other. Studies made on the amount of light in each field for 18 days prior to harvest indicated that close correlation existed between light and the ascorbic acid content of tomatoes.

The authors suggest that variations in the initial amount of ascorbic acid content of the fresh tomatoes may be an important factor in the final content of market tomato juice.

## TEXTILES AND CLOTHING

Operating instructions and test procedure for A. A. T. C. C. flammability tester (*Amer. Dyestuff Rptr.*, 35 (1946), No. 9, pp. 230-232, illus. 2).—This is a tentative test method for evaluating textile materials for flammability characteristics by measurement of the rate of burning. The sample is combed, dried, dessicated, and tested on the apparatus described. The results on five sample tests are averaged, and if the fabric burned in 6 sec. or higher, it is not considered dangerously flammable. As suggested in the interpretation of the test results, no individual sample should show a flammability rate less than 5 sec.

The resistance of treated cotton fabrics to attack by termites and micro-organisms, R. A. ST. GEORGE and M. S. FURRY. (U. S. D. A.). (*Amer. Dyestuff Rptr.*, 35 (1946), No. 8, pp. 207-210, illus. 1).—"The effectiveness against attack, both by termites and by micro-organisms, of 16 finishing treatments applied to cotton fabric has been determined. In general, finishing treatments that protect fabric from attack by termites also made it resistant to micro-organisms. However some effective mildew-resistant treatments allowed slight attack by termites, and two allowed heavy attack.

"The following treatments gave excellent protection against attack by both agencies: Cuprammonium hydroxide, copper oleate, a mixture of copper naphthenate and copper oleate, mercuric chloride with 8-hydroxyquinoline, and copper naphthenate. The following treatments permitted light attack by termites and, with the exception of cuprammonium fluoride, gave excellent protection against micro-organisms: Cuprammonium fluoride, copper sulfate with 8-hydroxyquinoline, and two different proportions of each of two natural dye extracts, Osage orange and quercitron, with copper sulfate and potassium dichromate. The remaining five treatments, under the conditions of this test and in the concentrations used, were ineffective in preventing termite damage."

The effect of weathering on cotton fabric containing certain copper rot-proofers, C. H. BAYLEY and M. W. WEATHERBURN (*Canad. Jour. Res.*, 24 (1946), No. 3, Sect. F, pp. 193-202).—"On exposure to outdoor weathering for 3 mo., No. 8 cotton duck showed substantial loss in breaking strength. The untreated fabric showed a loss of the same order as the losses of samples treated with copper naphthenate, copper hydroxynaphthenate, copper oleate, and copper tallate containing 0.1 to 1.0 percent copper. The copper treated samples showed slight evidence of increased actinic degradation as measured by cuprammonium fluidity. There was an appreciable decrease in the copper content of the treated samples on weathering. The decrease in copper content and breaking strength on weathering and the extent of attack by micro-organisms in soil burial testing were reduced considerably by the presence of a waterproofing compound of the wax-pigment-filler type. The initial water resistance of the proofing was modified by the presence of the copper compounds, being reduced by copper naphthenate, oleate, and tallate and increased by copper hydroxynaphthenate, although on aging and weathering these effects were minimized."

**Evaluation of fastness to atmospheric fumes of dyed cellulose acetate rayon** (*Amer. Dyestuff Rptr.*, 35 (1946), No. 7, pp. 174-176, *illus.* 5).—Testing procedures for determining the fading resistance of dyed cellulose acetate rayon to fumes whiles in general storage, after dry cleaning, and washing are covered. Three forms of suitable apparatus for exposing the samples to the air and to gas are illustrated.

**A low cost reflectometer and method for comparing detergency**, M. L. HURWITZ (*Amer. Dyestuff Rptr.*, 35 (1946), No. 3, pp. 83-84, *illus.* 2).—The procedure described consists of soiling, laundering, and comparing samples of material treated under standard conditions of temperature, time and action. The cleansing action of the various detergents used in the washing test is measured by the brightness of the samples, which is obtained from direct readings on the microammeter of the 45° reflectance" reflectometer described. The test method and equipment discussed yield reproducible results, and numerical indices can be assigned to the value of the various detergents.

## REPORTS AND PROCEEDINGS

**Report of the Federal Experiment Station in Puerto Rico, 1945.** (Partly coop. U. S. D. A. et al.). (*Puerto Rico Fed. Sta. Rpt. 1945*, pp. 62+).—This report notes progress on the propagation, physiology, and culture of derris and the effect of storage on undried derris root; the relative toxicity of seed of the mamey tree (*Mammea americana*) and pyrethrum; toxicological value of other native plants; *Cinchona* propagation, culture, and genetics, and its susceptibility to insect pests; variety tests with onions, lettuce, cabbage, tomatoes, and other vegetables, and tests of vegetables at higher altitudes; direct seeding of mangosteen (*Garcinia mangostana*); plant introduction and distribution; fertilizer and seed production tests with Manila grass (*Zoysia matrella*); physiological studies of the tapping of the Para rubber-tree; protection of seed corn ears from storage insects; damage of sugarcane by the sugarcane root caterpillar; insect parasites and predators; DDT for control of the West Indian fruitfly (*Anastrepha mombinpraepitans*) and cockroaches; bamboo culture and utilization and control of powder-post beetle infestations; vanilla culture and processing; culture of lemon grass (*Cymbopogon citratus*); citronella grass varieties; culture of bay trees and Chinese ginger; processing of essential oils; variety tests with coffee; tropical kudzu (*Pueraria phaseoloides*) as a cover crop; and pasture tests with molasses grass and trailing indigo.

**Fifty-third Annual Report of [Wyoming Station, 1943], J. A. HILL** (*Wyoming Sta. Rpt. 1943*, pp. 50).—This report contains notes from the station and substations in agricultural economics on the income on Star Valley dairy farms and current and past beef prices; soil management, including pasture improvement studies, leaching and treatment with gypsum and alum to remove soil alkali, and use of irrigation water and rock phosphate; forage crops, including studies of grazing practices, forms of selenium poisoning, nitrate poisoning from feeds, and feeding value of range grasses; feeding habits of grasshoppers; plant diseases, including disinfection for ring rot in potatoes, relation of excess moisture to potato scab, seed treatment of cereals for blight and smut, and varieties of beans resistant to fungi; cattle and sheep, including vitamin A requirements of breeding ewes, sheep breeding, cattle feeding on native hays, alfalfa, bonemeal, and beet pulp, calf feeding on concentrated skim milk, corn gluten feed and cottonseed meal for turkeys, and balanced rations for pullets; animal diseases, including studies on leukemia control, causes of calf diphtheria, and sheep abortion;

wool prices and use of canvas coats on sheep to increase wool production; bees, including resistance to American foulbrood and control measures, development of *Bacillus* larvae, and studies of nosema disease and paralysis of adult bees; foods and nutrition, including the blanching of vegetables before freezing, vitamin preservation in canned beans, cooking quality in potatoes, honey as a sugar substitute, preservation of compressed yeast, and effect of altitude on cooking time; pasture mixtures; cultural studies with wheat, oats, barley, corn, beans, potatoes, sugar beets, and crested wheatgrass; variety tests of potatoes, corn, wheat, oats, barley, alfalfa, and soybeans; control of quackgrass; rotations; trees adapted to the region; early-hatched v. late-hatched chicks; relation of sunshine to egg production; steers on pasture v. dry-lot feeding; rations for lambs and pigs; and meteorological observations.

## MISCELLANEOUS

**Minnesota Farm and Home Science** [May 20, 1946] (*Minn. Farm and Home Sci. [Minnesota Sta.]*, 3 (1946), No. 3, pp. 16, illus. 18).—In addition to several articles noted elsewhere in this issue, this number contains Forrester Rhinehart Immer, 1899–1946, by C. H. Bailey (p. 10) (E. S. R., 94, p. 558); Silage Gives Good Results as Lamb-Feeding Roughage (p. 14); Lead Paint Will Kill Cattle (p. 14); What Capital is Needed to Farm in the Midwest, an epitome of Bulletin 389 (E. S. R., 95, p. 117); and Let's Farm Safely, by C. H. Bailey (p. 16).

**Research and Farming** [January 1946] (*Res. and Farming [North Carolina Sta.]*, 4 (1946), Prog. Rpt. 2, pp. 12, illus. 12).—In addition to several articles noted elsewhere in this issue, this number contains Looking Ahead With the Farmer, by G. W. Forster (pp. 1–2), an economic discussion of the farm outlook; and [Deaths in Turkey Hens], by R. S. Dearstyne, C. H. Bostian, and W. B. Nesbit (p. 3), an analysis of causes of death in the station flock.

**Agriculture in the Americas** [June-July 1946] (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 6-7, pp. 95–110+, illus. 13).—In addition to an article abstracted elsewhere in this issue and miscellaneous notes, this number contains Pan American Day Observance Stresses Agricultural Cooperation, by C. J. Ortega (pp. 95–97, 107, 110); West Indian Conference Studies Caribbean Agriculture, by E. Englund (pp. 101–103, 106); and The Iowa State College Tropical Research Center (E. S. R., 94, p. 557), by C. E. Friley (pp. 104–105) (Iowa State Col.).

[Notes on South American agriculture] (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 4, pp. 63–73, 75, 76, illus. 15).—In addition to an article noted on page 505, this number contains Colombian Cattle Transportation, by J. A. Hopkins (pp. 63–66, 75, 76); Farming From Sea to Clouds, by O. Moore (pp. 67–70), an account of Peruvian agriculture; and Mexico's Istle Industry, by B. du Frane (pp. 71–73).

**L'activité de l'Institut International d'Agriculture pendant la guerre (1940-1945)** (*Rome: Inst. Internatl. Agr.*, 1945, pp. 110).—The progress of the Institute and its various parts during World War II is reported.

**Biological action of radiations**, J. WEISS (*Nature [London]*, 157 (1946), No. 3992, p. 584).—A preliminary account on the biological action of irradiation—e. g., with X-rays,  $\alpha$ -particles, neutrons, etc.

## NOTES

---

**Connecticut [New Haven] Station.**—David C. Walden, analytical chemist and a member of the staff for 19 years, died September 13 at the age of 41 years. A son of the late B. H. Walden (E. S. R., 94, p. 414), he was a graduate of Wesleyan University in 1927. In addition to routine analytical work he had given special attention to causes of livestock poisoning.

**Florida Station.**—*Veterinary Medicine* notes that Dr. Glenn B. Van Ness, instructor and assistant veterinarian at the Arkansas University and Station, has been appointed associate poultry pathologist.

**Idaho University and Station.**—Dr. D. R. Theophilus, head of the department of dairy husbandry, has been appointed dean of the college of agriculture, director of the station, and director of the extension division, effective November 1.

**Illinois University and Station.**—Dr. L. E. St. Clair, assistant professor of veterinary anatomy in the Iowa College, has been appointed head of the department of veterinary anatomy in the College of Veterinary Medicine and chief of veterinary anatomy in the station.

**Iowa College and Station.**—Dr. H. L. Wilcke, head of the poultry husbandry activities, has resigned to engage in commercial work. Dr. A. G. Norman, professor of soils, has accepted a position with the War Department with headquarters at Camp Detrick, Frederick, Md.

**Louisiana University.**—Lindsay S. Olive has been appointed associate professor of botany.

**Michigan College and Station.**—Dr. T. A. Merrill, research associate and extension horticulturist, has been appointed head of the department of horticulture in the Washington College and chairman of the division of horticulture in the Washington Station.

**Cornell University and Station.**—An appropriation of \$50,000 was made by the last legislature for research, teaching, and experimental work with ducks and turkeys. Although concentrated heavily in a single county (Suffolk) on Long Island, which raises 95 percent of the ducks in the State and 45 percent of all in the United States, the duck industry has produced an annual income to farmers of about \$10,000,000, and turkey values of about \$3,000,000. Investigations on disease control will be carried on by the New York State Veterinary College, those with turkeys at Ithaca and those with ducks at a branch station at Farmingdale. Studies on production will be handled by the department of poultry husbandry of the College of Agriculture at Ithaca.

Dr. E. F. Phillips, professor of apiculture since 1924 and for 19 years previously in charge of the apicultural investigations of the U. S. Department of Agriculture, has retired.

**New York State Station.**—Dr. John I. Shafer, assistant professor of vegetable crops, has resigned to go into commercial work and has been succeeded by Curtis H. Dearborn. Dr. John C. Cain, assistant horticulturist on military leave from the Florida Station, has been appointed associate professor of pomology, effective November 1.

**North Carolina College and Station.**—The first state-wide 4-H Club meeting since the opening of World War II broke all attendance records with an enrollment of about 1,300 boys and girls.

Recent appointments include Dr. John M. Jenkins, Jr., associate horticulturist of the South Carolina Truck Station, who will be in charge of vegetable research at the Soils Research Laboratory; Ruby Scholz, specialist in food conservation and marketing; Rose E. Bryan and Lorna Langley, assistants in home management; and Dr. Joseph A. Weybrew, animal nutritionist in the station. J. G. Lassiter, extension horticulturist, has resigned to engage in commercial work.

**Ohio State University and Station.**—A department of dairy husbandry has been established in the College of Agriculture to be headed by Dr. W. E. Krauss, chief of the division of dairy industry in the station. The first full-fledged dairy day to be held at the station since the close of the war drew an estimated attendance of about 4,000.

John G. Dean, Jr., agent in cooperative alfalfa investigations for the U. S. Department of Agriculture, has also been appointed assistant in agronomy in the station with headquarters at Columbus.

**Texas Station.**—*Science* notes that Dr. B. S. Pickett, horticulturist at the Weslaco Substation, has resigned to become professor of horticulture in the University of Georgia. B. S. Schweigert has been appointed nutritionist.

**Utah College and Station.**—Dr. Joseph E. Greaves, head of the department of bacteriology and biochemistry since 1927 and associated with the institution since 1907, retired on June 30 as professor emeritus but with some part-time teaching.

**U. S. D. A. Agricultural Research Administration.**—Dr. W. V. Lambert has been appointed administrator as of November 1 vice P. V. Cardon, who has become special assistant in the Bureau of Plant Industry, Soils, and Agricultural Engineering.

**War Damage in the Far East.**—A report to the U. S. D. A. Office of Foreign Agricultural Relations announces that following the Japanese occupation classes at the Philippine College of Agriculture were continued, together with most essential activities except publications. A recuperative camp for released Filipino war prisoners was established on the campus in 1942 and an internment camp for Allied nationals in 1943, but the college plant was virtually intact to the very last day of Japanese occupation. However, on February 26 and 27, 1945, nearly all buildings were burned, including libraries, records, collections, and equipment, with the loss of life of some personnel. Survivors of the prewar staff, numbering 45, furnished the nucleus available for reopening in July, 1945, with about 300 students. Most of their efforts have been necessarily directed to salvaging and reconstruction. Much progress has been made, including a considerable replenishing of the library by donations from the U. S. Department of Agriculture, State experiment stations, American scientific societies, publishers, and private individuals. An immediate minimum appropriation of 534,500 pesos (\$267,250), exclusive of salaries, is needed for reestablishment, with a long-range program of 1,448,500 pesos. Thus far no appropriations have been made.

Ford M. Milan has recently been appointed by the U. S. War Department to be director of all experiment stations in the American zone in Korea. He reports that libraries of all the agricultural institutions there are in very poor condition.

## RECENT WORK IN AGRICULTURAL SCIENCE<sup>1</sup>

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

**Effects of papain, yeast water, cysteine, and glutathione on gluten dispersion or on disintegration as indicated by gluten recovery and by mixogram patterns,** C. O. SWANSON and A. C. ANDREWS. (Kans. Expt. Sta.). (*Cereal Chem.*, 22 (1945), No. 2, pp. 134-149, illus. 4).—The authors found obvious similarities in the mixogram patterns produced by the presence of yeast water, cysteine, and glutathione. The modifications in the patterns were much greater when the dough was mixed after rest periods than with continuous mixing. Both glutathione and cysteine contain sulphydryl groups, and the boiled yeast water gave a strong nitroprusside test. It appeared that the modifications in patterns caused by these three reactive substances are influenced by such groups. None of the quantities of the three substances used in the present investigation caused decreases in recoverable wet gluten comparable with papain.

The mixogram patterns produced with papain were similar to those with the other three substances from continuous mixing, but with rest periods papain produced distinct pattern differences. Papain showed the most pronounced differences in the quantities of recoverable wet gluten. By increasing the quantities of papain or by lengthening the rest periods the quantities of recoverable gluten were greatly decreased, and no gluten could be recovered when the rest periods were sufficiently prolonged indicating enzymatic disintegration. No such effect with the use of yeast water, cysteine, or glutathione was indicated. Any activation by these three substances of latent proteases present in the flour which might cause enzymatic degradation was not made evident by significant decreases in the quantities of recoverable wet gluten.

**Preparation of the egg yolk lipoprotein, lipovitellin,** G. ALDERTON and H. L. FEVOLD. (U. S. D. A.). (*Arch. Biochem.*, 8 (1945), No. 3, pp. 415-419).—A convenient method for the preparation of the lipoprotein from egg yolk consisted in collecting the crude lipoprotein by passing diluted egg yolk through a Sharples centrifuge and extracting the precipitate with cold ether.

<sup>1</sup> The publications abstracted in these columns are seldom available for distribution by the Office of Experiment Stations. In general, application should be made to the Office of Information of the U. S. Department of Agriculture, Washington 25, D. C., for publications of the Department; to the directors of the State agricultural experiment stations, as listed on page 3 of the cover of this issue, for publications of the several experiment stations; and to publishers of books and journals for material issued by them. Microfilms and photostatic copies, the latter legible without magnifying equipment, may be purchased from the Library, U. S. Department of Agriculture, Washington 25, D. C. Rates and other details will be supplied by the Library on request.

The product thus obtained contained, in addition to lipovitellin, phosphorus-containing substances which were removed by solution in 10-percent NaCl and precipitation by dialysis. The analytical data for the final product agreed well with published values. Approximately 18 percent of egg yolk solids was found to be lipovitellin; roughly 17 percent was isolated by the reported method. The lipoprotein contained approximately 16 to 18 percent of a phosphatide, which appeared to be largely lecithin.

**The sulfur content of the pepsin digestible fraction of protein concentrates.** R. J. EVANS. (Wash. Expt. Sta.). (*Arch. Biochem.*, 7 (1945), No. 1, pp. 33-40, illus. 1).—The author digested 2-gm. samples of the ether-extracted protein with pepsin, as in the estimation of the indigestible fraction of the protein, and determined the sulfur as sulfate after complete oxidation of the protein fraction not dissolved by the pepsin by means of nitric and perchloric acids in accordance with the procedure of Evans and St. John (E. S. R. 95, p. 20). The "digestible" organic sulfur of a protein concentrate is defined as the organic sulfur minus the sulfur not dissolved by pepsin. A coefficient of correlation of +0.925 between the digestible organic sulfur of the protein and the gross protein value of animal protein concentrates was obtained. A coefficient of correlation of +0.877 between the digestible organic sulfur and the chemical protein quality index was computed. From the results observed, it appeared that the pepsin-digestible organic sulfur might have been the limiting factor for the animal protein concentrates and peas studied, but was not the limiting factor for the soybean oil meals or cottonseed meals with the type of diet fed.

**The free tryptophane content of human urine.** B. S. SCHWEIGERT, H. E. SAUBERLICH, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Science*, 102 (1945), No. 2646, pp. 275-277).—The microbiological method with *Lactobacillus arabinosus* as the test organism was used to estimate *l*-tryptophan. Nine normal men consuming average diets served as subjects. Details of the method are presented briefly. Recovery of added tryptophan was found satisfactory at different levels of the test samples.

Results showed excretion of 12 to 30 mg. per day as contrasted to values about 10 times greater obtained by Albanese and Frankston (E. S. R., 95, p. 20). Reasons for the differences obtained by the two methods are discussed.

**Some observations on the acid inversion of sucrose.** T. R. FREEMAN. (Fla. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 2, pp. 101-113).—The author finds that the commercial "inversion" of sucrose by heating its water solution in the presence of acid seldom produces a sirup identical in composition with that which theoretically should be obtained. Invert sirups prepared by boiling and by heating at 190° F. contained more dextrose than levulose, but sirups prepared by heating at 175° contained more levulose than dextrose. The optimum acidity for inverting sucrose at boiling temperature was that of the pH range from 2.0 to 2.6. At the lower heating temperature (175° and 190°), pH values of approximately 1.65 to 1.75 were necessary to obtain satisfactory inversion. Preliminary studies indicated that any of the following acids could be used for making invert sirup: Tartaric, citric, lactic, hydrochloric, sulfuric, and phosphoric. There was a slight improvement in the inversion process as the water content of the uninverted sirup was increased from 27.5 percent to 35.1 percent. Although some discrepancy in the results secured with different boiling periods was noted, 30 min. seemed to be the best average. Invert sirup of good quality was prepared at 175° and 190° by holding the sirup at these temperatures for 45 to 90 min. The exact tem-

perature and time were found to be factors less critical than pH. Sirup prepared with phosphoric acid was found to be as good, on a "Theoretical Sweetness Index" basis, as sirup prepared with tartaric acid, the Theoretical Sweetness Index being defined as the sum of the percentages of the total reducing sugars and of the levulose in the invert sirup. The highest values of this index as here tabulated were obtained by heating at 175° for 120 min. with tartaric acid (index value, 108.91) and for 90 min. with phosphoric acid (index value, 108.58).

**Sunflower and safflower seeds and oils**, R. T. MILNER, J. E. HUBBARD, and M. B. WIELE. (U. S. D. A.). (*Oil & Soap*, 22 (1945), No. 11, pp. 304-307).—Chemical analyses of sunflower and safflower seeds, the hulled seed, and the hulls and oils were made. The 28 samples of sunflower seed, representing 4 varieties grown at 7 locations, contained an average of 29 percent oil which was composed chiefly (51 to 68 percent) of linoleic acid glycerides. The 8 varieties of safflower seeds grown at Huntley, Mont., contained an average of 33 percent oil, with an average content of 78 percent linoleic glycerides. Percentages of ash, nitrogen, sugar, and for the whole seeds and their fractions are presented.

**The preparation of stearic acid from castor oil**, H. A. SCHUETTE and D. A. ROTH. (Univ. Wis.). (*Oil & Soap*, 22 (1945), No. 11, pp. 294-295).—By dehydroxylating the 12-hydroxystearic acid, which was prepared in a pure state by the alcoholysis of fully hydrogenated castor oil, there was obtained in at least 40 percent yield an exceptionally pure stearic acid of which the solidification point was 69.33° C. The procedure described avoids recourse to the necessity of preparing lead soaps for the removal of unsaturated fatty acids and the drudgery of repeated crystallizations as prescribed by other published methods.

**The elimination of flavor reversion in linseed shortening by heat polymerization and solvent segregation of the oil**, O. S. PRIVETT, R. B. PRINGLE, and W. D. MCFARLANE (*Oil & Soap*, 22 (1945), No. 11, pp. 287-289, illus. 2).—The authors established optimum conditions for the high temperature polymerization and solvent segregation of linseed oil to produce a "non-reverting" edible shortening and an improved drying oil. The best oil was obtained by heating at 270°-275° C. for 12-15 hr. while carbon dioxide was continuously passed through the oil. Under these conditions the polymerized oil had a refractive index of 1.4858 to 1.4861 at 25°, and yielded 60-65 percent of acetone soluble oil with a refractive index of 1.4830 to 1.4834 at 25° and an acid value of less than 1 percent, calculated as oleic acid. Pie crusts containing shortenings made from the acetone-soluble fraction of the oil were judged to be of good quality. The best shortenings were obtained by hydrogenating to a refractive index of 1.4615-1.4605 (60°).

**The effect of various reagents on adrenocorticotrophic hormone**, C. H. LI, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Arch. Biochem.*, 9 (1946), No. 2, pp. 259-264).—The effects of ketene, nitrous acid, formaldehyde, and iodine on the adrenocorticotrophic hormone were such as to suggest that both the free amino and tyrosine groups are essential for the hormonal action.

**Growth requirements of a purine-deficient strain of Neurospora**, J. G. PIERCE and H. S. LORING (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 409-415, illus. 1).—In work based essentially upon the technic devised by Horowitz and Beadle (E. S. R., 92, p. 8), the authors have studied the growth requirements of *Neurospora* strain 3254. This mutant requires adenine or certain closely related compounds for adequate growth. In a basal medium composed of simple

salts, sugar, and biotin, the following supplements produced adequate growth of the organism: Adenine, oxyadenine, adenosine, and hypoxanthine.

"Adenine in combination as nucleoside, nucleotide, ribonucleic acid, or cozymase is also available for growth, but the relative activity of these compounds is dependent on the amount of adenine present. The rate of growth on extracts of several natural products, including liver, malt, and *Neurospora*, shows that one or more of the active compounds mentioned above is present in such preparations."

**Propionic acid, sodium propionate, and calcium propionate as inhibitors of mold growth.**—II, Studies pertaining to the active agent responsible for the inhibitory effect of the propionates, J. C. OLSON, JR., and H. MACY. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 3, pp. 173-180, illus. 3).—The equation for acid dissociation was applied to data concerning inhibition of the growth of *Hormodendrium cladosporioides*. The concentrations of undissociated propionic acid, propionate ions, and total propionate in the media are given, showing their relationship to the inhibition of the growth of this mold. No correlation between growth and concentration of total propionate or propionate ions was apparent. Increased inhibition of growth could be observed with a corresponding increase or decrease of pH. The undissociated acid was the only component for which a correlation with growth inhibition was obtained. Growth gradually diminished as the concentration of undissociated propionic acid increased. The critical concentration at which growth was completely inhibited was within the range 0.0105-0.0106 M. Within the range of these data, at least, hydrogen ions and propionate ions were of importance only insofar as they affected the concentration of undissociated acid.

**The role of corn steep liquor in the production of penicillin.** J. P. BOWDEN and W. H. PETERSON. (Wis. Expt. Sta.). (*Arch. Biochem.*, 9 (1946), No. 3, pp. 327-339).—No satisfactory substitute for corn steep liquor was found among more than 20 natural materials tested. Some of these, however, particularly meat scraps meal and potatoes, supplemented the action of corn steep liquor in increasing the yield of penicillin. Samples of corn steep liquor from different manufacturers varied greatly in their penicillin-producing capacity, but the variations were as great in lots from the same manufacturer as in lots from different manufacturers. Fermentation of the corn steep liquor with yeast seemed to increase rather than decrease the penicillin-producing potency. The optimum level of corn steep solids in shaken flasks was found to be 2 percent when either *Penicillium notatum* 832 or *P. chrysogenum* X-1612 were used. Data obtained with larger volumes of medium under aeration and agitation indicated that 4 percent corn steep solids was optimal. The most potent steep prepared in the laboratory was obtained from sprouted corn, extracted at 65° C., pH 6, in the presence of 0.24 percent Na<sub>2</sub>SO<sub>4</sub>. The most active part of the steep liquor was extracted from the corn during the first 24 hr.

**Distribution and general properties of an amylase inhibitor in cereals.** E. KNEEN and R. M. SANDSTEDT. (Nebr. Expt. Sta.). (*Arch. Biochem.*, 9 (1946), No. 2, pp. 235-249, illus. 1).—The presence in wheat endosperm of a substance which inhibits salivary and pancreatic amylases was demonstrated. This substance inhibited also the amylase produced by the growth of certain bacterial isolates. A similar water-soluble inhibitor was found present in rye and in Leoti and Schrock sorghums. No evidence of the presence of inhibitor in other cereals could be detected. The inhibiting substance was shown to be resistant to the action of temperatures at or below that of atmospheric

boiling but to be destroyed by autoclaving. It was soluble in water, very dilute salt solutions, and dilute ethyl alcohol, but was insoluble in concentrated ammonium sulfate solutions, in ether, and in 90-percent ethyl alcohol. It did not pass through cellophane dialysis membranes. The reaction of the inhibitor with salivary amylase was reversible. From a mixture of the two, salivary amylase could be precipitated practically free from inhibitor by 70-percent alcohol.

The presence of an inhibitor of both salivary and pancreatic amylase in wheat or wheat flour even when cooked by the usual procedures appeared to have little physiological significance. It was destroyed by the action of pepsin and, with normal proteolysis, would not be effective during digestion by pancreatic enzymes.

**The mode of action of an amylase inhibitor from wheat, W. MILITZER, C. IKEDA, and E. KNEEN.** (Univ. Nebr.). (*Arch. Biochem.*, 9 (1946), No. 3, pp. 321-329, *illus. 1*).—This paper reports upon an extension of the above observation of Kneen and Sandstedt that wheat, rye, and some sorghums contain a proteinaceous substance inhibitive toward salivary, pancreatic, and some bacterial amylases. The present paper discusses the inhibitory effect toward salivary amylase action upon starch from the viewpoint, especially, of reaction kinetics.

The effectiveness of the inhibitor, as obtained from wheat, increased when its solution was held up to 91 hr. The reaction between the salivary amylase, starch, and the inhibitory substance was found to constitute a noncompetitive inhibition. The experimental evidence indicated the tryptophan of the inhibitor protein as the essential amino acid component of the molecule. Reagents known to be specific for tryptophan inactivated the inhibitor. The active inhibitor did not yield a nitroprusside test for the sulfhydryl group. Sodium cyanide reduction produced sulfhydryl groups but did not inactivate the inhibitor. The tyrosine unit was not found to be present. The inhibitor gave strong tryptophan reactions. The inhibitor was inactivated by compounds reacting with amino groups (phenyl isocyanate) or with the indole grouping of the tryptophan residue (aldehydes).

**The preparation and properties of an amylase inhibitor of wheat, W. MILITZER, C. IKEDA, and E. KNEEN.** (Univ. Nebr.). (*Arch. Biochem.*, 9 (1946), No. 3, pp. 309-320, *illus. 1*).—The amylase inhibitor from wheat was purified by adsorption and elution from aluminum hydroxide, a 750-fold concentration from the original wheat being effected. The inhibitor was precipitated from solution by protein precipitants, did not dialyze through a viscose membrane, and was inactivated by nitrous acid and by digestion with ficin. It was concluded that the inhibitor is a protein.

On dialyzing a solution of the purified inhibitor against distilled water inactivation occurred. This did not occur when dialysis was carried out against tap water, sodium chloride, or phosphate buffer. At alkaline pH values the inhibitor was readily denatured at 95° C. in 10 to 15 min. At acid pH values it was much more stable and required more than 60 min. Sodium sulfite, hydrogen sulfide, and ascorbic acid inactivated the inhibitor. Chlorine, bromine, sodium chlorite, and hydrogen peroxide caused a destruction of the inhibitor more readily than did the reducing agents mentioned.

**Sorghum amylase, E. KNEEN.** (Nebr. Expt. Sta.). (*Cereal Chem.*, 22 (1945), No. 2, pp. 112-134, *illus. 6*).—The amylase system of sorghum malt was found to be composed of an  $\alpha$ -amylase accompanied by relatively minute quantities of  $\beta$ -amylase. Both of these amylases appeared to be similar in many properties to the corresponding components of the barley malt system.

When compared with barley  $\alpha$ -amylase, the  $\alpha$ -amylase of sorghum malt had the same optimum pH range for activity (in the neighborhood of pH 4.5), a similar trend in exhibiting a stability optimum at a higher pH value than that optimum for activity, a similar relationship between starch liquefying and starch dextrinizing activities, and a comparable lack of efficiency in the conversion of starch to fermentable sugars. Sorghum  $\alpha$ -amylase was similar to that of barley malt in thermostability, and it too was stabilized in this respect by the presence of calcium ions. It differed in showing a lower production of reducing groups per unit of  $\alpha$ -dextrinizing activity in the initial stages of starch conversion.

The traces of  $\beta$ -amylase in sorghum malt were too minute to be recorded by customary methods of evaluation. The content of this enzyme was determined by comparing the action of a sorghum malt extract with the action of sorghum  $\alpha$ -amylase (heated extract) over an extended period of saccharification. The  $\beta$ -amylase activity was found to be of the same order of the  $\alpha$ -amylase activity of ungerminated cereals—from one hundredth to one thousandth of the activity of a cereal rich in  $\beta$ -amylase. These minute amounts of  $\beta$ -amylase were sufficient to influence greatly the post-dextrinization saccharification of starch by sorghum malt extracts; a level of conversion to fermentable sugars approaching that brought about by barley malt was obtained by prolonged action.

The starch conversion limits from the actions of sorghum malts appeared to be modified by another factor in addition to  $\alpha$ - and  $\beta$ -amylase. This third component, tentatively called "dextrinase," may be influential in the splitting of dextrans to fermentable sugars.

**Lipoxidase**, E. L. COSBY and J. B. SUMNER. (Cornell Univ.). (*Arch. Biochem.*, 8 (1945), No. 2, pp. 259–264, illus. 1).—The authors have devised a method for the purification of soybean lipoxidase by means of which the enzyme is concentrated 60-fold. An adaptation of the qualitative carotene decolorization test for lipoxidase assay is also described. In contrast to the observations reported by Balls, Axelrod, and Kies (*E. S. R.*, 90, p. 436), the present authors found no activating effect to be produced by the purified "activator" described by the preceding investigators. Some crude preparations of the activator had an apparent activating action, but this was shown to be due to the fact that the crude activator was itself capable of lipoxidase activity.

**Studies on the enzyme which produces the *Streptococcus lactis* R-stimulating factor from inactive precursor substance in yeast**, M. LASKOWSKI, V. MIMS, and P. L. DAY. (Univ. Ark.). (*Jour. Biol. Chem.*, 157 (1945), No. 2, pp. 731–739, illus. 4).—The enzyme which produces the *S. lactis* R growth-stimulating factor from inactive precursor substances in yeast has been assayed quantitatively. The distribution of the enzyme has been studied in the organs of the rat, and in a few organs of the dog, hog, cow, rabbit, and chicken.

The partial purification of this enzyme is described. It involves treatment with calcium phosphate gel, precipitation with alcohol, and repeated concentration of the solution and salting-out with sodium sulfate. By this method, a preparation with an average potency of 200 units per mg. of protein, with a yield of 70 percent, was obtained from chicken pancreas. This enzyme exhibits optimal activity between pH 7 and 8, it is rapidly inactivated by exposure to temperatures above 45°, and it is relatively stable to the action of crystalline trypsin.

**Studies on vitamin B<sub>6</sub> conjugase from chicken pancreas**, V. MIMS and M. LASKOWSKI. (Univ. Ark.). (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 493–

503, *illus.* 4).—Continuing the studies described above, the authors present an improved method for the preparation of chicken pancreas conjugase. This method consists of autolysis for 24 hr. at pH 8 at 32° C., followed by fractional precipitation with ammonium sulfate (40 to 80 percent saturation at pH 7), precipitation with alcohol, and a second fractionation with ammonium sulfate.

Chicken pancreas conjugase was activated in the presence of calcium, the optimal concentration being 0.01 M. Optimal pH and temperature were found to be 7.8 and 32°, respectively.

The authors propose a new unit of conjugase defined as 10 times the amount of enzyme which produces 0.1 $\gamma$  of vitamin B<sub>6</sub> when incubated with 1 $\gamma$  of vitamin B<sub>6</sub> conjugate for 1 hr. at 32° in the presence of 0.01 M CaCl<sub>2</sub> in 0.2 M borate buffer, pH 7.8, total volume 1 cc. "Increase of reducing power was observed as a result of incubation of the conjugase with several different substrates and was found to parallel the release of vitamin B<sub>6</sub>, but no decisive evidence was accumulated to show that this was due to a release of a sugar."

**Stereochemical configuration and provitamin A activity.**—IV, Neo- $\alpha$ -carotene B and neo- $\beta$ -carotene B, H. J. DEUEL, JR., C. JOHNSTON, E. R. MESERVE, A. POLGAR, and L. ZECHMEISTER. (*Arch. Biochem.*, 7 (1945), No. 1, pp. 247-255, *illus.* 3).—The preceding papers of this series were abstracted in another section (*E. S. R.*, 93, p. 803).

In the work here noted, neo- $\alpha$ -carotene B and neo- $\beta$ -carotene B were shown to be stable for at least 2 weeks when dissolved in a commercial, edible cottonseed oil and kept under carbon dioxide in the dark at 4° C. The provitamin A activity of neo- $\alpha$ -carotene B was found to be 30 percent of that of all-trans- $\alpha$ -carotene, while neo- $\beta$ -carotene B exhibited a potency which corresponded with 53 percent of that of all-trans- $\beta$ -carotene. Some general conclusions concerning the structure, configuration, and provitamin A activity of carotenes are offered.

**Absorption spectrum of  $\zeta$ -carotene**, H. A. NASH and F. P. ZSCHEILE. (*Ind. Expt. Sta.*). (*Arch. Biochem.*, 7 (1945), No. 2, pp. 305-311, *illus.* 2).— $\zeta$ -Carotene was prepared in solution by extraction of fruits from special tomato strains. After repeated adsorption-column separations upon various adsorbents and a saponification procedure to remove a waxy impurity, specific absorption coefficients were calculated from weight data obtained by evaporating the solutions to dryness in a CO<sub>2</sub> atmosphere. Absorption curves and specific absorption coefficients are presented. This carotene exhibited typical isomerization phenomena, and the shape of its absorption curve was similar to that of lycopene. It is believed that this compound may occur in nature in a wide variety of sources.

**Desthiobiotin in the biosynthesis of biotin**, E. L. TATUM. (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 455-459, *illus.* 1).—An X-ray produced mutant of *Penicillium chrysogenum*, strain 62078, was found to require biotin for growth but was unable to grow in the presence of desthiobiotin. Filtrates made from a culture of strain 62078 (grown on biotin) were tested with the following organisms: *Neurospora crassa* 1A, *Escherichia coli* strain 58, and *Penicillium notatum* strain 21464. These three organisms, which respond to both biotin and desthiobiotin, grew well when the filtrates were substituted for biotin in the medium. Strain 62078 was unable to grow when the filtrate replaced biotin in the usual medium.

From these results, the author suggests that the mutant, strain 62078, has synthesized desthiobiotin, which is a normal intermediate in the biosynthesis of biotin by *P. chrysogenum*.

Addition of pimelic acid to the biotin-containing medium in which strain 62078 is grown increased the production of active substance (desthiobiotin) approximately tenfold. The addition of cystine had no effect.

**Studies on the liberation of compounds in the folic acid group, T. D. LUCKEY, G. M. BRIGGS, JR., P. R. MOORE, C. A. ELVEHJEM, and E. B. HART.** (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 395-403, illus. 1).—Various substances were assayed for folic acid activity using *Streptococcus faecalis* and *Lactobacillus casei* as the test organisms. The substances tested were meats (ham, beef, kidney, liver, and liver powder), skim milk, yeast and yeast extract, beets, wheat, orange juice, various liver fractions, and grass juice powder. The substances were extracted by one or more of the following treatments: Takadiastase digestion at pH 4.5 for 24 hr. at 37° C.; enzymatic extraction with chicken pancreas at pH 8 for 24 hr. at 37°; other enzymes (clarase, papain, pepsin, pancreatin, ficin, and mylase P) at optimum pH for 24 hr. at 37°; hydrolysis at pH 4.0 for 12 hr. at 15 lb. pressure; alkaline hydrolysis in 2 N or 0.1 N base and autoclaved ½ to 1 hr. at 15 lb. pressure; and simple autolysis in water for 24 hr. at 37°.

The results were extremely variable depending upon the material being studied. Takadiastase digestion gave maximum values for most meats. The enzyme prepared from chicken pancreas worked well on certain materials such as Difco yeast extract. Autoclaving at pH 4 for 12 hr. under 15 lb. pressure gave the highest folic acid values for certain liver preparations.

**Studies on the formation of folic acid by incubating *Lactobacillus casei* factor and pyracin with chick liver, L. J. DANIEL, M. L. SCOTT, L. C. NORRIS, and G. F. HEUSER.** (Cornell Univ.). (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 265-271).—This is a continuation of the studies of Scott et al. (*E. S. R.*, 93, p. 759) on the relationship between *L. casei* factor (LCF), pyracin (P), and folic acid (FA).

Incubation of LCF with fresh chick liver caused a marked increase in the FA content as measured by *Streptococcus lactis* R. If both LCF and P are incubated with the liver, the increase in FA content is nearly double that produced when liver is incubated with LCF alone. If  $\alpha$ - or  $\beta$ -pyracin lactones replace P in the mixture in which LCF is incubated with liver, an inhibition in the synthesis of FA is noted.

The authors suggest that the action of pyracin in promoting an increased production of FA may be explained by conjugation with LCF to form FA, or by entering into an enzyme system that brings about the conversion of LCF to FA.

**The use of charcoal treated peptone in microbiological assays, H. ISBELL.** (*Science*, 102 (1945), No. 2661, pp. 671-672).—A modification is described for the simplification of the microbiological methods which use *Lactobacillus arabinosus* for the assay of biotin, pantothenic acid, and nicotinic acid.

Charcoal-treated peptone replaces the charcoal-treated casein hydrolysate. The peptone, dissolved in water, is acidified to pH 3.0 and treated with Darco G60 by being stirred for 1 hr. The solution is filtered by suction, and the acidification, charcoal treatment, and filtration of the solution are repeated. The volume is adjusted, and the solution preserved under toluene.

Tabulated results obtained by the casein and peptone methods show excellent agreement between the two procedures.

**Note on the orcinol reagent, W. E. MILITZER.** (Univ. Nebr.). (*Arch. Biochem.*, 9 (1946), No. 1, pp. 85-90, illus. 3).—After using this reagent successfully for several years in the student laboratory, the author encountered difficulties traced, in part, to impurities in the hydrochloric acid. Directions for

the preparation of the reagent in a form which will yield consistent results are given. It was found that the efficiency of the orcinol reagent for the identification of pentoses, pentosans, uronic acids, and polyuronides is dependent on the purity of reagents, the presence of sufficient ferric iron, and the dilution of the reaction mixture with butyl alcohol for observation. The absorption spectrum of the blue pigment in alcohol is characteristic for carbohydrates producing furfural and can be used for qualitative and quantitative work.

**Determination of water in dry food materials—application of the Fischer volumetric method,** C. M. JOHNSON. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 17 (1945), No. 5, pp. 312–316, illus. 2).—The author considers the volumetric method developed by Fischer to be more rapid and specific for water than the vacuum-oven method usually used. A methanolic suspension or solution of the sample is titrated with a reagent composed of iodine and sulfur dioxide dissolved in pyridine and methyl alcohol.

A description is given of the procedures used in assaying samples of starch, sugars, pectin, dried eggs, and dehydrated vegetables and fruit powders. Vacuum-oven values, included for comparison, were found to run slightly lower than those obtained by electro-metric titration.

Tests were made to determine the effects of temperature, time, and particle size of the sample on the accuracy of the method. Certain organic compounds, notably *l*-ascorbic acid, aldehydic and ketonic compounds, inorganic oxides, and oxidizing-reducing agents, were found to interfere with results obtained by the Fischer method. As the amounts of these interfering substances likely to be present in food products are relatively small and would account for less than 0.1 percent of the apparent moisture, their influence on the accuracy of the results was considered to be minor.

**Determination of moisture in peanut kernels,** C. L. HOFFPAUIR. (U. S. D. A.). (*Oil & Soap*, 22 (1945), No. 11, pp. 283–286, illus. 5).—At a pressure of less than 5 mm., peanut material lost some oily distillate at 130° C. though little change in the oil was detected under moisture determination conditions. Losses in weight of 5- and 50-gm. samples of 19-tooth ground and 50-gm. whole kernel peanuts in fresh condition after 5 hr. at 130° in a forced draft oven showed excellent agreement. This was held to indicate that original moisture should be determined on whole kernels and second moisture on 19-tooth or similarly ground kernels by heating for 5 hr. in a forced draft oven at 130°. Some of the values indicated that heating for 3 hr. at 130° in a forced draft oven might be adequate for the second moisture determination. It is pointed out that the shorter heating of the ground sample would also reduce the possibility of oxidative decomposition of the small samples used for second moisture. These procedures are considered to provide conditions of drying which reduced both the first and second moistures to a basis of equal dehydration of the sample material. Errors due to changes in moisture content of peanut kernels during grinding for original moisture are held to be avoided. The methods described are considered to provide a basis for planning collaborative investigations on the procedures for the determination of moisture in peanut kernels for inspection and control purposes in the trade and processing industries.

**The calculation of total solids by means of the Sharp and Hart equations,** B. L. HERRINGTON. (Cornell Univ.). (*Jour. Dairy. Sci.*, 29 (1946), No. 2, pp. 87–89).—The author analyzes the equations set up by Hart and Sharp (E. S. R., 76, p. 844) for the computation of the total solids of milk from its specific gravity and fat content to show the source of an error of about –0.75 percent

in the calculated value. The data upon which Sharp and Hart based their equations were obtained by means of a form of the Westphal balance, the specific gravity having been computed as the ratio of the weights of equal volumes of milk and water, both weighed at a temperature of 30° C., and these specific gravity data converted into Quevenne lactometer readings without correction for the difference due to the fact that the Quevenne instrument gives specific gravity readings relative to the density of water at 60° F. [15.56° C.]. Values of specific gravity at 30° C./30° C. must be, therefore, multiplied by 0.99663 to convert them to values at 30° C./60° F. It is further noted that when a Quevenne lactometer is used at 30° C. it does not indicate exactly the specific gravity referred to water at 60° F., because there is an appreciable expansion of the lactometer when it is warmed from 60° F. to 30° C. If one can assume that the value 0.0002648 given for the cubical coefficient of expansion of glass is applicable to the ordinary lactometer, than one can convert true values of specific gravity at 30° C./60° F. to apparent specific gravities as measured with a lactometer by multiplying by 1.00038. A form of the Sharp and Hart equation, incorporating the corrections noted, is given.

**The microbiological determination of amino acids in animal proteins.** S. W. HIER, C. E. GRAHAM, R. FREIDES, and D. KLEIN. (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 705-716).—The *Lactobacillus arabinosus* technic of Shankman et al. (E. S. R., 92, p. 4) was used for the assay of glutamic acid, leucine, isoleucine, valine, and threonine. Arginine, phenylalanine, and tyrosine were determined with *L. casei* following the procedures of McMahan and Snell (E. S. R., 91, p. 633). Histidine and lysine were assayed with *Leuconostoc mesenteroides* using the improved medium of Dunn et al. (E. S. R., 95, p. 14). The proteins to be assayed were hydrolyzed by refluxing 2-gm. samples with 80 cc. of 8 N HCl for 8 hr. in all glass equipment. The hydrolysate was then diluted, neutralized, and adjusted to 1 l. and filtered. Casein, beef fibrin, lactalbumin, gelatin, pork pancreas, beef muscle, crystalline bovine albumin, and beef serum were assayed for the ten amino acids mentioned. Evidence is presented of the reproducibility and of the validity of the values reported. Forty-three references are cited.

**Microbiological determination of free leucine, isoleucine, valine, and threonine in dog plasma.** S. W. HIER and O. BERGEM. (Univ. Ill. et al.). (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 717-722).—The *Lactobacillus arabinosus* procedure (described above) was applied to the determination of free leucine, isoleucine, valine, and threonine in plasma. Blood from 12 fasted mongrel dogs was used, and tungstic acid filtrates of the plasma were prepared.

Results showed the following values in micrograms per cubic centimeter of plasma: Leucine, 14.3 to 30.6; isoleucine, 8.7 to 19.5, threonine, 15.0 to 35.0; and valine, 15.2 to 30.3  $\gamma$ /cc. "Five samples of dog plasma were found to contain less than 6.0 $\gamma$  per cubic centimeter of glutamic acid. No differences in the free amino acid content of plasma were found in anesthetized animals as compared with unanesthetized animals."

**Investigations of amino acids, peptides, and proteins.**—XXI, The determination of histidine in protein hydrolysates with *Leuconostoc mesenteroides* P-60, M. S. DUNN, M. N. CAMIEN, S. SHANKMAN, and L. B. ROCKLAND. (Univ. Calif. et al.). (*Jour. Biol. Chem.*, 159 (1945), No. 3, pp. 653-662).—The microbiological method previously described (E. S. R., 95, p. 14), using *L. mesenteroides* P-60 as the test organism, has been used in the assay of histidine. Samples of casein and silk fibroin gave histidine values of 3.1 and 0.34

percent, respectively. Preliminary studies were made on the precipitation of histidine, at pH 7.4, as a silver salt from a casein hydrolysate.

A discussion is included in which the results obtained here are evaluated in relation to values obtained by various other procedures. A list of 26 references is given.

**Investigations of amino acids, peptides, and proteins, XXIII-XXV.** (Univ. Calif.). (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 643-678, illus. 28).

**XXIII.** *The determination of phenylalanine in protein hydrolysates with Leuconostoc mesenteroides P-60 and Lactobacillus casei*, M. S. Dunn, S. Shankman, and M. N. Camien (pp. 643-655).—Microbiological procedures using *Leuconostoc mesenteroides* P-60 and *Lactobacillus casei* as the test organisms have been adapted to the determination of phenylalanine in protein hydrolysates. Results in close agreement for the percentage of phenylalanine in casein and in silk fibroin were found by assays with these organisms. The corrected values of phenylalanine in casein and silk fibroin, respectively, were found to be 4.91 and 1.28 percent under the conditions considered to be most reliable.

It is considered probable that the true value for phenylalanine in casein is  $5.0 \pm 0.2$  percent, as data of high accuracy were obtained in the recovery of phenylalanine from three amino acid test mixtures of different composition and from casein hydrolysates. This figure is in approximate agreement with the values obtained by investigators who employed what appeared to be dependable colorimetric procedures. The authors note, however, that the extent to which phenylalanine is destroyed or altered during the hydrolysis of casein must be measured before the true value for phenylalanine in this protein can be determined with certainty. A bibliography of 51 references is included.

**XXIV.** *The amino acid requirements of Lactobacillus fermenti 36*, M. S. Dunn, M. N. Camien, and S. Shankman (pp. 657-667).—The amino acid requirements of *L. fermenti* 36 were carefully studied. The growth response to glutamic acid, histidine, methionine, and threonine at different levels of total amino acids and the effect of histidine at different levels of NaCl, and KCl, equal mixtures of NaCl and KCl,  $\text{NH}_4\text{Cl}$ , glucose, sodium acetate, purines and pyrimidines, phosphate buffer salts, nonbuffer salts, and vitamins has been measured in terms of acid production. Results demonstrate that histidine and threonine, but not glutamic acid and methionine, are synthesized by *L. fermenti* 36 after 2 days' incubation under the described experimental conditions. The authors conclude that the basal medium and the experimental conditions established on the basis of the described experiments may be satisfactory for the determination of some amino acids with *L. fermenti* 36.

**XXV.** *The determination of histidine in protein hydrolysates with Lactobacillus fermenti 36*, M. S. Dunn, S. Shankman, and M. N. Camien (pp. 669-678).—The basal medium experimentally derived above (paper XXIV) has been specifically modified for the determination of histidine. Preferred assay conditions are described.

The assay of two samples of casein with *L. fermenti* 36 and *Leuconostoc mesenteroides* P-60 under varied experimental conditions indicates that casein contains  $3.0 \pm 0.1$  percent of histidine corrected for moisture and ash. The authors emphasize, however, that the extent to which histidine is destroyed or altered during the hydrolysis of casein must be measured before the true value of histidine in this protein can be determined with certainty. The source and preparation of the casein samples may account for variations in the amino acid content.

Silk fibroin was found to contain 0.33 to 0.35 percent of histidine corrected for moisture and ash by assay with *Lactobacillus fermenti* 36 under varied experimental conditions. Experiments on the recovery of histidine from silk fibroin hydrolysates indicate that these values may be higher than the true figure.

**A bioassay for lysine by use of a mutant of *Neurospora*, A. H. DOERMANN.** (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 95-103, illus. 1).—A method is described for the assay of lysine by the use of a mutant of *Neurospora crassa*. It was found necessary to remove all arginine from the material to be analyzed in order to obtain consistent results, as arginine inhibits the growth of this mutant. Arginine is hydrolyzed to ornithine by the use of a liver arginase preparation.

Over the assay range used, the results were found to be reproducible and good recoveries of added lysine were obtained. Lysine values for four protein hydrolysates obtained by this method were casein, 6.6-6.8 percent; ovalbumin, 6.3; gelatin, 6.9; and gluten, 1.3 percent.

**The Kiliani reaction as a direct measure of reducing groups, W. E. MILITZER.** (*Univ. Nebr.*). (*Arch. Biochem.*, 9 (1946), No. 1, pp. 91-94).—The author showed that the quantity of hydrogen cyanide consumed by a sugar in the Kiliani reaction can be determined by titrating the excess with silver nitrate in the presence of potassium iodide and ammonium hydroxide. Each sugar consumes cyanide in the ratio of 1 mole for each aldehyde, ketone, hemiacetal, or hemiketal group in the molecule. Various classes of sugars could be differentiated from one another on the basis of cyanide consumption. Hexoses were thus distinguished from pentoses and tetroses, and monosaccharides from disaccharides and trisaccharides.

**Note on a biochemical method for determining crude fiber in corn meal, H. W. WOODSON and H. S. MACKENZIE.** (*Univ. Ill.*). (*Cereal Chem.*, 22 (1945), No. 2, pp. 158-160).—The authors note that the determination of crude fiber, "which is the indigestible part of foodstuffs consisting of cellulose, non-water-soluble hemicelluloses, and lignin," is, as ordinarily carried out by boiling successively with 1.25 percent solutions of sulfuric acid and of sodium hydroxide, "probably one of the least accurate of all the analyses" made in the examination of foodstuffs. They developed a simplified enzymatic method which compares favorably with a more expensive and time-consuming enzymatic method. In the analysis of several samples of corn meal, their method gave the average figure 8.23 percent, the more elaborate enzymatic procedure yielding 8.76 percent. This method, as applied to corn meal, gave crude fiber values which were approximately four times as large as those obtained with the customary method. It is also believed that it can be satisfactorily used in the analysis of other cereals.

**Degree of pigmentation and its probable relationship to invertive activity of honey, H. A. SCHUETTE and P. DUBROW.** (*Univ. Wis.*). (*Food Res.*, 10 (1945), No. 4, pp. 330-333).—Invertive activity, measured by the change in the invert sugar content of a honey solution of controlled pH 6 hr. after the addition of sucrose, expressed as milligrams of sucrose hydrolyzed by 1 gm., appeared to bear a qualitative rather than a quantitative relationship to the degree of pigmentation (Pfund scale) of honey. Dark honeys were found to exceed the light ones in this property. By use of the photoelectric colorimeter and an adaptation of the Baier-Neumann test for added sugar in milk, the following average values were found: For the light honeys (water-white, white, and extra light amber) 27; for the dark honeys (light amber, amber, and dark) 132.

**Some factors which affect the determination of oil in soybeans, F. I. COLLINS and O. A. KROBER.** (U. S. D. A. coop. 24 expt. stas.). (*Oil & Soap*, 22 (1945), No. 11, pp. 307-310, illus. 3).—Preparation of the sample by a very fine grinding, such as that obtained by the use of a mill of one of three specified commercial makes, was found essential to an increased oil extraction in the official A. O. C. S. method of analysis. It is believed that much of the increase of 0.2-0.4 percent of oil obtained by regrinding very finely ground soybean meals which has been attributed to reduction in particle size is probably caused by the gain of 3.5 percent in moisture content of the meal due to high humidity at the time of regrinding. The authors' results are held to indicate that by a very fine initial grinding better reproducibility of analyses might be obtained if the regrinding were omitted or the samples exposed for 30 to 50 min. at controlled relative humidity during the regrinding period. Time and technic of exposure of the samples at their regrinding may have caused variations as great as 0.2 percent in oil analyses. The percentage of oil obtained in the last 2 hr. in using the official A. O. C. S. method of oil analysis on finely ground samples was seldom greater than 0.02 percent. Raising to 30° C. the temperature of the cold water which was supplied to the condensers of the oil extraction apparatus prevented condensing of atmospheric moisture without affecting the percentages of oil obtained in the analyses. The heat treatment of soybeans to predry them before their initial fine grinding did not affect appreciably either the Wijs iodine number or the refractive index of the oil which is extracted with petroleum ether.

**Estimation of salt in butter and new cheese by a mercurimetric method, W. S. ARBUCKLE.** (Tex. Expt. Sta.). (*Natl. Butter and Cheese Jour.*, 37 (1946), No. 5, pp. 41-42, 43).—The author proposes to determine the chlorides from butter and cheese samples by titration of their aqueous solutions with a standard mercuric nitrate solution in the presence of *s*-diphenylcarbazone as internal indicator. As applied to butter, the method directs dissolving the residue from the fat and moisture determinations made upon a 10-gm. sample in 250 cc. of water. Of the resulting solution, an aliquot of 25 cc. is to be titrated with 0.1711 N mercuric nitrate made up to contain 40 cc. of 2 N nitric acid in each liter, the added indicator being 0.6 cc. of a solution of 100 mg. of *s*-diphenylcarbazone in 100 cc. of neutral ethyl alcohol. The clear and colorless solution turns a pale violet color on the addition of 1 drop of mercuric nitrate at the end point and an intense violet-blue color on the addition of 1 drop of mercuric nitrate in excess. The cubic centimeters of 0.1711 N mercuric nitrate used in the titration equal the percentage salt in the sample. In solutions containing protein, the color appearing on addition of the indicator was at first "salmon red," changing to violet at the beginning of the titration. With further addition of the mercuric salt, the initially turbid protein solution became clear and either colorless or pale yellow. These changes were followed by the end point change to pale violet. In cheese samples, the chloride content was similarly determined, save that the 10-gm. sample was made up to an aqueous suspension, the suspension heated to 150°-160° F., and cooled to room temperature. Aliquots of the clear solution were titrated as above. The mercuric nitrate solution having been adjusted to 0.1711 N by titration against a standard solution of pure sodium chloride, the volume of the titrant used in cubic centimeters gave the percentage of salt in the sample directly. The method was found accurate, and, as compared with silver nitrate titration with potassium chromate as indicator, to be somewhat more sensitive and to have the advantage of a sharp, permanent end point. On the other hand, "the method does not seem to be adaptable to procedures requir-

ing digestion of the sample, and no satisfactory procedure was found for using the mercurimetric method as a direct titration procedure for determining the chloride content of milk nor for determining the chloride content of chlorine sterilizers used in the dairy industry."

**Detection of raw milk contamination in homogenized milk by means of the phosphatase test and by organoleptic examination,** A. V. MOORE and G. M. TROUT (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 311-316).—Observations with respect to development of rancidity, titratable acidity, pH, and phosphatase tests were made on five series of homogenized and nonhomogenized milk to which various increments of raw milk had been added. During storage at 40° F. raw milk-contaminated homogenized milk increased in titratable acidity, decreased in pH, and developed rancidity. The contamination could be detected positively by the phosphatase test when 0.5 percent raw milk was added, questionably when 0.1 percent was added, but not when 0.05 percent was added. The level of contamination detectable by organoleptic examination depended largely upon the length of the storage period. "In general, at 24 hours' storage, contamination of homogenized milk with raw milk must be at least 4 percent before rancidity can be detected by taste and smell. In no case could organoleptic examination detect the addition of 0.1 percent raw milk when mixtures were held 7 days at 40°. Extracting the phenol with butyl alcohol should be a required step, and not optional in the phosphatase test, particularly when applied to homogenized milk."

**Assay of p-aminobenzoic acid,** D. PENNINGTON (*Science*, 103 (1946), No. 2674, p. 397).—A method very similar to that described by Lewis (E. S. R., 89, p. 412) is described briefly. *Leuconostoc mesenteroides* Pd-60 is the test organism. Assay tubes are incubated at 37° C. for 15 hr. Maximum growth is produced by 0.1 mμg. of p-aminobenzoic acid per millimeter of medium, and growth is measured turbidmetrically. Samples are prepared for assay by autoclaving 1 gm. of sample with 5 cc. of 6 N H<sub>2</sub>SO<sub>4</sub> at 15 lb. pressure for 15 min. The samples are neutralized with Ba(OH)<sub>2</sub>, diluted to an approximate volume, and filtered. Hot water extraction or enzyme hydrolysis liberated only a fraction of the total vitamin present. Alkaline hydrolysis caused heavy destruction of the activity of tissue extracts.

**Modifications in the Acetobacter suboxydans assay for p-aminobenzoic acid,** V. H. CHELDELIN and M. J. BENNETT. (Oreg. State Col.). (*Jour. Biol. Chem.*, 161 (1945), No. 2, p. 751).—The medium developed by Sarett and Cheldelin (E. S. R., 94, p. 429) for the determination of the lactone moiety of pantothenic acid has been found useful in the assay of p-aminobenzoic acid. The β-alanine and p-aminobenzoic acid in the medium are replaced by 200γ calcium pantothenate per liter. Results at various levels were found to be in good agreement.

**Methods of estimating and the effect of variety and protein level on the baking absorption of flour,** K. F. FINNEY. (Kans. Expt. Sta. coop. U. S. D. A. and State expt. stas.). (*Cereal Chem.*, 22 (1945), No. 2, pp. 149-158, illus. 2).—A study of absorption in baking indicated that variations of 2 percent plus or minus the optimum did not significantly alter loaf volumes or grain and texture scores. Absorption determinations could be replicated from one day to the next within limits of about 0.5 percent. In experiments on flours of 10 pure hard winter wheat varieties grown in widely different environments, absorption was observed to be essentially a linear function of protein content within a variety. However, each variety seemed to have a different regression line, the slope of which, in general, increased as the absorption level became greater. The increase in absorption per percent of pro-

tein varied from about 1 percent to slightly more than 2 percent. The level of absorption at 16 percent prolein varied from 63 to over 73 percent, which difference was several times that regarded as being necessary for statistical significance. Regression lines for several varieties were established and successfully used for estimating absorptions in experimental baking since 1939.

**Nutritive value of canned foods, [XI-XII].** (Pa. State Col. et al.). (*Indus. and Engin. Chem., Analyt. Ed.*, 17 (1945), Nos. 8, p. 531; 11, pp. 710-713).—This is a continuation of the series of studies on the nutritive value of canned foods (E. S. R., 94, p. 547).

[XI]. *Comparison of vitamin values obtained by different methods of assay*, N. B. Guerrant, M. G. Vavich, and O. B. Fardig (pp. 710-713).—Six representative foods—carrots, corn, ham, peas, salmon, and tomatoes—were prepared as purees or homogenized to insure uniformity of composition. The products were processed by commercial methods in tin containers. Assays for ascorbic acid, carotene (or vitamin A), thiamine, riboflavin, pantothenic acid, and niacin were carried out by several collaborating laboratories and by one or more of the recommended procedures—biological, chemical, fluorometric, photocolormetric, or microbiological.

Results are tabulated and show considerable variation between laboratories.

The authors conclude that, from the information available, the use of different standards, methods, or equipment cannot be considered the major factor in the discrepancies noted. "It appears that the human element is, perhaps, one of the most significant sources of variable results. . . ." The need for more collaborative assays under vigorously controlled conditions is emphasized.

[XII]. *Determination of ascorbic acid of fresh green peas*, M. G. Vavich, R. M. Stern, and N. B. Guerrant (p. 531).—Reduced ascorbic acid was determined on samples of fresh green peas by the indophenol-titration method. Blending of the sample with 3 percent metaphosphoric acid in ratios of 2 : 1 or 1 : 1, respectively, produced a loss of ascorbic acid which amounted to as much as 97.3 percent in certain cases. The blending of the sample in an atmosphere of nitrogen instead of air materially reduced this loss. By raising the initial concentration of metaphosphoric acid to 6 percent so that the final concentration in the blended mixture was 3 percent of metaphosphoric acid, loss of ascorbic acid was reduced to zero.

**Colorimetric determination of vitamin A**, A. L. FEINSTEIN. (U. S. D. A.). (*Jour. Biol. Chem.*, 159 (1945), No. 2, pp. 569-570).—A preliminary note is presented describing a new colorimetric method for the assay of vitamin A.

Vitamin A oil or ground multivitamin tablets are extracted with chloroform so as to average 600 to 3,000 U. S. P. units per 10 cc. of solution. The chloroform extract is treated with two drops of concentrated HCl followed by 5 cc. of glycerol diochlorohydrin, and then shaken for 5 min. The clear blue-green color which appears in about 30 min. is read in a photoelectric colorimeter (660  $m\mu$  filter).

Vitamin A in the extract is estimated by comparison with a standard vitamin A reference curve determined spectrophotometrically.

Depending upon the lot of dichlorohydrin used, the blue-green color produced is stable for variable lengths of time (3 to 24 hr.). However, if standard reference curves and an unknown sample are run simultaneously, results read after 18 hr. are comparable with those obtained after 30 min.

The use of HCl produces four density peaks when the Beckman spectrophotometer is used and 20  $m\mu$  intervals are read. These peaks occur at approximately 440, 580, 640, and 740  $m\mu$ , while a deep minimum density occurs at 500  $m\mu$ .

**Spectrophotometric study of a new colorimetric reaction of vitamin A.** A. E. SOBEL and H. WERBIN (*Jour. Biol. Chem.*, 159 (1945), No. 3, pp. 681-691, illus. 6).—A new reagent, glycerol, 1,8-dichlorohydrin (GDH), has been used in the colorimetric estimation of vitamin A. Its advantages over other methods are: (1) Stability of color produced, permitting measurements from 2 to 10 min. after the reagents are mixed; and (2) the reagent employed is stable and unaffected by traces of moisture. The one disadvantage is that the extinction coefficient of the color produced is only about one-quarter that of the antimony trichloride blue color.

Spectrophotometric data are presented for the transient blue color produced immediately after the solutions are mixed and for the secondary violet color which is the stable product of the reaction of the reagent with vitamin A. The effect of carotene upon the color formation and its interference with the determination of vitamin A by the reagent was also investigated.

Tabulated results are presented comparing the values obtained by several methods for the various vitamin A concentrates studied.

**Estimation of riboflavin, thiamine, and N<sup>1</sup>-methylnicotinamide—rapid field methods.** R. E. JOHNSON, F. SARGENT, P. F. ROBINSON, and F. C. CONSOLAZIO (*Indus. and Engin. Chem., Analyt. Ed.*, 17 (1945), No. 6, pp. 384-386).—By modifications and simplifications of existing methods, the authors have worked out a rapid field technic for vitamin assay of small volumes of urine.

The riboflavin analysis is based upon the method of Najjar (E. S. R., 87, p. 621). The thiochrome method of Hennessy and Cerecedo (E. S. R., 82, p. 588) as modified by Egaña and Meiklejohn (E. S. R., 87, p. 620) is used to determine thiamine, in conjunction with the Najjar and Wood method (E. S. R., 85, p. 702) for the determination of N<sup>1</sup>-methylnicotinamide. Visual fluorometry and simple rugged apparatus are employed. The authors estimate that by their technic, four technicians can run duplicate analyses of all three vitamins on 100 specimens of urine in two working days.

**Comparative merits of fasting specimens, random specimens, and oral loading tests in field nutritional surveys.** R. E. JOHNSON, C. HENDERSON, P. F. ROBINSON, and F. C. CONSOLAZIO (*Jour. Nutr.*, 30 (1945), No. 2, pp. 89-98, illus. 1).—Tests were made under field conditions on groups of men subsisting on good rations (combat rations). Riboflavin, thiamine, and N<sup>1</sup>-methylnicotinamide assays were carried out by the simplified techniques described above. Analyses of urinary excretion were made on fasting specimens, 4 hr. after a test dose of vitamins, and on random specimens taken throughout the day. Assays included blood hemoglobin, serum protein, serum and urinary chloride, and serum and urinary ascorbic acid. From the results of these tests, the authors conclude that for nutritional surveys "when it is not possible to conduct all the tests that might be desired, fasting levels should be determined in preference to the results of loading tests; that specimens of blood may with reservations be drawn at any time of day; and that random specimens of postprandial urine should be avoided if possible. These conclusions are limited to hemoglobin, serum protein, chloride, and ascorbic acid; and to urinary chloride, ascorbic acid, thiamine, N<sup>1</sup>-methylnicotinamide, and riboflavin."

**The microbiological assay of vitamin B<sub>6</sub> conjugate.** O. D. BIRD, B. BRESSLER, R. A. BROWN, C. J. CAMPBELL, and A. D. EMMETT (*Jour. Biol. Chem.*, 159 (1945), No. 3, pp. 631-636).—A procedure is described for the microbiological assay of vitamin B<sub>6</sub> using *Lactobacillus casei* and a modification of the folic acid method of Mitchell and Snell.<sup>4</sup>

<sup>4</sup>Tex. Univ. Pub. 4137 (1941), pp. 36-37, illus. 1.

In the yeast and liver extracts and concentrates tested, vitamin B<sub>6</sub> was found to exist primarily in the bound or inactive form. Enzymatic liberation of the vitamin was accomplished by treatment with preparations obtained from desiccated hog kidney, extract of fresh and autolyzed hog kidney, and extracts of whole almond or almond meal.

When the natural materials and concentrates were enzyme-treated, the microbiological assay values obtained in most cases were in good agreement with chick antianemia assays. One exception was found with plant extracts (asparagus juice concentrate), in which none of the enzyme preparations used were able to insure a microbiological assay value equal to that obtained with chicks.

**The multiple nature of vitamin B<sub>6</sub>: Critique of methods for the determination of the complex and its components,** D. MELNICK, M. HOCHBERG, H. W. HIMES, and B. L. OSER (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 1-14, illus. 1).—Physical, chemical, microbiological, and biological assay procedures were compared in a critical study of the B<sub>6</sub> activity of biological materials and pure compounds of pyridoxine (1), pyridoxamine (2), and pyridoxal (3).

The ultraviolet absorption curves for pure solutions of the three compounds were made at widely separated pH intervals. Results indicated that (2) and (3) show features of amphoterism similar to that of (1).

An adaptation of the colorimetric procedure (E. S. R., 94, p. 299), by reducing the pH of the reaction and extending the reaction, time allows specific determination of pyridoxine in the presence of the derivatives. Pyridoxine couples with borate and is rendered nonreactive, whereas pyridoxal and pyridoxamine still react with the chloroimide reagent.

Microbiological assays with *Saccharomyces cerevisiae* give low vitamin B<sub>6</sub> values because the biologically active pyridoxine derivatives are appreciably less stimulatory for this organism. These derivatives, however, show comparable activity for *S. carlsbergensis* and for the rat.

The spectrophotometric, chemical, and microbiological data demonstrate that pyridoxine, pyridoxal, and pyridoxamine are all stable to the various hydrolytic procedures used in preparing the samples for assay.

Comparable results by both rat and microbiological assay (with *S. carlsbergensis*) were obtained for all three compounds and for an unidentified labile factor from yeast.

The authors consider the *S. carlsbergensis* method of Atkin et al. (E. S. R., 90, p. 9) to be the most reliable for the assay of all natural materials. For the assay of pharmaceutical preparations, the chemical method is recommended for its rapidity and simplicity. The advantages and difficulties of each method are discussed. Thirty references are cited.

**The determination of oxybiotin in the presence of biotin,** K. HOFMANN and T. WINNICK (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 449-453, illus. 1).—"A procedure has been developed for the determination of oxybiotin in biological materials. The method is based upon the destruction of biotin by dilute potassium permanganate solution and the stability of oxybiotin toward this reagent. The yeast growth-stimulating activity of acid hydrolysates of tissues or micro-organisms following treatment with permanganate appears to be representative of their oxybiotin content.

"This new method has been used to demonstrate that *Saccharomyces cerevisiae* and *Rhizobium trifolii* grown in the presence of oxybiotin utilize this compound as such, and do not convert it into biotin. These results are the first demonstration that the sulfur atom is not essential for the biological activity of biotin."

**The determination of thiamine in urine by means of the thiochrome technique,** O. MICKELSEN, H. CONDIFF, and A. KEYS. (Univ. Minn.). (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 361-370, illus. 1).—A modified thiochrome method is described which has been found to be particularly useful with urine samples which have low thiamine values and high blanks due to interfering substances. The principal features of the method are: (1) The use of small samples of urine (5 cc.) and (2) the treatment of the KCl-HCl solution with NaOH and potassium ferricyanide, followed by a mixture of IICl and H<sub>2</sub>PO<sub>4</sub> to obtain a pH of 8.0 to 9.5 before the addition of the isobutanol.

At this pH, the fluorescence produced by interfering substance is minimum and that produced by thiochrome is optimal. The authors conclude from the results obtained that "the present method never yields negative values, allows satisfactory recovery of added thiamine, and produces theoretical results in mixtures which have been separately analyzed. Previous thiochrome methods fail in these particulars with urines from persons on very low thiamine intakes."

Statistical evaluation of the method gave a standard deviation of 4.6 percent of the mean.

The method yields higher values for urine especially in cases of thiamine deficiency. Diet and food items tested gave essentially the same values with all methods tested.

**A reaction of ascorbic acid with  $\alpha$ -amino acids,** T. KOPPANYI, A. E. VIVINO, and F. P. VEITCH, JR. (*Science*, 101 (1945), No. 2630, pp. 541-542).—A new colorimetric test for the determination of ascorbic acid is described. It has been found to give negative results when tested with other reducing substances, ketones, phenols, or carbohydrates such as sorbitol, glucose, fructose, mannose, xylose, trehalose, arabinose, starches, and *d*-glucurone. When *DL*-alanine and H<sub>2</sub>O<sub>2</sub> are added to ascorbic acid, and the mixture heated and then cooled, a red color appears. The authors consider this color to be developed by dehydroascorbic acid in a manner similar to the ninhydrine or murexide tests. The use of glacial acetic acid increases the sensitivity of the reaction. A discussion is presented of the possible chemical interaction produced.

**The indophenol-xylylene extraction method for ascorbic acid and modifications for interfering substances,** W. B. ROBINSON and E. STOTZ. (N. Y. State Expt. Sta.). (*Jour. Biol. Chem.*, 160 (1945), No. 1, pp. 217-225).—Modifications in Stotz's (*E. S. R.*, 88, p. 153) and Pepkowitz's (*E. S. R.*, 92, p. 10) indophenol-xylylene methods for the determination of ascorbic acid have resulted in an improved procedure with increased specificity. Peroxide treatment is advocated to eliminate interference when sulfite, iron, or tin is present in any of the samples, while a formaldehyde treatment successfully eliminates the interference produced by reductones and related compounds.

Interference due to some sulfhydryl and quinol compounds has been tested. Pyrogallol and hydroquinone at a 10 : 1 molar ratio with ascorbic acid were found to give 25 to 50 percent increases in the ascorbic acid values obtained. No method of correcting the error due to these substances has been elaborated.

**The determination of ascorbic acid in small amounts of blood serum,** O. H. LOWRY, J. A. LOPEZ, and O. A. BESSEY (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 609-615).—Modifications in the dinitrophenylhydrazine method of Roe and Kuether (*E. S. R.*, 90, p. 297) have been worked out to permit the determination of ascorbic acid in 0.01 cc. of serum. Small amounts of blood are collected according to the procedure of Lowry and Hunter (*E. S. R.*, 94, p. 423).

Values obtained were found to be in good agreement with those obtained by the macroindophenol method of Mindlin and Butler (E. S. R., 80, p. 728). The described micromethod is considered particularly suitable for nutritional surveys because of (1) the ease of obtaining suitable blood specimens, (2) the stability of the specimens, and (3) the convenience for large-scale analytical operations.

**Determination of vitamin C in the presence of interfering reducing substances—selective oxidation-reduction method,** A. P. STEWART, JR., and P. F. SHARP (*Indus. and Engin. Chem., Analyt. Ed.*, 17 (1945), No. 6, pp. 373-376, illus. 1).—The analysis of true vitamin C is based upon the use of selective oxidation and reduction procedures carried out under well-defined conditions of pH, time, and temperature.

Ascorbic acid and interfering reducing substances are catalytically oxidized by the addition of concentrated (12 : 1) cucumber juice. Specific reduction of all dehydroascorbic acid to ascorbic acid is obtained by treatment with a suspension of *Escherichia coli* or *Staphylococcus albus*. This ascorbic acid is derived from the dehydroascorbic acid produced by the action of the cucumber oxidase and from any preformed dehydroascorbic acid present in the sample. The indophenol dye titration method is used to measure the total vitamin C present. Assays have been made on canned orange, grapefruit, pineapple, apple, parsley, lettuce, and sauerkraut juice; fresh, evaporated, and dried milk; and blood and urine. A high proportion of interfering reducing substances was found in urine, evaporated milk and parsley, lettuce and sauerkraut juice.

**The chemical determination of tocopherols in animal fats: The stability of hog fats in relation to fatty acid composition and tocopherol contents,** J. R. CHIPAULT, W. O. LUNDBERG, and G. O. BURR. (Univ. Minn.). (*Arch. Biochem.*, 8 (1945), No. 2, pp. 321-335, illus. 3).—The authors point out that the red orthoquinones produced by the nitric acid oxidation of tocopherols have only a moderate intensity of color, and that other substances often present in fats yield oxidation products of which the absorption spectra are such as to interfere with a simple colorimetric determination of tocopherols by this means. Oxidizing the unsaponifiable matter from the extracted fat with nitric acid and separating the red orthoquinones by means of an alumina adsorption column improved the specificity greatly but did not improve the sensitivity. The authors therefore added the further modification of bringing the purified orthoquinones into reaction with the leuco reduction product of methylene blue, prepared and used out of contact with atmospheric oxygen, and determining colorimetrically the dye regenerated by the oxidizing action of the quinones. A great increase in sensitivity was thus obtained, and the small quantities of tocopherols present in animal fats could be measured.

The method was applied to the measurement of tocopherols in hog fats. Evidence obtained indicated that tocopherol concentrations in several fats from the same hog are quite similar, but that the contents of the same fats in different hogs may vary widely. All of the values for several fats from two hogs were considerably greater than a single value previously reported. It was found that, in general, the keeping qualities of carefully processed hog fats are dependent primarily on two factors, their linoleic acid and tocopherol contents. It is concluded that tocopherols are the only natural direct inhibitors of oxidation present appreciably in normal hogs and that the tocopherols are probably derived solely from the diet.

**A simplified hydrogenation technique for the determination of blood plasma tocopherols,** M. L. QUAIFFE and R. BIEHLER (*Jour. Biol. Chem.*, 159 (1945),

No. 3, pp. 663-665, illus. 2).—A simplification of the Quaife and Harris method (E. S. R., 93, p. 680) for the analysis of vitamin E in plasma is reported. By the use of a semimicrohydrogenation apparatus, which is described in detail, analysis of vitamin E can be made in 30 min. Illustrations and suggestions are given for the application of the apparatus to general laboratory hydrogenation.

## AGRICULTURAL METEOROLOGY

The design and analysis of methods for sampling microclimatic factors, H. G. WILM. (U. S. D. A.). (*Jour. Amer. Statis. Assoc.*, 41 (1946), No. 234, pp. 221-232).—"The purpose of this paper is to outline the principles and use of a method for sampling factors—such as the amount of rain reaching the ground under a forest during a series of storms—which exhibit variations in both space and time. Solutions of two somewhat different sampling problems are discussed. One is designed simply to provide a sample estimate (average or sum) for any desired factor over a period of time. The other, with little loss of efficiency, provides a sample estimate for each of a series of short-time units making up the period, as well as an estimate for the period as a whole. It is shown that these sampling methods are likely to supply a substantial gain in efficiency as compared to methods that have been commonly employed."

The glacial anticyclone theory examined in the light of recent meteorological data from Greenland, I. F. E. MATTHES (*Amer. Geophys. Union Trans.*, 27 (1946), No. 3, pp. 324-341, illus. 3).—The glacial anticyclone theory is today still the only definitely formulated theory concerning the atmospheric movements occurring over an ice sheet of large extent. In this paper the author first analyzes the theory and then presents the facts of observation now at hand—especially those reported from the fixed meteorological stations maintained in the interior of Greenland during the 1930's. In this, the first part of the paper, the meteorological data from Eismitte station of the German Wegener expedition are reviewed; the second part is to cover the aerological data of that expedition and similar material from other ice-cap stations. The conclusions reached are that there is now no evidence of a virtually permanent "glacial anticyclone" centered over the Greenland ice sheet; on the contrary, there is consistent evidence from all parts of Greenland that the weather over the ice sheet is controlled by alternating cyclonic and anticyclonic movements. Cyclonic activity is most intense in southern and weakest in northern Greenland. The entire ice sheet is supplied with snow brought by rising maritime masses, not by air descending from the upper troposphere. There is not so much as a 50 : 50 chance of meeting good weather over central Greenland, except for a few weeks in midsummer.

Regional contrasts in hot degree-day units in the United States, S. S. VISHNER (*Amer. Geophys. Union Trans.*, 27 (1946), No. 3, pp. 348-349, illus. 5).—The maps presented—based on official data—reveal sharp contrasts in the intensity and duration of high temperatures and in the need for artificial house cooling if maximum comfort and intellectual activity are to be attained.

The Hale double solar-cycle rainfall variation in western Canada, S. HANZLIK (*Amer. Met. Soc. Bul.*, 27 (1946), No. 5, pp. 249-250).—A brief note.

Experimental maximeters for wind speed, R. L. IVES (*Amer. Met. Soc. Bul.*, 27 (1946), No. 5, pp. 224-228, illus. 4).—It is concluded from the experiments reported that maximeters for station use, designed to operate from a standard anemometer, are relatively expensive and complicated. The follower

type seems mechanically and electrically superior to the direct ratchet type and is less costly in the long run. Cascading of stepping switches to produce a maximeter composed only of stock switches is a useful expedient but does not appear practicable for station use. Work here reported indicates that the follower type is the best to date, but suggests that some new principle—not here covered—may lead to the final answer.

**Further remarks on early uses of punched cards in meteorology and climatology**, L. W. POLLAK (*Amer. Met. Soc. Bul.*, 27 (1946), No. 5, pp. 195–199).—Some comments, with brief summaries of further meteorological and geophysical papers the results of which have been derived by the punched-card method and which were not mentioned in George's article (*E. S. R.*, 93, p. 250).

**Our changing climate**, J. B. KINCER (*Amer. Geophys. Union Trans.*, 27 (1946), No. 3, pp. 342–347, *illus.* 9).—In a previous paper (*E. S. R.*, 70, p. 744), the author discussed long-time temperature trends and presented data showing that an unusual and extended warm phase of climate had at that time developed through a more or less regular rise in temperature for a comparatively long period of years. Up to the end of 1945, records for 13 subsequent years have become available. These are here presented, supplementary to the original data, to determine the tendencies since 1932; they show that the general upward trend continued for several years, but that the more recent records reveal a leveling off and even contain currently a suggestion of an impending reversal. The detailed data are presented and summarized graphically in nine figures.

**The climate of Arizona**, H. V. SMITH (*Arizona Sta. Bul.* 197 (1945), pp. 112+, *illus.* 14).—In 1930 a compilation of weather records for the State was published (*E. S. R.*, 63, p. 416); at that time there were about 90 co-operative stations assisting the U. S. Weather Bureau in recording observations for the area. The present contribution reports figures ending in 1940 from over 175 cooperative Arizona stations and values from over 40 stations established since that date. The principal factors influencing the State's climate are latitude, altitude, interfering mountain ranges, and remoteness from any large body of water. The textual matter (pp. 1–32) includes discussions of the climate, temperature, length of growing season, precipitation over the State, at the university, and at 222 stations, rainfall intensity records, snowfall, relative humidity, sunshine, wind, evaporation climate in relation to comfort, health, and agriculture, and irrigated agriculture. The balance of the bulletin is taken up with some 27 tables presenting detailed statistics of all phases of Arizona weather and climate.

**Climates of Texas**, R. J. RUSSELL. (*La. State Univ.*). (*Tex. Geog. Mag.*, 9 (1945), No. 2, pp. 16–27, *illus.* 2).—Noted from another source (*E. S. R.*, 93, p. 681).

**Weather injuries to fruits and fruit trees**, A. B. GROVES (*Virginia Sta. Bul.* 390 (1946), pp. 39, *illus.* 15).—The weather conditions most commonly responsible for tree and fruit damage are the extremes of temperature and rainfall, and frost, hail, and wind. The principal types of damage caused by unfavorable weather are here discussed and illustrated in an attempt to aid fruit growers in recognizing such injuries as they occur under Virginia conditions.

**North Atlantic hurricanes and tropical disturbances of 1945**, H. C. SUMNER (*Mo. Weather Rev.* [*U. S.*], 74 (1946), No. 1, pp. 1–5, *illus.* 1).—The author presents reviews of all North American hurricanes and tropical disturbances—10 in number—that occurred during the 1945 season, a tabulated synopsis of their important features, and their tracks as plotted on a chart.

**The evolution of rain**, W. J. HUMPHREYS (*Jour. Franklin Inst.*, 241 (1946), No. 6, pp. 391-396).—"To most of us, perhaps, the way nature produces a shower of rain may seem to be too obvious to merit a second thought." The purpose of this article is to explain the evolution of rain and to show why the number of its drops is so small in comparison with that of the condensation nuclei in the lower free air.

**Precipitation in Tennessee River Basin, annual 1945** ([*Washington 25, D. C.*]: *Tenn. Valley Authority*, [1946], pp. 38+, illus. 17).—Detailed statistical data—including maps showing precipitation for the year and by months—are presented.

**Monthly Weather Review [January-March 1946]** (*Mo. Weather Rev.* [U. S.], 74 (1946), Nos. 1, pp. 23, illus. 12; 2, pp. 25-42, illus. 11; 3, pp. 43-61, illus. 11).—In addition to meteorological, climatological, solar radiation, and sun-spot data in each number, No. 1 contains an article noted on page 629.

**Applications of climatology to building construction and agriculture**, C. F. SABLE (*Amer. Met. Soc. Bul.*, 27 (1946), No. 5, pp. 210-215).—Under the stimulus of war an aggressive attitude on the part of climatologists became necessary; the new climatology has come to grips with the practical operating problems requiring climatic information for solution. The author discusses the applications to building construction and to agriculture. During the 1930's there were two distinct developments in the latter field that emphasized the trend away from broad generalizations and superficial methods: One was the interest in microclimatology and the other the establishment of field-plot experiments for determining the effects of weather on the growth and yield of such crops as cotton, corn, winter and spring wheat, and tobacco. Further discussion considers climatology in relation to farm management, land utilization, and the planning of agricultural experimental programs. Finally, a program is presented for the development of agricultural climatology which involves a close cooperation between the U. S. Weather Bureau and the agricultural colleges and experiment stations; "each has what the other needs."

## SOILS — FERTILIZERS

**Forest soils and forest growth**, S. A. WILDE (*Waltham, Mass.: Chron. Bot. Co.*, 1946, pp. 241+, illus. 45).—This book originated from material used for student instruction, including graduates and upper classmen in soils, forestry, botany, game management, and landscape architecture. The subject of forest soils is treated broadly and in relation to contributions from soil science and forestry. Special attention is directed to the genetic soil groups of the world in relation to natural acclimatizational units. The scope of the subject matter presented is indicated by the following chapter headings: Historical and introductory; genesis of forest soils; genetic soil groups of the world—upland soils and hydromorphic and embryonic soils; forest cover—its biological structure and its relation to environment; physical properties, chemical properties, and organisms of forest soils; forest humus; soil-forest types; forest soil survey; soils and tree planting; amelioration of forest soils; silvicultural cuttings in relation to soils; productivity of forest soil and forest management; establishment of forest nurseries and control of nursery watering; use of commercial fertilizers and lime, composts, liquid fertilizers, and green manure crops in forest nurseries; adjustment of nursery soil fertility; and control of parasitic organisms in soils of forest nurseries. A considerable volume of reference material is presented.

**Investigations in erosion control and reclamation of eroded sandy clay lands of Texas, Arkansas, and Louisiana at the conservation experiment station, Tyler, Tex., 1931-40, J. B. POPE, J. C. ARCHER, P. R. JOHNSON, A. G. MCCALL, and F. G. BELL. (Coop. Tex. Expt. Sta.). (U. S. Dept. Agr., Tech. Bul. 916 (1946), pp. 76+, illus. 20).**—This continues a series of bulletins presenting the results from soil conservation experiment stations (E. S. R., 93, p. 401). Results of 10 yr. of research relating to soil and water conservation in the Texas-Arkansas-Louisiana Sandy Lands region on the effect of such factors as rainfall characteristics, soil series, slope, plant cover, cropping systems, strip cropping, terracing, and land use on soil and water losses are reported.

The results have shown that erosion control can be obtained on erodible lands of the region if they are placed under permanent cover of grass or forest. Sloping, intensively cultivated fields, on the other hand, require not only the use of improved rotations and protective winter cover crops but the additional support of terraces. This condition will hold true as long as the prevailing agriculture of the region remains primarily one of growing cotton, corn, and truck crops that require intensive cultivation, which is conducive to soil erosion. The need for terracing and terrace maintenance in the area will make the progress of erosion control slower than if purely vegetative control measures could be used. Subsoils erode more rapidly than the normal topsoils when planted to clean-tilled crops. As the soil becomes thinner the rate of erosion increases, which indicates the need for more intense erosion-control measures on the thinner soils. The Nacogdoches soil is less erodible than the Kirvin series under the same crop and cultural treatments and as a general rule is more productive. Increasing the slope gradient from 8.75 to 16.5 percent increased the soil loss 2.5 times. The kind of crop to be grown determines largely the degree of slope which may be used without excessive soil losses. In general, the utilization of steep slopes should be confined to perennial crops having a high degree of erosion resistance.

Complete control of erosion was not obtained from contour tillage, crop rotations, winter cover crops, or strip cropping alone or in combination, although marked reductions in soil losses were obtained as compared with those on the check area. Strip cropping reduced soil losses but did not furnish protection adequate for continued cropping of the field. The crop grown and the width and location of the strip are important factors in the successful use of strip cropping. When used in combination with terraces, strip cropping helped to reduce soil loss where the strip was located immediately above and including the terrace channel. Soil losses from terraces having grades exceeding 3 in. per 100 ft. were excessive. Terraces occupying fields having a deep, porous soil may be laid out with less grade than those on badly eroded fields having an impervious subsoil, and open-end, level terraces may be used on gentle, well-drained slopes where the soil has an exceptionally high infiltration rate. Much care, however, should be exercised in their construction and maintenance. Closed-end, level terraces should not be used, owing to the high intensities of the rainfall of the region.

The authors point out that owing to the widely diversified agriculture of the region, its small farms, and the character of the rainfall, any land use or conservation program adopted will have to possess sufficient flexibility to meet the particular requirements of the individual farm operator if it is to obtain any degree of success. There is little hope of changing the basic system of agriculture in the region as long as the present economic system prevails, nor is such a change desirable. Localized modifications of the agricultural sys-

tem have been observed in different parts of the area during the period of experimentation, but have not been of sufficient extent to warrant a change of recommended land use practices. The production of fruit and vegetable crops together with dairy and poultry products enables the average farmer to attain a high degree of self-sufficiency. This is an asset of almost inestimable value to an erosion-control or land use program. The growing of fruit and vegetable crops, however, requires intensive cultivation. This subjects the land on which these crops are grown to serious erosion unless appropriate conservation measures are applied. And finally, a wise land use program for the problem area calls for retiring the steeper slopes from cultivation, terracing the more gently sloping cultivated areas, and adopting appropriate and effective agronomic practices for the terraced fields in order to maintain their productivity and to further protect the soil from erosion.

**Effect of soil treatment on soil productivity: A summary of long-time field experiments.** F. C. BAUER, A. L. LONG, C. J. BADGER, L. B. MILLER, C. H. FARNHAM, P. E. JOHNSON, L. F. MARRIOTT, and M. H. NELSON (*Illinois Sta. Bul. 516 (1945), pp. 106-224+, about 10 illus.*).—This bulletin presents a comprehensive account of the effect of soil treatment on soil productivity as determined by numerous long-time field experiments conducted in various sections of the State. Data are presented in 85 tables on the effect of soil treatments on different crop yields under various soil types. Nine systems of soil treatments were established on each of the Illinois experiment fields when they were laid out, four designed for livestock farming and five for grain farming. These systems, involving a step-by-step build-up from no treatment to somewhat complex combinations, have been maintained with but little change to date. Detailed information is given on soil conditions on the several test fields. On a poor soil a complete treatment consisting of the use of crop residues, limestone, rock phosphate, and potash produced an average yearly income per acre for the 35-year period 1910-44 of \$18.89, while under a system involving no soil treatment the yearly return was only \$3.97. On one of the most productive soils good land treatments have been responsible for a much smaller share of crop yields than on the poor land. For the good soil, average yearly income for the period indicated above for the complete soil treatment was \$26.10 while with no soil treatment the return was \$23.32.

**The effect of mineral supply on the mineral concentration and nutritional quality of plants.** K. C. BEESON. (U. S. D. A.). (*Bot. Rev. 12 (1946), No. 7, pp. 424-455, illus. 1*).—This extensive review (124 references) considers the effects of various fertilizer elements on the P and Ca contents of plants, the effects of micronutrients on the mineral composition of plants, investigations with nutrient solutions, and the effects of fertilization on the quality of forages as measured in terms of animal growth and health. A number of generalized conclusions developed from the published data are presented and discussed.

**Fertilizers and lime in the United States: Resources, production, marketing, and use.** F. W. PARKER, J. R. ADAMS, K. G. CLARK, K. D. JACOB, and A. L. MEHRING (*U. S. Dept. Agr., Misc. Pub. 586 (1946), pp. 94+, illus. 23*).—The resources, production, marketing, and use of fertilizers and lime are reviewed and discussed. The information is presented to serve as basic material in the formulation of a national policy with respect to fertilizer use. A list of over 100 selected references is appended.

**Preparation of ammonium nitrate for use as a fertilizer.** W. H. ROSS, J. R. ADAMS, J. Y. YEE, C. W. WHITTAKER, and K. S. LOVE (*U. S. Dept. Agr., Tech.*

*Bul. 912 (1946), pp. 80, illus. 13*).—Although considerable attention has been directed recently to ammonium nitrate as a fertilizer, it cannot be considered a new fertilizer material except when used directly as such. As a fertilizer material it has been sold in the form of products known as Nitrogen Solution, Leunaspeter, and Cal-Nitro. It has been produced commercially by the methods of crystallizing, graining, and spraying. Each particle of monocrystalline ammonium nitrate as obtained in the most recent methods of preparation consists of a single crystal, whereas the particles of sprayed or grained material consist of aggregates of crystals. The grained ammonium nitrate is about twice as porous as the monocrystalline material and the sprayed material about five times as porous. These differences in porosity have a marked effect on the capacity of the different types of ammonium nitrate to hold absorbed moisture and on their tendency to cake under varying climatic conditions. A slight change in moisture content has a greater effect on the caking of ammonium nitrate than a corresponding small change in any of the other factors that affect its tendency to cake. The most effective conditioning agents for reducing caking are Celite, Dicalite, Kittitas and other forms of kieselguhr, kaolin and other types of clay, plaster of paris, and tricalcium phosphate. The most effective water repellents for decreasing the rate of moisture absorption from the air are mixtures of paraffin with petrolatum or asphaltum and of petrolatum and paraffin with asphaltum or rosin.

Tests under carefully controlled conditions with standard farm equipment indicate (1) that the drillability of any given material increases with the uniformity of its particle size; (2) that the sprayed ammonium nitrate now on the market is more drillable than the grained material, owing to differences in particle size; and (3) that granular ammonium nitrate that has been treated with a water repellent and a conditioning agent is more drillable under conditions of high humidity than when treated with a conditioning agent alone. Although a double treatment with a water repellent and a conditioning agent greatly improves the drillability of ammonium nitrate under conditions of high humidity, the use of a water repellent is not considered necessary in sections where the prevailing humidity is relatively low. Bags now on the market are capable of maintaining properly conditioned ammonium nitrate in a satisfactory mechanical condition for at least a year in the most humid sections of the country.

**Placement of nitrogen fertilizer for corn and oats, J. PITNER** (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, pp. 1,7).—Experiments on rates, methods of application, and sources of nitrogen for cotton and corn showed that plow sole application produced a significantly higher yield of cotton and corn than the furrow, side-dress, or deep method of application.

## AGRICULTURAL BOTANY

**Elementary bacteriology, J. E. and E. O. GREAVES** (*Philadelphia and London: W. B. Saunders Co., 1946, 5. ed., [rev.], pp. 613+, illus. 169*).—In this edition of the textbook previously noted (*E. S. R.*, 84, p. 23) a chapter on antibiotics has been added; many chapters have been completely rewritten and nearly all have been greatly modified.

[The effects of various chemicals on bacteria and fungi—particularly yeasts] (*Compt. Rend. Lab. Carlsberg, Sér. Physiol.*, 24 (1946), No. 12–17, pp. 133–184, illus. 1).—The following papers are included: The Influence of  $\alpha$ ,  $\gamma$ -Dihydroxy- $\beta$ ,  $\beta$ -Dimethyl-Butyric Acid on Yeast Growth, by V. Hartelius and G. Johansen (pp. 133–140); Antivitamin Effect on Sulfanilamide on

*Saccharomyces cerevisiae* (pp. 141-155), Antivitamin Effect of Sulfanilamide on *Streptobacterium plantarum* (pp. 156-162), and Effect of Marfanil on *Streptobacterium plantarum*, *Saccharomyces cerevisiae*, and *Aspergillus niger* (pp. 163-171), all by V. Hartelius and K. Roholt; Effect of Benzoic Acid and Benzoic Acid Derivatives on the Growth of *Streptobacterium plantarum* and *Saccharomyces cerevisiae*, by K. Roholt (pp. 172-177); and Antivitamin Effect of Sulfanilamide on *Aspergillus niger*, by V. Hartelius (pp. 178-184).

[Papers in bacteriology] (*Jour. Bact.*, 51 (1946), No. 5, pp. 576-577, 595, 599-600, 635-636).—The following miscellaneous abstracts are included: Mechanism of Pyridoxal Phosphate Function in Bacterial Transamination, by W. W. Umbreit, D. J. O'Kane, and I. C. Gunsalus (Cornell Univ.); The Production of Fungal Amylases in Submerged Culture and Their Use in the Production of Industrial Alcohol, by J. M. Van Lanen and E. H. LeMense (U. S. D. A.); Commercial Inoculation of Legume Seed, by F. S. Orcutt and A. L. Whitman (Va. A. and M. Col.); and The Relationships of the Gram-Negative, Nonsporeforming, Peritrichous Bacteria to Nonmotile Bacteria, by R. S. Breed (N. Y. State Expt. Sta.).

Class bacteriological filters arranged for positive pressure, M. T. BUSH (*Jour. Bact.*, 51 (1946), No. 4, pp. 531-532, illus. 1).—In spite of the advantages of positive pressure filtration in both chemical and bacteriological work, negative pressure seems to be used almost universally in the laboratory. Various set-ups tried by the author were not entirely satisfactory because the compressed air leaked out. It was not until Corning UF filters became available recently that it was feasible to construct an apparatus with ground joints. The set-up described and illustrated has proved satisfactory; in the author's experience it does not let bacteria through during prolonged filtrations if the solutions being filtered do not provide good growing conditions. When such a solution does provide a good bacterial medium, the pressure filter may be set up in the ice box. If the filter is washed with distilled water immediately after use, ordinary air-borne contaminants apparently cannot "grow through" the filter.

The bacteriophage as a means of identifying bacteria, R. C. THOMAS (*Ohio Sta. Bul.* 659 (1945), pp. 175-176).—In this study the phage reaction was found to be useful for species identification in bacteria pathogenic to both plants and man; 10 species in all were used.

Ultrasonic disintegration as a method of extracting bacterial enzymes, P. K. STUMPF, D. E. GREEN, and F. W. SMITH, JR. (*Jour. Bact.*, 51 (1946), No. 4, pp. 487-498, illus. 2).—The authors describe a technic for disintegrating bacterial cells by ultrasonic radiation, employing the method to prepare cell-free extracts of bacterial enzymes. A number of factors influencing the degree of efficiency of ultrasonic disintegration are discussed.

Influence of incubation temperatures on differential tests of coliform bacteria, J. E. FULLER. (Mass. Expt. Sta.). (*Jour. Bact.*, 51 (1946), No. 4, pp. 457-464).—Coliform cultures isolated from rural water supplies were studied to determine the effects of incubation at 37°, 40°, 44°, and 46° C. on their reactions to differential tests. Only *Escherichia coli* produced gas effectively in lactose broth at 46°; this test was selective only for indole-positive *E. coli*, as contrasted with the other strains studied. Endo's medium plates were streaked from lactose broth cultures incubated at the several temperatures; these—incubated at 37°—showed typical results for *E. coli* throughout the temperature range employed, but results for other strains were variable and lacked definition. The methyl red test at 44° indicated a definite relationship of all *E. coli* and *Citrobacter* strains, including those that were indole-negative; the number of positive tests declined substantially at 46°. The Voges-

Proskauer and sodium citrate tests gave no significant information above 37°. The findings suggest that the methyl red test at 44° may prove useful as a confirmatory test for evaluating the sanitary significance of atypical or intermediate strains of coliform bacteria isolated from raw water.

**A procedure for the characterization of acetic acid bacteria,** J. TOSIC and T. K. WALKER (*Brewers Digest*, 21 (1946), No. 7, pp. 31-34, 39, illus. 5).—The acetic acid bacteria are important beer spoilage organisms which, if left unrecognized and uncontrolled, may cause serious losses by rendering the beer sour andropy. A number of species isolated from brewers' yeast and beer have been described in the literature (7 references). In this paper consideration is given to the precautions necessary in standardizing the conditions for examining cultures of *Acetobacter* spp. in order that comparisons may be obtained for diagnostic purposes. The media and technic employed are described in detail, and particulars are given of 10 species examined under the standardized conditions adopted.

**Capsule formation by *Acetobacter* species,** D. KULKA and T. K. WALKER (*Jour. Inst. Brewing*, 52 (1946), No. 3, pp. 129-131, illus. 3).—The authors found that although most of the methods available for staining bacterial capsules gave negative results when applied to the "acetic acid bacteria," Baker's procedure served admirably to demonstrate the presence of encapsulated cells in cultures of these organisms. Gin's technic was also found entirely suitable; when applied to cells of 14 species of *Acetobacter*, it revealed the presence of capsules in every case. It is believed probable, therefore, that capsule formation is a characteristic of species of this genus.

***Acetobacter* infection.—III, A study of strains of *Acetobacter acetosum*, isolated, respectively, from "pitching" yeast and from beer,** D. KULKA, J. TOSIC, and T. K. WALKER (*Jour. Inst. Brewing*, 52 (1946), No. 3, pp. 132-135, illus. 2).—In studies of *Acetobacter* spp. liable to occur as contaminants in brewery products, an examination was made of two strains of acetic acid bacteria—one isolated from the pitching yeast of a brewery and the other from a sample of sour beer from another brewery; both were found to be strains of *A. acetosum*, a vinegar organism that undoubtedly can establish itself under favorable circumstances as a nuisance in beer breweries. To distinguish these two strains, they are here designated as Y and B strains of the species; these strains are compared with an authentic culture of the type organism, *A. acetosum*.

**Aerobic mesophilic sporeforming bacteria,** N. R. SMITH, R. E. GORDON, and F. E. CLARK (*U. S. Dept. Agr., Misc. Pub.* 559 (1946), pp. 112, illus. 3).—The authors studied 621 cultures of aerobic mesophilic sporeformers, of which 363 bore specific names and 258 were unnamed. These cultures were placed in 3 groups on the basis of their morphology and physiology. For separating certain species, a modified Voges-Proskauer test proved reliable. Fat storage and the fermentation of C compounds in the presence of inorganic N were studied extensively. Of special significance was the ability of certain strains to produce adaptive enzymes so that carbohydrates not regularly attacked could be utilized; in many cases this ability was lost after a few months' storage in the absence of the particular carbohydrate. Agglutination by antisera produced with whole cells as antigens and lysis by some bacteriophages were too specific for taxonomic use. Other phages—especially for *Bacillus megatherium*, *B. cereus* and its varieties, *B. pumilus*, and *B. brevis*—proved very useful. By inducing variations in certain strains of a species and/or observing similar variations as they existed among strains in the collection, a "species pattern" was developed in each case. It was found that

many species previously described and separated from others were merely growth stages of established species, and that others were biotypes or morphotypes of the "parent species"; consequently, a large number of named cultures have been placed in the synonymy of the accepted species, which has resulted in a reduction from about 120 to 15 specific names. A dichotomous key is given in which two characters instead of one are—insofar as possible—used at each separation. A variation or misinterpretation of one of these should not, therefore, lead to a wrong conclusion. There are 119 references.

**Subtilin—an antibiotic produced by *Bacillus subtilis*.** I, II, A. J. SALLE and G. J. JANN. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 60 (1945), No. 1, pp. 60–64, illus. 2; 61 (1946), No. 1, pp. 23–24, illus. 1).—Two papers are presented:

I. *Action on various organisms.*—This antibiotic was found active against gram-positive bacteria and against *Neisseria* of the gram-negative group; acidfast organisms, including *Mycobacterium tuberculosis*, were likewise susceptible to it. It produced a bacteriostatic action in high dilution and a germicidal effect in greater concentration. A number of pathological higher fungi were also found susceptible to subtilin.

II. *Toxicity of subtilin to living embryonic tissue.*—In this contribution, two notable exceptions to the usual action of this antibiotic are stressed, viz, *N. catarrhalis* and *N. gonorrhoeae*—both gram-negative—which are antagonized by subtilin. The antibiotic exhibited an extremely low toxicity for embryonic chick heart tissue fragments cultured in vitro. Under the test conditions subtilin was about 20 times more toxic to *Staphylococcus aureus* than to chick heart tissue.

**Rapport entre la production d'anhydride carbonique et l'activité bactériostatique du *Penicillium notatum* culture superficielle** [Relation between the production of CO<sub>2</sub> and the bacteriostatic action of *P. notatum* in surface culture], M.-M. JANOT, H. PENAU, H. VELU, G. BOUET, M. CHAIGNEAU, and M. CHOIX (*Compt. Rend. Acad. Sc.* [Paris], 222 (1946), No. 18, pp. 1054–1056).—It is concluded that the rate of evolution of CO<sub>2</sub> into the air surrounding the culture is no indication of the bacteriostatic activity of the *P. notatum* crop.

**Penicillin production by a superior strain of mold**, M. J. JOHNSON, J. J. STEFANIAK, F. B. GALEY, and B. H. OLSON. (Univ. Wis.). (*Science*, 103 (1946), No. 2678, pp. 504–505).—The figures in this note represent a small part of the data obtained during an investigation of the factors influencing fermentation time and yield of penicillin in submerged cultures. The results obtained when a number of penicillin-producing mold cultures were tested in 80-gal. tanks are summarized. The superior strain of mold is referred to as No. X-1612.

**Production of penicillin X in "submerged" surface cultures**, E. STICE and R. PRATT (*Science*, 103 (1946), No. 2678, pp. 535–537, illus. 2).—The unit described and illustrated was originally devised to incorporate in surface cultures the advantages of the deep-vat method of fermentation; cultures grown in it have consistently yielded relatively large proportions of this antibiotic. The apparatus is simple in design and easily constructed and is said to produce a continuous supply of penicillin for several weeks without resterilization or reinoculation.

**Microbiological aspects of penicillin.**—IV, **Production of penicillin in submerged cultures of *Penicillium notatum***, J. W. FOSTER, H. B. WOODRUFF, and L. E. MCDANIEL (*Jour. Bact.*, 51 (1946), No. 4, pp. 465–478, illus. 1).—In this paper of the series (E. S. R., 93, p. 128).—temporarily held up from pub-

lication by "a U. S. Government secrecy order"—it is shown that growth of suitable *P. notatum* strains in shake culture (submerged growth developed by agitation and aeration) leads to the rapid formation of potent penicillin broths. This procedure is said to have numerous advantages over surface cultures; among them, the variable factors of diffusion and pellicle formation are eliminated, and growth and metabolic processes are accelerated. A determining factor in submerged culture work is the selection of a suitable strain of mold. Penicillin formation occurs in shake cultures in a nearly synthetic medium in which brown sugar supplies certain substances essential for growth and penicillin formation. Crude organic supplements hasten the development of *P. notatum* and increase the maximum penicillin titer yielded. Corn steep liquor serves as an excellent supplement, provided its reserve acidity is adjusted with NaOH, CaCO<sub>3</sub>, or both. Sugar concentration has but slight effect on penicillin formation; maximum production was obtained after the disappearance of sugar from the medium. Other organic supplements—particularly cottonseed meal—promoted penicillin formation in the same way as corn steep. Evidence is presented that there are two factors promoting penicillin production—one organic and the other inorganic; brown sugar contains both, and cottonseed meal contains at least the organic factor. Of paramount importance in the production of penicillin in submerged cultures is the maintenance of an adequate O<sub>2</sub> supply.

**Gladiolic acid: An antifungal and antibacterial metabolic product of *Penicillium gladioli*** McCull and Thom, P. W. BRIAN, P. J. CURTIS, J. F. GROVE, H. G. HEMMING, and J. C. MCGOWAN (*Nature [London]*, 157 (1946), No. 3995, pp. 697-698).—A preliminary account.

**Brazilian chytrids.**—VIII, Additional parasites of rotifers and nematodes, J. S. KARLING (*Lloydia*, 9 (1946), No. 1, pp. 1-12, illus. 53).—The new species *Olpidium granulosum* and *O. rotiferum* are described and illustrated as parasitizing rotifer eggs and adults.

**Brazilian chytrids.**—IX, Species of *Rhizophydium*, J. S. KARLING (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 338-334, illus. 37).—In continuation of this series (see above) 12 species of this fungus were isolated from water and moist soil samples; of these 7 are new—3 of them hyperparasites of Oomycetes, Zygomycetes, and other chytrids, 3 parasitizing microscopic animals, and the others attacking algae, fern spores, and pollen grains.

**Pure cultures of algae, their preparation and maintenance**, E. G. PRINGSHEIM (*Cambridge, Eng.: Univ. Press*, 1946, pp. 119+, illus. 9).

**Plant-hunting in China: A history of botanical exploration in China and the Tibetan marches**, E. H. M. COX (*London: Collins Clear-Type Press*, 1945, pp. 230, illus. 28).

**The estimation of ground conditions from aerial photographic interpretation of vegetation types**, R. N. COLWELL (*Photogrammetric Engin.*, 12 (1946), No. 2, pp. 151-161, illus. 9).—The engineer, forester, or geologist contemplating ground reconnaissance of an area unfamiliar to him can profit greatly by detailed advance information based on aerial photographs. For example, it appeared that within a certain area a shallow and fertile layer of topsoil was underlain by a very porous substrate which reduced surface run-off to a minimum. Various examples of vegetation identification are also presented, and the use of this technic for military purposes is discussed.

**Plant immigrants and stowaways—their romantic story**, A. MCTAGGART (*Melbourne: Lothian Pub. Co.*, 1945, pp. 62+).—"It has been the aim of the writer of this small volume to gather together and recount as many as possible of the interesting stories associated with plant introduction or migration, particularly those exhibiting elements of romance or unusual features."

**The evaluation of taxonomic characters of cultivated Brassica with a key to species and varieties.**—I, The characters, V. G. SUN (*Bul. Torrey Bot. Club*, 73 (1946), No. 3, pp. 244-281, *illus.* 13).—Though much has been published on this genus of the mustard family, workers have been influenced by the demand of economic botanists for a satisfactory agricultural classification; the author believes that the resulting combination of botanical principles and agricultural convenience is responsible for much confusion and that a better classification has long been needed. The evaluation of morphological characters in conjunction with studies of the genetics and cytology of interspecific hybrids has been used in developing a system based primarily on botanical principles. In devising the system presented, he has attempted to use only such characters as are indicative of fundamental differences in genetic constitution: in carrying out this design the following important characters are discussed: Size of pollen grains, hairiness of plant, stem and root characters, shape of foliar organs, glaucescence and color of plant, branching habit, type of inflorescence and of sepals at anthesis, size, shape, and color of petals, length and shape of the silique and its beak, angle between pedicels and rachis, number of seeds per silique, and color and size of seeds.

**Notes on the flora of Taylor County, Texas,** W. L. TOLSTEAD and V. L. CORY. (Univ. Nebr. et al.). (*Field and Lab.*, 14 (1946), Nos. 1, pp. 32-48, *illus.* 3; 2, pp. 49-69, *illus.* 2).

**Notes on the types of some Californian species of Convolvulus,** L. ABRAMS (*Stanford Univ., Dudley Herbarium Contrib.*, 3 (1946), pt. 11, pp. 351-373, *illus.* 4).

**Studies in the Sapotaceae.**—V, The South American species of *Chrysophyllum*, A. CRONQUIST (*Bul. Torrey Bot. Club*, 73 (1946), No. 3, pp. 286-311).—In this further contribution (*E. S. R.*, 94, p. 602), 30 species of *Chrysophyllum* are described, involving considerable new taxonomy; a key to these species is provided.

**Effect of radioactive elements upon development of the root-nodule bacteria and upon the assimilation by them of the molecular nitrogen of the atmosphere,** A. A. DROBKOV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 49 (1945), No. 3, pp. 221-226).—Root-nodule bacteria are, in general, extremely sensitive to deficiencies in individual minor elements; radioactive elements are said to occupy an outstanding place in this respect. When radium or other radioactive elements were carefully eliminated from the nutrient medium no nodules were formed on the roots of peas, even when the medium contained B and Mn and was inoculated with the nodule bacteria. When radium was introduced at  $10^{-10}$  per 1,000 cc. of nutrient solution, the nodule bacteria developed intensely on the roots of young peas and assimilated nearly twice as much molecular N from the air as the controls, even when normal doses of N were contained in the nutrient medium.

**Variation within strains of clover nodule bacteria in the size of nodule produced and in the "effectivity" of the symbiosis,** P. S. NUTMAN (*Jour. Bact.*, 51 (1946), No. 4, pp. 411-432, *illus.* 5).—The author describes studies of the symbiotic behavior of two strains of *Rhizobium* as influenced by host passage and by storage in soil or on agar media. The results refer to mean length and "effectivity" of nodules on red clover grown under bacteriologically controlled conditions. The original culture of the effective strain (A) proved to be uniform for behavior of isolations from replicate colonies, though considerable variation occurred among the responses of individual plants infected from the same colony. Neither plant passage with or without intervening plating or short-time culture on agar nor selection from large or small

nodules had any effect on the mean size or effectivity of the nodules formed by this strain. Similarly, plant passage failed to modify the behavior of the ineffective strain (H. K. C.). On the other hand, after storage of A in sterilized Woburn sandy soil, ineffective variants were found to constitute a considerable proportion of the bacterial population; these variants resembled the parent type in cultural and serological characters. After passage of these ineffective variants through the plant, two reversions to the effective parent type occurred among the 13,400 nodules examined; these remained effective on further host passage. Stock cultures on agar slants—both of the effective type and of the ineffective variant—exhibited an occasional tendency to produce new variants in effectivity. Variants in type of growth on agar also appeared under these conditions. There are 19 references.

**Bacterial root nodules in the Zygophyllaceae**, Y. S. SABET (*Nature [London]*, 157 (1946), No. 3994, pp. 656-657, illus. 2).—A note on the root nodule bacteroids of *Fagonia arabica*, *Tribulus alatus*, and *Zygophyllum* spp. In experiments with *Z. coccineum* appeared to show that these plants cannot thrive unless nodules are developed and that the bacteroids provide the hosts with N.

**Plant physiology in the U. S. S. R.**, E. ASHEY (*Nature [London]*, 157 (1946), Nos. 3991, pp. 558-561; 3992, pp. 596-597).—This "very brief account is incomplete and should not be regarded as critical, but it will give some idea of the variety of work going on and the whereabouts of the principal workers."

**Phycomycetes in the assay of thiamine in agar**, D. DAY and A. H. HERVEY. (Univ. Minn. et al.). (*Plant Physiology*, 21 (1946), No. 1, pp. 233-236).—*P. blakesleeana* was grown on a basal medium of distilled water, minerals, dextrose, and asparagine plus purified agar and thiamine in various proportions and combinations; the mycelium was harvested by the hot and cold water methods, which included use of aluminum pans and Gooch crucibles. With the basal liquid medium, the dry weight of mycelium washed with cold water was higher than that washed with hot water, probably because of the action of the latter in dissolving substances from the fungus. The higher dry weight of mycelium grown on agar and washed with cold water might be explained not only by this action of the hot water but also by the incomplete separation of the agar and the mycelium by the cold water. Reduced growth was generally correlated with an increased amount of agar.

**Parthenocarpy and accompanying hormonal syndromes induced by unrelated chemicals**, L. J. HAVAS (*Nature [London]*, 157 (1946), No. 3993, pp. 629-630).—A note on the author's induction of parthenocarpy in cucumber by ethyl mercury phosphate and acenaphthene and in tomato by colchicine. In addition to giving evidence of induction of parthenocarpy by a mercury compound chemically unrelated to substances previously shown to exhibit that property, he stresses the hormonal effects. Taken together, he believes that the findings confirm the suggestion that there is essentially a common mechanism at work, viz, a disturbance of the vertical polarity of translocation of endogenous hormones and of the hypercompensations resulting therefrom.

**Growth inhibiting action of urine extract on seedlings**, E. D. BRAIN (*Ann. Bot. [London]*, n. ser., 10 (1946), No. 38, pp. 195-202).—Experiments were performed on cut epicotyls of garden pea and broadbean to test the action of urine extract (H 11),  $\beta$ -indoleacetic acid, sodium indoleacetate, and certain anthraquinone derivatives on the growth of lateral buds. H 11 caused marked inhibition of the growth of side shoots and swelling in the cut stems. Treatment with  $\beta$ -indoleacetic acid inhibited the growth of side shoots and swelling

in the cut stems, but a concentration of 6,250 units per gram caused less swelling than H 11 extract. Comparison of the effects of  $\beta$ -indoleacetic acid and sodium indoleacetate showed more swelling in the cut stems after treatment with the sodium salt. Solutions of anthraquinone and the refined sodium salt of anthraquinone disulfonic acid caused inhibition of side shoots and slight increase in the height of cut stems; 1 : 5 dihydroxyanthraquinone gave less growth in the cut stems and increased growth of side shoots as compared with control plants. The findings indicate that the swelling of the stem following application of concentrated solutions of  $\beta$ -indoleacetic acid is independent of the inhibition effect on lateral buds, and also that other substances, such as members of the quinone series, can inhibit the growth of side shoots.

**Etudes sur les enzymes de la fève gourgane (*Vicia faba* L.) pendant la germination,** J. LABARRE and S. PFEFFER (*Rev. Canad. Biol.*, 5 (1946), No. 2, pp. 233-246, illus. 4; *Eng. abs.*, p. 245).—The germinating broadbean was found to contain two amylases, viz,  $\alpha$ -amylase, which attained maximum activity about the eighth day, and  $\beta$ -amylase, which reached its highest activity about the tenth day of germination. The optimum pH for the amylase calculated as  $\beta$ -amylase was 5.3; the optimum temperature, 45° C. The proteases were at their maximum about the eighth day of germination; three were noted at pH optima of 2.05, 4.18, and 7.85; the optimum temperature was 45°. Ascorbic acid determinations indicated the presence of an ascorbic acid oxidase which was at a maximum at the seventh to ninth days of germination. Attempts to find urease were unsuccessful. The rH of the broadbean became more positive during the later stages of germination. There are 24 references.

**Etude microcalorimétrique du développement des cultures bactériennes et de la germination des graines** [Microcalorimetric study of the development of bacterial cultures and of the germination of seeds], H. PRAT, E. CALVET, and J. FRICKER (*Rev. Canad. Biol.*, 5 (1946), No. 2, pp. 247-250, illus. 1; *Eng. abs.*, p. 250).—Using Tian's microcalorimeter, the authors studied the heat production during the course of seed germination and the development of bacterial cultures. In seeds of a variety of plants two distinct phases were observed, viz, one of physicochemical and one of biological thermogenesis; the two phases are compared for the different species and some factors influencing each phase are discussed. In bacteria, each strain was found to have a specific thermogenesis curve; the experimental conditions modifying this curve were studied.

**Growth correlates of electromotive forces in maize seeds,** O. E. NELSON, JR., and H. S. BURR. (Conn. [New Haven] Expt. Sta. et al.). (*Natl. Acad. Sci. Proc.*, 32 (1946), No. 1, pp. 72-84, illus. 5).—For any maize there are said to be two possible potential determinations: (1) The prime potential appears to be highly correlated with seed viability, but with no measured attribute of plant growth; (2) the equilibrium potential is not correlated with seed viability but rather with the inherent genetic constitution of a plant, since by use of the potentiometer and equilibrium potential determinations it becomes possible to segregate from a given population those seeds with superior growth characteristics. Furthermore, these potential differences among seeds were highly correlated with the growth of progeny one generation removed. For these reasons, it is believed that the potentiometer may prove a useful tool for plant breeders.

**Preliminary experiment on the cultivation of *Baeria chrysostoma* under sterile conditions,** S.-W. LOO (*Amer. Jour. Bot.*, 33, (1946), No. 5, pp. 382-

389, *illus.* 4).—By growing plants under sterile conditions certain problems may be studied in a simplified and controlled way. The author shows that *B. chrysostoma* (branchy goldfields) plants can grow to maturity and produce seeds under aseptic conditions; he has found no record in the literature of any higher plant being successfully cultured for a complete life cycle under sterile conditions. Low night temperatures produced the best growth in *Baeria*, irrespective of the daytime temperature; best growth was obtained at 26° C. in the daytime combined with 13° at night. Production of leaves was unaffected by different day or night temperatures, but their width increased with rises in the night temperature. Growth was improved by adding two percent sugar to the nutrient medium; "osmotic adaptation" apparently took place. Nitrate proved the best source of N, but urea was utilized to a considerable extent. Long photoperiod and added sugar accelerated the initiation and production of flowers; these factors had a significant effect on the development of young plants, but flowers were produced under short-day conditions provided the plants were kept in culture long enough.

**Development in sterile culture of stem tips and subjacent regions of *Tropaeolum majus* L. and of *Lupinus albus* L.,** E. BALE (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 301–318, *illus.* 16).—Very small stem tips (A-pieces) and cubes of subjacent maturing tissues (B- and C-pieces) of *Tropaeolum* and *Lupinus* were grown and studied in sterile cultures. The A-pieces utilized the water, sucrose, and mineral salts of the nutrient solution and demonstrated their pronounced capacity for development by growing into entire plants. The stem tip of *Tropaeolum*, having a lower respiratory rate than its subjacent tissues, would grow into a complete plant only beneath the agar; that of *Lupinus*, having the highest respiratory rate of the shoot, would grow into a complete plant only on the agar surface. This behavior indicates that primary meristems cannot all be characterized by low O<sub>2</sub> consumption. The polarity of the stem tips was not altered by inverted or horizontal orientations to gravity; furthermore, the curvatures in various orientations suggested that the shoot apex controls the curvature of the subjacent tissues. Plants grown from the shoot tips contained normal, though small, vascular systems, which had been "determined" by the activities of their shoot apices entirely separated from the influences of the original plant body. According to the author's interpretation, the shoot apex is not merely a plastic region that obeys the impulses sent to it from the mature subjacent regions, but actually controls or "determines" the growth and behavior of the subjacent regions.

The B- and C-pieces grew best in an aqueous medium to which unautoclaved coconut milk had been added. Those of *Lupinus* produced spherical masses that usually grew by cambiumlike zones considerably beneath the original cut surfaces. Internally, this cambium produced parenchyma and very short tracheal elements; externally, it produced parenchyma and some cells that appeared to be sieve-tube elements. By contrast, the subjacent tissues of *Tropaeolum* had various regions of superficial cells that underwent rapid mitoses, the end result being an irregular mass of parenchymatous cells that only infrequently contained groups of tracheal elements. The calluses from neither plant regenerated roots or buds. The original polarity of these subjacent regions was not retained in culture: the calluses were radially differentiated and therefore without polarity. The growth of the B-pieces was always greater than that of the C-pieces, corresponding with earlier findings that the respiratory rate of the B-piece was greater than that of the C-piece.

The results of these studies are interpreted as suggesting that there is a decreasing capacity for growth and development in these small volumes of tissues down the plant axis; this phenomenon is labeled physiological differentiation. It is considered to agree with the suggestions in the literature that not all living plant cells are possessed of "unlimited capacity for development," but that this capacity is restricted to a very few tissues. The shoot is considered to possess in the highest degree the capacities for developing the entire plant; its subjacent tissues, to possess these capacities to only a limited extent. This interpretation is contrasted to other suggestions in the literature (60 references) that theoretically every living plant cell is capable of producing any cell organization characteristic of the species.

**Streaming movements of solutions in plants, D. T. MACDOUGAL** (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 312-328, illus. 5).—According to the author, filaments or liquid in the hydrostatic system of plants may be visualized as a cohesive meshwork occupying conduits in the xylem, rays, and phloem and extending through the moist walls and membranes to the vacuoles of all or nearly all living cells of the plant. Tensions set up in the system by vaporization from cell walls in the leaves cause a flow of many centimeters per hour in nonliving conduits; increasing tensions result in reduced diameter of nonliving elements with collapsible walls and of volume of turgid cells. These variations were greatest in the phloem of the trees examined. Abrupt contractions from accelerated transpiration at sunrise continued for 5 to 7 hr. and were relieved the following 17 to 18 hr. beginning after midday by osmotic action with lessened tensions. The course of movement in the conduits is in the form of a whirlpool, in which the ascending sap constitutes the main stream with the downwardly flowing leaf products being drawn in radially or laterally at all levels to be carried upward. Inequalities of conversion may be followed by upward movements in the phloem. The supposedly phosphorylated carbohydrates formed in the leaves are translocated as such in *Pinus radiata*. Condensation into starch occurs only in the rays. The concentration estimated as glucose is highest in the outermost layer of wood and least in the conduits in which the most rapid movement of sap takes place. Seasonal variations consonant with photosynthetic activity and growth are recognizable. Girdling of *Pinus* cuts a sector of the phloem out of the circulatory system, and the leaf products in the region below the girdle are depleted by being drawn into the xylem. Inactivation of the cambium follows. Growth may be resumed if the supply of leaf products is renewed by translocation across the girdle through callus bridges. Traumatic reactions to girdling include the formation of callus at the upper margin of the denuded zone, inhibition of growth for several days, and a subsequent heavy accumulation of starch in the hypertrophied wood parenchyma in a segment of the trunk known to extend 4 m. above the denuded zone in the Monterey pine. No analysis was made of the auxins and accessory substances which would necessarily accumulate above the girdle. The effects of defoliation of pines are attributable to stoppage of photosynthesis and reductions in movement in the hydrostatic system by relaxed tensions.

The immediate effects of girdling of *Sequoia* are parallel to those of *Pinus* in the earlier stages, but later 20 to 25 layers of exposed sapwood of *Sequoia* desiccate rapidly and are in a dry and crumbling condition by the end of the season. Subsequently the upward movement of sap is in heartwood through the girdled zone. The scheme of translocation is delineated by which leaf products of an accessory trunk are conducted basipetally in a large root and upward in the xylem and phloem to the lower margin of a girdle. Growth

in trunk and crown took place at a gradually diminishing rate during 21 seasons after girdling a *Sequoia*. Half of the wood below the girdle was burned away at the end of this period, but some green leaves were maintained ~~for a further~~ period of 4 yr., which may be taken as a maximum of endurance. A large *Sequoia* in which fire had destroyed a cone of heartwood in the basal region gave opportunity for observation of the effects of a fortuitous operation complementary to girdling. The outer wood and phloem were in the form of segments of a thin shell. Continuing growth at a reduced rate after 48 yr. was noted. There are 19 references.

**Om kemiske Planteanalyser og deres Anvendelse (On chemical analyses of plants and their use),** F. STEENBERG (*Tidsskr. Planteavl.*, 49 (1944), No. 1, pp. 158-174, illus. 3; *Eng. abs.*, pp. 173-174).—On the basis of pot and field experiments it is shown that the relationship between the percentage of a nutrient in the dry matter of a plant and the amount of it supplied to the soil is expressed by a curve which first falls and then rises as the content of the nutrient in question is increased in the soil. When the experimental results are shown in a system of coordinates in which the ordinates express the amount of dry matter formed and the abscissas give the amount of nutrient absorbed, the result is an S-shaped curve, the point of inflection of which corresponds with the minimum of the curve. Such a curve was observed, however, only when the soil in which the plants grew passed from very deficient to less deficient to rich in the nutrient in question. All the plants were analyzed at maturity except grass, which was analyzed as green hay; the analyses concerned N, P, K, Mn, and Cu. These observations appear to explain several peculiar results encountered in field work, where attempts have been made via plant analyses to show that one soil is richer in a certain plant nutrient than another; thus, by sampling crops in the field, it is often found that the sample representing a crop which would be expected to be most deficient, e. g., in Cu, actually has the highest percentage of this element in its dry matter. It therefore appears necessary to use chemical plant analyses with caution as diagnostic criteria of the deficiency of soils and crops in plant nutrients; this technic should never be used alone, but always in connection with other methods of determination. It is pointed out that experimental evidence tends to show that there are other problems and possibilities which may complicate the problem.

**Effect of alkali upon germinating capacity of seeds of kok-saghyz and of common dandelion.** O. A. PETROVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 49 (1945), No. 3, pp. 227-228).—When seeds of *Taraxacum* spp. were treated with 5 percent solutions of KOH or NaOH the plants developing from treated *T. koksaghyz* seeds were normal, differing in no way from the untreated controls; on the other hand, plants developing from treated seeds of *T. officinale* and *T. serotinum* were abnormal, having underdeveloped root hairs or none and sometimes with dying root tips. These findings suggested the possibility of purifying seeds of kok-saghyz from admixture with seeds of the nonrubber-bearing weed dandelions.

**Translocation of copper ions in plants,** E. M. DELF (*Nature [London]*, 157 (1946), No. 3994, pp. 666-668).—The results of experiments by the author and others suggested that the path and rate of travel of Cu ions are influenced by the specific nature of the plant and degree of differentiation of the tissues, apart from possible differences in the permeability and sensitiveness to Cu ions. Until more is known about such variations it is believed useless to continue comparing rates of travel in the phloem of different plants; the rapidity of the upward movement in *Impatiens* showed, however, that maxi-

imum rates can be obtained only by using very short time intervals after banding; thus the technic and timing of the operations are of first importance. Later the path of translocation in thalli of the brown algae *Fucus* and *Ascophyllum* was studied by use of a mixture of  $\text{CuSO}_4$ ,  $\text{CaCl}_2$ , and soil. The results definitely pointed to an upward translocation of Cu ions (and presumably of other mineral ions) along the broader medullary filaments.

**Studies on foliar hydration in the cotton plant.**—VII, The size factor, T. G. MASON (*Ann. Bot. [London], n. ser., 10 (1946), No. 38, pp. 143-152, illus. 3*).—In this contribution (E. S. R., 94, p. C95), the author examines Richards' criticisms of the size hypothesis (E. S. R., 91, p. 656), pointing out that some of the nutrient solutions employed by Richards and Shih were probably toxic and consequently physiologically arid. Strong indications are presented that the size factor was operating in the plants grown in these solutions. Data are also presented as proof that the reversal in hydration found by Phillis and Mason cannot have been caused by differences in the mineral or carbohydrate levels of the leaves. It is also demonstrated that the size factor may operate when plants are grown under varying N supply. There are 16 references.

**Specificity of potassium and magnesium for growth of *Aspergillus niger*, R. A. STEINBERG. (U. S. D. A.). (*Anter. Jour. Bot., 33 (1946), No. 3, pp. 210-214*).—When *A. niger* was grown in a dibasal solution (optimum yield solution of minimum salt content) for 4 days at 35° C., Na and Be gave increased yields with deficiencies in K and Mg, respectively ("biological substitution"). Increased macronutrients, micronutrients, acidity, or inoculum failed to eliminate the K/Na effect, but did cause increased growth with extreme deficiencies of K and a loss of specificity in the action of Na—i. e., positive effects were also caused by other alkali metals (Li, Rb, Cs). The K optimum (150 mg./l.) remained unaltered in all instances. Responses in the Mg/Be effect to these variations in the dibasal solution were similar (Ca, Sr, Ba), except for its elimination in the presence of increased micronutrients and of acidity. Increased macronutrients or inoculum did not lead to increased yields with extreme deficiencies in Mg. The Mg optimum (10 mg./l.) for maximum growth remained unaltered in all instances. Biological pseudosubstitutions (Li, Rb, Ca, Sr, Ba) were attributed to amelioration of inhibition (ion antagonism).**

**Growth and fruiting of certain ascomycetous fungi as influenced by the nature and concentration of carbohydrate in the medium, L. E. HAWKER and S. D. CHAUDHURI (*Ann. Bot. [London], n. ser., 10 (1946), No. 38, pp. 185-194, illus. 1*).—The effects of a range of concentrations of glucose, fructose, sucrose, maltose, starch, and lactose on the growth and fruiting of seven ascomycetous fungi were studied. Response to glucose or lactose was always of the same type, viz, mycelial growth increased with increase in sugar up to a relatively high concentration, while fruiting reached a maximum at a low concentration—varying with the species—above which it fell off rapidly. Responses to the more complex carbohydrates were of three types: (1) Similar to that of hexose sugars, (2) a starvation type of growth at low concentrations and a slight increase in both growth and fruiting with increased concentration, and (3) an intermediate type where growth and fruiting were poor at low concentrations but increased with increase in amount of carbohydrate until both were good. The type of response of three fungi to sucrose was correlated with the rate at which the sugar was inverted and with the amount of invertase produced per unit dry weight of mycelium. It is suggested that these differences in response can be partly but not entirely ex-**

plained by differences in the rate at which a particular fungus can break down complex carbohydrates to hexose.

**The nature of cellulose in *Sphagnum*,** N. PLANK (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 335-337).—Cross and Bevan cellulose was prepared from *S. recurvum tenuis*; the total amount of cellulose was also determined by a volumetric method. From the crude cellulose,  $\alpha$  cellulose was prepared and the amounts of the  $\beta$  and  $\gamma$  forms were determined by a process outlined. The results indicated peat moss to be lower in the long-chain and pure glucose anhydride cellulose than samples of similarly investigated tissues of seed plants. Results of the cellobiose octaacetate preparation from the  $\alpha$  cellulose obtained indicate that at least 3.8 percent of the carbohydrates present in *Sphagnum* cellulose are definitely glucosans and are linked together by the  $\beta$  1,4 glycosidic linkage.

**The nature and distribution of various forms of nitrogen in the potato,** H. E. STREET, A. E. KENYON, and G. M. WATSON (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 1-12, illus. 7).—As shown by determinations at intervals during active growth, each organ of the King Edward potato plant exhibited a unity in its nitrogenous composition throughout the season. The seed tubers were characterized by their high content of nonprotein N; this fraction yielded the greater part of the N withdrawn from the seed tubers, the amide, amino, and "other N" fractions all being markedly depleted. The severely depleted tubers retained some 20 percent of their initial N content. The roots were rich in nonprotein N, in which the nitrate was an important fraction; the roots from  $(NH_4)_2SO_4$ -treated plots had a higher total N content than those from untreated plots, due to accumulation of  $NH_4$  nitrogen. The "tops" had a higher N content and a higher proportion of protein than the roots. There was an increase in protein and a decrease in nonprotein N in passing from stems to petioles to leaf blades. The depleted tubers, roots, and stems had a uniform low-protein content of the order 0.1 to 0.6 mg. protein N per gram fresh weight. Asparagine and glutamine occurred in approximately equal amounts in the seed tubers and roots; glutamine was more completely withdrawn from the tubers than asparagine, and in the tops it constantly exceeded asparagine in amount. A study of the concentration gradients—from leaves to petioles to stems to stem bases and new tubers—of the fractions of nonprotein N focused attention on the "other N" as containing the organic N most actively involved in translocation. The concentration and total content of the glycoside solanine in the different organs was determined at each sampling.

**Estimation and physiological role of solanine in the potato,** M. J. WOLF and B. M. DUGGAR. (Wis. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 73 (1946), No. 1, pp. 32, illus. 15).—The techniques of extracting potato alkaloids from leaves and sprouts and their separation and purification are described, and some of their properties are discussed. In normal tubers, the highest concentration of solanine occurs in the peripheral zone comprising the periderm and cortical parenchyma; little or none is found in the pith and only small amounts in the intermediate region. From a survey of 32 varieties grown in Wisconsin during one season, the concentration ranged from about 2 to 13 mg. per 100 gm. of fresh tuber, while the tubers of *Solanum commersonii* had as much as 500 mg. per 100 gm. From tests with certain standard potato varieties it was found that in the new plants produced from tubers solanine can be synthesized in darkness, and only a slightly greater solanine production was observed in the light. In the darkness, it was fairly evenly distributed between aerial and subterranean parts; in the light it tended to

concentrate in the tops. Photoperiod affected both the synthesis and distribution of solanine. In a 10-hr. day, its content was 0.059 percent of the total dry weight as against 0.085 percent in an 18-hr. day. In the short day about 58 percent of the glycoside was found in the aerial portion as against 70 percent in the long day.

The percentage concentration of solanine in the tubers declined with advances in the season. In the early variety Irish Cobbler there was an abrupt drop early in the season, after which a low level was maintained. In the late variety White Rural there was an initial rise to a maximum which was maintained for about 2 weeks, followed by a drop. The slowly maturing Russet Burbank showed a steady decline in concentration throughout the season. In all three varieties, the total solanine per hill accumulated with time. Throughout the season, the highest concentration was maintained by the shoot tips. The leaves, exclusive of very young ones at the stem tips, were intermediate in concentration and in all cases showed an over-all drop. The concentration in the older roots was in most cases lower than that in the leaves. Expressed on a dry-weight basis, the solanine content of tubers and of aerial stems was approximately of the same order, and in both it remained relatively low throughout the season in all three varieties. In all varieties, by far the greater part of the solanine per hill was contained in the leaves. The total solanine curves for both leaves and shoot tips showed well-defined maxima; the total in aerial stems and in tubers was very low compared with that in other organs. Tubers are the only organs which showed a continuous accumulation throughout the season, exhibiting a slight but steady rise with time. Aerial stems displayed only minor fluctuations in alkaloid concentration. In all the varieties tested, there was a much greater loss of solanine from the tops than could be accounted for on the basis of transport to underground portions. In White Rural approximately 284 mg. disappeared from the tops, whereas the maximum solanine content of tubers was only about 36 mg. The glycoside is apparently metabolized toward the end of the growing season. Leaves of *S. commersonii* had a solanine concentration of about 2.6 percent on a dry-weight basis and showed no appreciable variation in concentration between July and September.

**The evolution of oxygen from illuminated suspensions of frozen, dried, and homogenized chloroplasts**, C. S. FRENCH, A. S. HOLT, R. D. POWELL, and M. L. ANSON. (Univ. Minn. et al.). (*Science*, 103 (1946), No. 2678, pp. 505-506).—This note summarizes some of the data obtained on the activity of chloroplast preparations treated in various ways. The findings indicate that after freezing, drying, thorough disintegration, or precipitation by ammonium salts, the chloroplasts still retain considerable activity. This study shows further that the ability to produce oxygen is a property not only of intact chloroplasts but also of material exposed to some of the conditions that would be necessary in attempts to fractionate the enzymes involved in the reaction by which  $O_2$  is produced.

**Further studies on plastid variegations**, M. W. WOODS and H. B. DuBUY. (Univ. Md.). (*Amer. Jour. Bot.*, 33 (1946), No. 3, p. 225).—An abstract.

**Aerosol OT in the preparation of microscopic mounts of fungi**, A. J. WHIFFEN (*Mycologia*, 38 (1946), No. 3, p. 346).—The aerosol OT solution has served not only as a wetting agent but also as a mounting medium which is readily miscible with the lactophenol mixture commonly used in preserving temporary mounts.

**Staining the chromosomes of yeast by the Feulgen technique**, M. K. SUBRAMANIAM and B. RANGANATHAN (*Nature [London]*, 157 (1946), No. 3994, p. 657, illus. 9).

**Fibrillar structure of cellulose of bacterial and animal origin, M. ASCHNER and S. HESTRIN** (*Nature [London]*, 157 (1946), No. 3994, p. 659).—That the cell wall of green plants has a fibrillar structure has been demonstrated. Since bacterial cellulose (*Acetobacter xylinum* zooglea) and animal cellulose (tunicin) may be assumed to be formed under conditions differing radically from those involved in cell-wall deposition in plants, it was deemed of interest to study the microscopic structure of these natural cellulose membranes. They also were found to have a fibrillar structure.

**Further consideration of glandular leaf hairs of tobacco and of their significance, F. A. WOLF** (*Bul. Torrey Bot. Club*, 73 (1946) No. 3, pp. 224–234).—The results of further study (E. S. R., 93, p. 697) reveal that hairiness can be increased by hybridization and/or selection. Additional evidence is presented that hairiness is modified in response to spacing practices and to light. These findings indicate that—to a degree—both the volume and quality of aroma are controllable, that all varieties of oriental tobacco may not produce the largest yield and best quality if spaced alike, and that analysis of hairiness seems to provide a means of determining proper spacing and fertilizer practices. There are 14 references.

**Structural composition of the sclereids in the integument of *Pisum sativum* L., R. M. REEVE.** (U. S. D. A.). (*Amer. Jour. Bot.*, 33 (1946), No. 3, pp. 191–204, illus. 19).—Problems of texture constitute a major field of technological investigation in the commercial production of vegetables as food. The causes of texture changes in the seed coats of beans and peas intended for freezing and canning involve biological variables as well as the effects of harvesting, handling, and processing. In the present study, histochemical methods for detecting pentosans in the walls of “hemicellulosic” tissues in seed plants were developed by adaptation of reagents that yield characteristic color products of condensation with pentoses; differentiation between lignin and pentosan reactions was accomplished.

With these methods it became possible to detect the presence of pentosans in the secondary wall thickenings of the macrosclereids and the osteosclereids in the integuments of peas and lima beans. Also, color differentiation between these components and the polyuronides of the middle lamellae was obtained. Arabinose and xylose were tentatively identified as sugars of the pentosan-cellulose complex of the secondary walls; galactose, galacturonic acid, and possibly arabinose apparently occurred as constituents of the middle lamellae pectins. The “light line” of the macrosclereids is considered merely a phenomenon of light refraction, its only significance to composition and textural characteristics of the maturing epidermis lying in the fact that it is caused by the thickened walls. The crystallite orientation paralleled the cellulosic fibrils in both the macrosclereids and the osteosclereids. Observations made on acid-swollen tissues agreed with optical properties as determined with polarized light; there was also agreement with the interpretations of the histochemical tests in relation to wall structure. Further agreement exists between the observations and interpretations recorded here and other published information (37 references) on the chemical composition, optical properties, and structural characteristics of the walls of plant tissues. The relationships of wall structure and texture to problems in commercial food preservation are briefly discussed: The tissue characteristics of texture and permeability are related to the pentosan-cellulose complex of the secondary walls in the macrosclereids; the cuticle may also affect permeability but bears little relationship to texture.

## GENETICS

**Fifty years work as agricultural explorer and plant breeder, N. E. HANSEN.** (S. Dak. State Col.). (*S. Dak. State Hort. Soc., Ann. Rpt., 42 (1945), pp. 119-137*).—The author reviews his work as an agricultural explorer and plant breeder, the occasion being the awarding of a medal to him by the Iowa State Horticultural Society (November 17, 1944).

**Radiation and living cells** (*Nature [London], 157 (1946), No. 3996, pp. 738-739*).—Review of a symposium held at the British Institute of Radiology (May 13-14, 1946) on the general subject "Certain Aspects of the Action of Radiation on Living Cells," and dealing with inactivation of viruses, radiation and dilute aqueous solutions, action of radiation on chromosomes, and radiation and germ cells.

**Chromosome atlas of cultivated plants, C. D. DARLINGTON and E. K. JANAKI AMMAL** (London: George Allen & Unwin, 1945, pp. 397).

**Artificial and natural hybrids in the Gramineae, tribe Hordeae.—I, Elymus, Sitanion, and Agropyron, G. L. STEBBINS, JR., and J. I. and R. M. VALENCIA.** (Univ. Calif.). (*Amer. Jour. Bot., 33 (1946), No. 5, pp. 338-351, illus. 14*).

**Cytology of cereals, II, H. C. AASE.** (Wash. State Col.). (*Bot. Rev., 12 (1946), No. 5, pp. 255-334*).—In this comprehensive supplemental review (599 references) the discussion considers euploid chromosome aberrations; chromosome morphology and genom relationships; aneuploid and structural chromosome aberrations; asynapsis, desynapsis, or dissociation; sterility; polyploidogenic, etc., agencies; embryo sac, embryo, and endosperm; vegetative grafts; and mitotic periodicity. The first decade—freely speaking—of intensive work in the cytology of "small grain" cereals and closely related grasses may be characterized mainly by determination of chromosome numbers in supposedly well-established races and species and by description of general chromosome behavior in a number of varietal, specific, and generic hybrids. The second—or immediately past—decade and the "sundry burden" of this review has become progressively more marked by increased artificial induction of disturbances of the apparently stable state of nature or—perhaps more exactly—by attempts to speed up the slow processes of evolution. "A rugged stability on one hand is yet highly susceptible to change which often manifests itself cytologically as chromosome aberrations, numerical and structural."

**Correlated inheritance of stem rust reaction, nitrogen content of grain, and kernel weight in a barley cross, A. J. LEJEUNE** (*Sci. Agr. 26 (1946), No. 5, pp. 198-211, illus. 6*).—In the variety cross O. A. C. 21  $\times$  Chevron, inheritance of reaction to stem rust is governed by a single factor pair, with resistance dominant. Evidence was found that one or more minor factors modify the reaction of the resistant offspring toward susceptibility; the effect of such modifying factors is, however, of no practical significance. Inheritance of N content in the same cross is governed by multiple factors, with a tendency for the N to be higher in  $F_2$  than in the parents genetically comparable for the stem rust factor. Inheritance of kernel weight is also governed by multiple factors, in this case with a definite tendency toward lower kernel weight in the  $F_2$  than in the parents genetically comparable for the stem rust factor. Few or none of the factors for N content are directly associated or linked with the factor for stem rust reaction; some of these factors, however, are apparently associated with it indirectly through its relation to kernel weight. This indirect relationship results in a weak association of high N content with

\**Bot. Rev., 1 (1935), No. 12, pp. 467-496, illus. 1.*

resistance of stem rust. A large proportion of the factors for 1,000 kernel weight appeared to be linked with the factor for stem rust reaction; this linkage was fairly close and resulted in the association of resistance with low kernel weight, but was broken when a much larger population was employed. In a breeding program to produce stem rust-resistant barley with good malting quality—using Chevron or possibly Peatland as the resistance source—it would be advisable to grow much larger populations than would be needed if no linkage existed between kernel weight and the stem rust factor. There are 13 references.

**Trigeneric hybrids *Elymus* × wheat × rye.** V. E. PISSAREV and N. M. VINOGRADOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 49 (1945), No. 3, pp. 218-219*).—The authors report successful crosses of rye-wheat amphidiploids with *E. arenarius*.

**Inheritance of indeterminate growth in maize.** W. R. SINGLETON. (Conn. [New Haven] Expt. Sta.). (*Jour. Hered., 37 (1946), No. 2, pp. 61-64, illus. 2*).—An indeterminate corn plant, found in the C31 sweet corn inbred, is a simple mendelian recessive *id*. In segregating progenies of *id*/+ plants, the F<sub>2</sub> generation gives 3+ : 1 *id* as is expected. A slight but probably not significant excess of *id* plants occurs. No linkage has been found.

**Photoperiodism and sex in *Zea mays*.** R. S. CHOUDHRI and R. KRISHNAN (*Indian Acad. Sci. Proc., 23 (1946), No. 2, Sect. B, pp. 73-78, illus. 3*).—The effects of 6, 12, 18, and 24 hr. of daily light on sex expression in corn plants grown under low (normal) N and high (additional) N were investigated. The 12-hr. photoperiod plants were characterized by normal ♂ and ♀ flowers; under 6-hr. light periods there was a conspicuous change in the tassels, many spikelets taking on ♀ forms leading to grain formation; under long photoperiods, reversal took place in the ears, where a good many ♂ spikelets developed in place of the ♀ ones. A slight change from staminate to pistillate characters also occurred under the long photoperiods, and is explained on the basis of greater stability of the ♀ over the ♂ characters in corn. Sex modifications were also initiated by heavy N nutrition, which accelerated the change from ♂ to ♀ in the tassels but caused a relative inhibition of sex reversal in the ear.

**Secondary association and heterochromatic attraction.**—I, *Cicer arietinum*, P. T. THOMAS and S. H. REVELL (*Ann. Bot. [London], n. ser., 10 (1946), No. 38, pp. 159-164, illus. 11*).—No difference in the chromosome number of a "normal" and a gigas type of gram chickpea (*C. arietinum*)—reputed to have 14 and 16 respectively—could be observed; though genetically distinct, both had 16 chromosomes. The chromosome complements of both were morphologically similar, but an extra fragment was seen at meiosis in some plants of the normal type. The haploid chromosome complement consists of 2 large chromosomes—distinguishable from each other, 5 medium, and 1 small chromosome. The detailed results of the study are presented. In the diploid, analysis of secondary association need not indicate chromosome relationship whereas in the tetraploid it may do so, depending on (1) the degree of prezygotene orientation and (2) the amount and distribution of heterochromatin.

**Albinos in pinto beans.** G. N. STROMAN. (N. Mex. Expt. Sta.). (*Jour. Hered., 37 (1946), No. 2, pp. 59-60*).—Albinos appearing in pinto beans apparently were caused by a recessive gene, with a possibility of modifying factors.

**Karyotype evolution: A cytogenetic study of seven species and six interspecific hybrids of *Crepis*.** M. SHERMAN (*Calif. Univ. Pubs. Bot., 18 (1946), No. 17, pp. 369-407 +, illus. 37*).

**Tetraploid *Taraxacum kok-saghyz*.—II, Characters of  $F_1$  plants grown in pots.** M. W. BANNAN (*Canad. Jour. Res.*, 24 (1946), No. 3, Sect. C, pp. 81–97).—In the present study (E. S. R., 94, p. 43),  $F_1$  tetraploids grown in pots had larger but fewer leaves and inflorescences than control diploids. Increase in size of organs was offset by reduction in numbers, so that leaf area was no greater and the total number of florets per plant was much lower in the tetraploids. Fertility varied inversely with genetic relationship and was much reduced in the tetraploids. No significant differences in root size were noted. The tetraploids grew somewhat more slowly than the diploids but for a longer time, and, on the whole, plants with the largest rosettes developed the largest roots also. Sibling tetraploids exhibited less deviation from the mean than randomized plants in such characters as number, size, and shape of leaves, production of heads, and weight of roots. Leaf characters provided the clearest evidence of an inheritance mechanism; the data on root weight were less conclusive.

**A cytological basis of sterility in *Tripsacum laxum*,** K. S. DONNS and N. W. SIMMONDS (*Ann. Bot. [London]*, n. ser., 10 (1946), No. 78, pp. 109–116, illus. 11).—The chromosome number of *T. laxum* (Guatemala gamagrass) was confirmed as  $2n = 72$ . Most chromosomes were associated as bivalents, but there were irregularities of association, congression, and separation resulting finally in  $\delta$  sterility. Bridges were not seen at first anaphase; their occasional occurrence at second anaphase is interpreted as a consequence of chromatid fusion.

**On heterosis effects in *Triticum vulgare*,** I. GRANHALL (*Hereditas*, 32 (1946), No. 2, pp. 287–293).—In two wheat crosses the author found the heterozygous half-bearded  $F_2$  plants averaging more vigorous than corresponding beardless and bearded groups. In the first case, two very different spring wheats—Hindi and Extra-Kolben II—were crossed; in the other, a winter wheat—Pansar—and its bearded mutant were used as parents. The findings provide strong indications of pleiotropic effects of the beardless factor or absolute linkage between this morphological factor and quantitative physiological genes. The second cross—where the parents differed only monofactorily—gives a clear demonstration of real heterosis stimulation. In the cross of two very different varieties, the average number of culms of the  $F_2$  plants failed to reach the mean of the two parents; in the other cross—where the parents differed in only a single factor (or factor complex)—the corresponding differences in vitality were numerically very small and quite insignificant, in accordance with expectations. As to plant height, the average of  $F_1$  from the first cross was higher than the mean of the two parents. This is explained by assuming that one of the parents (Extra-Kolben II) includes some strongly dominant length factors, whereas the other parent (Hindi) has the recessive alleles.

**The effect of heterozygosity on variability and vigour,** A. GUSTAFSSON (*Hereditas*, 32 (1946), No. 2, pp. 263–286).—The author reviews previous results along this line in plants and animals (22 references) and presents some further cases of monohybrid heterosis in barley. The series of data given are believed to show that mutations lethal in the homozygous condition may increase viability when they occur in the single dose. Vigor may also be affected in a general sense: In some plants the reproductive capacity is increased along with properties such as length of culm or head and ability to tiller. Heterozygous seeds of the barley mutation *albina* 7 kept their germinating capacity longer than the homozygous seeds; this was especially conspicuous in medium strong and strong plants. A tendency existed to

increase the range of variation in mono- and di-hybrids as compared with the homozygous sister plants. Some of the problems on population dynamics and inbreeding degeneration are discussed briefly.

**The genesis of some Scandinavian species of *Calamagrostis*, A. NYGREN** (*Hereditas*, 32 (1946), No. 2, pp. 131-262, illus. 235).—A comprehensive report covering results of cytological studies of *Calamagrostis* spp., analytical studies of populations of both amphimictic and apomictic species, isolation and crossing experiments, analysis of pollen and pollen germinability, and cytological studies of F<sub>1</sub> hybrids between different amphimictic *Calamagrostis* spp. Literature cited includes 158 references.

**Maintenance of heterozygosity in a homothallic [fungus] species of the *Neurospora tetrasperma* type, E. R. SANSOME** (*Nature* [London], 157 (1946), No. 3989, pp. 484-485, illus. 2).

**Reverse-mutation and adaptation in leucineless *Neurospora*, F. J. RYAN and J. LEDERBERG** (*Natl. Acad. Sci. Proc.*, 32 (1946), No. 6, pp. 163-173, illus. 3).—On the basis of the evidence presented, it is concluded that the reverse mutation to the wild-type allele does occur. The leucineless mutant of *N. crassa* is a true mutation. The adaptation to leucine independence which this mutation sometimes undergoes is due to back mutation to the wild-type condition at the leucineless locus. This was demonstrated by the genetic behavior of the adapted strain in crosses with leucineless and by the genetic behavior of the leucine-independent F<sub>1</sub> progeny in crosses with the wild type. Moreover, the adapted and wild-type strains proved to be physiologically identical. The incidence of adaptations was significantly higher in the presence of low than of high concentrations of leucine. This apparent chemical induction of mutations has its explanation in the fact that a back mutation in the leucineless strain always resulted in the formation of a heterocaryon. In a heterocaryon between the leucineless and the adapted or wild-type strains, the leucineless nuclei have an advantage in the presence of leucine. Whether a back mutation will result in an adaptation depends on whether conditions favor selection against the leucine-independent nuclei.

**Inherited differences in sensitivity to radiation in *Escherichia coli*, E. M. WITKIN** (*Natl. Acad. Sci. Proc.*, 32 (1946), No. 3, pp. 59-68, illus. 2).—A strain of *E. coli* yielded variants characterized by resistance to both ultraviolet and X-ray irradiation and detected by the selective action of these radiations; this resistance proved to be a stable heritable property. A technic is described by which the number of resistant bacteria in samples from normal cultures can be accurately determined. The change from sensitivity to resistance is said to be a spontaneous mutation in normal cultures at a rate of about  $1 \times 10^{-5}$  mutations per bacterium per generation. Ultraviolet doses that inhibit cell division for several hours in sensitive bacteria—resulting in the production of elongated cells—did not appreciably inhibit division in resistant bacteria. Curves of survival in sensitive and resistant bacteria as a function of ultraviolet and X-ray doses are compared. Certain features of these findings are discussed.

**Genetical factors concerned in the symbiosis of clover and nodule bacteria, P. S. NUTMAN** (*Nature* [London], 157 (1946), No. 3989, pp. 463-465).—A brief review (6 references) and account of preliminary experimental results suggesting that "resistance" is inherited as a recessive in conjunction with a possibly cytoplasmic maternally transmitted component. The general conclusion is that the number and activity of nodules formed on the plant depend on the interaction of factors—in bacteria and plants—both liable to change by mutation. It was also evident that critical studies of symbiosis demand the

use of clonal lines of bacteria, as well as a much fuller knowledge than now available on the inheritance and activity of the coordinating factors in the plant. The relationship between the two organisms would seem to be much more complex than is generally supposed. On the practical side it is shown that with a strain of bacteria normally giving a response intermediate in effectivity toward plant material of mixed genetical constitution, selection to increase the effectivity of response is possible; thus far selection for responsiveness to native totally ineffective strains of bacteria has been unsuccessful, so that the problem of these strains must apparently be dealt with from the bacteriological side.

**Animal breeding**, A. L. HAGEDOORN (London: Crosby Lockwood & Son, 1946, 2. ed., pp. 304, illus. 29).—This edition (E. S. R., 82, p. 754) adds "a few things, especially some examples taken from the results of my own experimental work during the war years."

**Genetics of the Palomino horse**, W. E. CASTLE. (Univ. Calif.). (*Jour. Hered.*, 37 (1946), No. 2, pp. 35-38, illus. 4).—Data are presented which the author interprets as confirming the Salisbury-Britton hypothesis as to the Palomino coat color (E. S. R., 86, p. 313).

**Cross-breeding with dairy cattle**, M. H. FOHRMAN. (U. S. D. A.). (*Amer. Milk Rev.*, 8 (1946), No. 6, pp. 34, 36-38, illus. 4).—A preliminary report is given on production records obtained in an experiment in cross-breeding begun in 1939 and including Holsteins, Jerseys, Guernseys, and Red Danes. A summary of the records completed by 32 two-breed and 5 three-breed cows showed an average of 13,095 lb. of milk and 599 lb. of milk fat at the average age of 2 yr. 2 mo. A discussion of the possibilities for expanding the usefulness of registered cattle through the commercial application of cross-breeding of dairy cattle is included.

**The colostrum pregnancy test in cattle**, C. F. CAIRY. (Mich. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 6 (1945), No. 21, pp. 252-256, illus. 1; *abs. in Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 360-361).—The results are presented of 322 colostrum injections with 35 cows and of 17 with 2 freemartins. The "colostrum" used was not the postpartum or true colostrum, but the material which accumulates in the udder before parturition in first-calf heifers. Several samples were used in various amounts and different dilutions.

Analysis from the standpoints of the response of individual cows, the antigen used, the amount injected, and the dilution used indicated that while there appeared to be marked differences in the responses of some animals to certain antigens, the test is not of sufficient accuracy in the bovine to be used as a pregnancy test. It seemed that the variations in responses to the test were due not so much to the differences between antigens, dilutions, and the amounts injected as to differences between the individual cows. However, certain individual cows responded with an accuracy of better than 90 per cent.

**Mitotic activity in the adult female mouse *Mus musculus* L.: A study of its relation to the oestrous cycle in normal and abnormal conditions**, W. S. BULLOUGH (*Roy. Soc. London, Phil. Trans., Ser. B*, 231 (1946), No. 585, pp. 453-516+, illus. 38).—A survey has been made of the mitotic activity of the reproductive system, the urinary system, the alimentary canal, various exocrine and endocrine glands, and other miscellaneous organs of nearly 500 adult female mice, both in relation to the normal estrus cycle and to injections of estrone. A similar survey has also been made of the mitotic activity associated with wound healing and with cancerous growth.

It is concluded that in the adult female mouse, and probably in other animals, there exist three types of substances influencing mitotic activity. First, there are the estrogenic hormones which act as general mitosis stimulators; second, there are the mitosis-inhibiting forces of cell inertia and mitosis depression, which prevent the rate of cell division from becoming excessive and unregulated; and third, there are the wound hormones which, by weakening the mitosis-inhibiting forces, allow an abnormally high reaction to estrogen stimulation and a consequent rapid production of new tissue to meet the emergency. This conclusion is discussed in relation to several biological problems, including ovarian function, pregnancy, embryonic growth, and cancer.

**The inbred hybrid, J. H. MARTIN.** (Purdue Univ.). (*Hatchery Tribune and Feed Retailer*, 20 (1946), No. 7, pp. 21, 60-64, illus. 1).—This is a brief review of experimental work with inbreeding and hybridization in poultry. It is stated that "the answer to the future of the hybrid chick rests in the hands of the poultry breeders who are willing to take the hazards involved in an inbreeding program."

**Production of strophosomy in the chick embryo by local applications of colchicine, M. L. GABRIEL.** ([Conn.] Storrs Expt. Sta.). (*Jour. Expt. Zool.*, 101 (1946), No. 3, pp. 351-354, illus. 4).—The embryonic area of chick embryos of 25-28 somites was explored by treatment with narrow bands of colchicized agar. The results obtained indicated that the region between the omphalomesenteric vessels and the hind limb buds is most susceptible to the induction of strophosomy.

**The effect of local applications of colchicine on Leghorn and polydactylous chick embryos, M. L. GABRIEL.** ([Conn.] Storrs Expt. Sta.). (*Jour. Expt. Zool.*, 101 (1946), No. 3, pp. 339-350, illus. 4).—A method has been described for treating localized regions of the chick blastoderm with colchicine soaked up on neutral-red stained agar films. Colchicine, in concentrations of 0.0001-0.0005 gm./cm.<sup>2</sup> thus applied, produces local defects pointing to high determination of the hind limb at the 25-somite stage, strophosomic embryos, and dwarfed limbs. The significance of the experimental production of defects and dwarf limbs for the problem of polydactylism is discussed. The hypothesis is advanced that polydactylism is not the result of added halluces, but is the partially inhibited expression of a duplicated limb field.

**The effects of hypothermia upon the reproductive tract of the hen, P. D. STURKIE.** (N. J. Expt. Stas.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 369-372).—Hypothermia was induced in over 100 White Leghorn females, at varying intervals up to 9 hr. after laying, by submerging the birds up to the neck in water of the appropriate temperature. The subnormal-body temperature, which varied from 83° to 102° F., was maintained for 1 to 14 hr. When the treatments were terminated the birds were removed from the cold bath, placed in warm water, and then dried in a forced-draught incubator at a temperature of 99.5°. In most cases, those hens which had eggs in the uterus when the body temperature was subnormal laid their eggs prematurely (soft-shelled), whereas most of the hens which had regained normal body temperature before the egg entered the uterus laid hard-shelled eggs. The time of laying of the hard-shelled eggs was delayed. The hypothermia did not hinder ovulation, and it probably had little, if any, effect upon the rate of passage of ova to the uterus.

**Hatchability in relation to consanguinity of breeding stock in turkeys, M. A. JULL and R. E. PHILLIPS.** (Md. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 312-319).—Results are tabulated of the infertility and hatchability

percentages obtained with outbred Black hens and heterozygous Black hens mated to outbred Black toms, Beltsville Small-Type White hens mated to Beltsville Small-Type White toms or an outbred Black tom, outbred Black Hens and heterozygous Black hens mated to a heterozygous (three-fourths) Black tom, and Beltsville Small-Type White hens mated to a Beltsville Small-Type White tom (their sire the previous year) or to an outbred Black tom.

The results secured from these various matings indicate that "hatchability among female progenies is influenced more by the heritable hatchability of parents than by the particular kind of mating. For the most part, outbred, mildly inbred, and crossbred matings gave comparable results with respect to percent hatchability of fertile eggs. Inbreeding, involving matings of brother  $\times$  sister, son  $\times$  dam, and sire  $\times$  daughter, produced satisfactory results when parents were selected on basis of heritable hatchability. The importance of selecting breeding stock on the basis of the dam's family average hatchability is clearly demonstrated."

**The environmental conditions affecting the genetic mechanism of wing production in the chrysanthemum aphid.** W. S. WHITE (*Amer. Nat.*, 80 (1946), No. 790, pp. 245-270).—Approximately 29,000 chrysanthemum aphids (*Macrosiphum sanborni*) were reared under controlled conditions to study the effect of light, temperature, wilting of the host plant, presence or absence of wings in the parents, and environment of the stock on wing production. Every one of the factors tested had a noticeable influence, but "weighting of their effects would assign the greatest influence to the light conditions prevailing during the experiment. Second place would be given to the temperature used during the experiment. The environment of the stock from which the experimental animals were drawn is third in importance, followed by the presence or absence of wings in the parent aphids. The least effective of all the agents tested was the condition of the host plant, whether wilted or fresh."

## FIELD CROPS

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, pp. 1, 5, 8).—Articles reporting results of experiments with farm crops are entitled: Effect of Crop Rotation on Cotton Yield Tested at State College and Holly Springs, by R. Coleman and S. P. Crockett (pp. 1, 5); and Time of Applying Nitrogen Materials in Delta Oats Test, by J. Pitner (p. 8).

**Grasses and cultural methods for reseeding abandoned farm lands in southern Idaho.** R. H. STARK, J. L. TOEVS, and A. L. HAFENRICHTER. (Coop. U. S. D. A.). (*Idaho Sta. Bul.* 267 (1946), pp. 36, illus. 10).—Grasses and grass mixtures, methods of preparing seedbeds, and methods and dates of seeding were compared 1939-44 on typical eroded abandoned land in southern Idaho. Relative costs and returns were computed. Summer-fallowing, found the best method of preparing abandoned land for seeding, reduced competition from annual cheatgrass and weeds, eliminated sagebrush, rabbitbrush, and poisonous plants, and made possible good, uniform stands of perennial grasses from spring seeding as well as from fall planting. Seedings on summer fallow developed to full production one and two years earlier than those on other seedbeds. Various types of grasses were established successfully on summer-fallowed abandoned land. Several kinds of drills were used with equal success. Other methods of seedbed preparation resulted in satisfactory stands of crested wheatgrass and bluebunch wheatgrass from fall plantings. Duckfooting just prior to seeding resulted in good establishment, but stands

were retarded in reaching full production. Where cheatgrass containing some sagebrush and rabbitbrush was burned to prepare land, good stands were obtained from fall seedings. Stands of perennial grasses seeded in cheatgrass without seedbed preparation were erratic.

Acre costs of preparing seedbeds by summer fallowing have averaged \$1.10, duckfoot cultivating \$0.30, and burning \$0.19. Drilling has averaged \$0.35 per acre; taxes and interest vary with the locality, and cost for seed varies with the kind and amount used and market fluctuations. Return from summer fallowing would easily offset the additional cost for a method of seedbed preparation that assured stands and provided one or two more years of full grazing use.

The beet drill produced the most uniform stands, but single-disk, double-disk, and deep-furrow drills were entirely satisfactory. When seeding directly into cheatgrass without seedbed preparation, deep-furrow drills gave the better results, and stands were more uniform. There were no significant differences in yield due to type of drill, and none attributable to differences in depth of seeding within the limits from  $\frac{1}{2}$  in. on land with no preparation to  $2\frac{1}{2}$  in. on seedbeds prepared by duckfooting. The beet drill gave positive uniform depth control, and uniformity of stands was exceptionally good. Uniform seeding depth was accomplished with other drills by a moderate and uniform rate of speed when seeding. Shallow rod-weeding of summer fallow just before planting facilitated depth control and provided uniform seeding conditions. Fall and early spring seedings of crested wheatgrass, and usually of bluebunch wheatgrass, did not differ much in yield.

Native and exotic wheatgrasses and native bluegrasses were best adapted. Improved strains of native bluebunch wheatgrass and introduced tall wheatgrass gave about the same grazing capacity per acre as crested wheatgrass when stands reached full production. The 3 bunch wheatgrasses have different seasons of use. Tall wheatgrass was the latest of all, and extended the grazing season as much as 30 days into the rainless summer months after the other grasses were dry and fibrous. Bluebunch wheatgrass was 2 weeks later than crested wheatgrass. The season for use for western wheatgrass corresponded to that of bluebunch wheatgrass, and that for thickspike wheatgrass to crested wheatgrass. By seeding separate pastures to grasses with different season of use, the grazing season was extended by 4 to 6 weeks. Crested wheatgrass reached full production on summer fallows by the end of the third growing season, bluebunch wheatgrass in the fourth season, and tall wheatgrass in the fifth season.

Selected strains of native western wheatgrass and thickspike wheatgrass did not differ in grazing capacity for seedings of the same age. Each required 1 yr. more than did crested wheatgrass to reach full production. When these sod-forming grasses were fully developed, the grazing capacity did not differ from that of bunch-type wheatgrasses. "Streambank" wheatgrass, a dwarf form of thickspike wheatgrass, adapted to rigors of soil and climate but low in grazing capacity, was easy to establish and reached full production as soon as crested wheatgrass.

Mixtures had no advantage in production over pure stands. In mixed alternate-row seedings of perennial grasses, sod-forming grasses tended to spread to an optimum density where bunchgrasses were thin. If sod and bunchgrasses are seeded together, those having similar season-of-use should be combined; crested wheatgrass should be planted with thickspike wheatgrass and bluebunch wheatgrass with western wheatgrass. Streambank wheatgrass can be used with either bunchgrass to provide understory ground cover. A

good combination of grasses was the alternate-row seeding of Michel rye with the wheatgrasses, with the rye harvested for hay the year after seeding.

Seedbed preparation by fallowing, cultivating, or burning reduced cheatgrass prevailing on the area, which made conditions favorable for establishment of perennial grasses. Good, uniform, and mature stands of adapted perennial grasses had basal densities averaging 2.67 percent and varying from 2.0 percent to about 4.0 percent, and the average acre production was 1,173 lb. Cheatgrass stands having basal densities between 2.0 and 4.0 percent, averaging 2.64 percent, made an average of only 607 lb. This emphasizes the relative merits of these grasses and shows the importance of good stands of perennial grasses to production and grazing capacity.

**Two new grasses, Mandan wildrye and green stipagrass, G. A. ROGLER.** (Coop. U. S. D. A.). (*North Dakota Sta. Bimo Bul.*, 8 (19'6), No. 5, pp. 11-12).—Mandan wild-rye, selected from Canada wild-rye (*Elymus canadensis*), is characterized by ease of establishment, rapid growth, high yields of seed and forage, value in mixture with other grasses, wide adaptation, especially on sandy soils, endurance of grazing, and superior resistance to rust. The plants are finer, shorter, and leafier than in ordinary Canada wild-rye, and are longer lived than many strains.

Green stipagrass, an improved variety of feather bunchgrass (*Stipa viridula*), also selected at Mandan, surpasses ordinary feather bunchgrass in vigor, size, and forage yields, and seed yields are satisfactory. This variety, one of the highest yielding of the cool-season grasses tested at Mandan, makes very rapid growth after defoliation and is especially useful for pasture seedings. It grows well with other grasses and should be seeded in mixtures for general farm use. It thrives on most soil types and probably can be grown successfully over most of the northern Great Plains.

**Classification of barley varieties grown in the United States and Canada in 1945, E. ÅBERG and G. A. WIEBE.** (Coop. Univ. Wis.). (*U. S. Dept. Agr., Tech. Bul.* 907 (1946), pp. 190, illus. 93).—Commercial varieties of barley grown in the United States and Canada and those used extensively in breeding and of special interest, a total of 90 spring and 50 winter varieties, are classified and described, and many are illustrated with notes on history and distribution. Species of barley (*Hordeum* spp.) are discussed. The main ecological barley groups grown in these countries are discussed from the viewpoints of origin, distribution, characteristics, and breeding. The botany of the barley plant and the characters found in each plant part are described and illustrated with discussion of each character's stability under different environmental conditions and its value for use in classification. Determinative keys include one for all spring varieties, another for all winter varieties, two regional keys for grown spring barleys covering the two major ecological groups, and a key for identifications from threshed grain of important commercial spring barleys.

**Bay, a new barley variety, J. W. THAYER and E. E. DOWN** (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 270-271).—Bay, a new variety selected from Minnesota 450 × Spartan barleys and released in 1945, has stiff straw, erect 6-rowed heads, and smooth awns, makes good yields, and is as acceptable for malting purposes as Wisconsin Barbless (Wisconsin 38), and possibly superior in certain respects.

**Birdsfoot trefoil (*Lotus corniculatus* L.), its characteristics and potentialities as a forage legume, H. A. MACDONALD** ([*New York*] *Cornell Sta. Mem.* 261 (1946), pp. 182, illus. 48).—Characteristics of birdsfoot trefoil and its development from seed germination to maturity are discussed, and attention

is given to its history, distribution, and world adaptation. Experiments 1938-43 dealing with the growth and habit of the plant, its soil fertility and ecological requirements, culture, seeding, and management, its production for hay, pasture, and seed, and its other uses and limitations, are reported together with results of a survey covering the plant's indigenous occurrence in New York. The bibliography comprises 342 references.

Birdsfoot trefoil, a long-lived perennial, was slow to establish, and may be injured severely by unfavorable conditions in the seeding year. When well established it was found adapted to a wide range of soil types and soil-moisture conditions. The narrow-leaved variety (*tenuifolius*) was better suited to moist situations than was the broad-leaved type (*vulgaris*). For N fixation, birdsfoot trefoil required a symbiotic *Rhizobium* species different from other common legumes. Response to fertilizer resembled that of other agricultural legumes, although birdsfoot trefoil persisted and produced at lower soil fertility levels than did other forage legumes. Its soil-lime requirement was less than that for alfalfa. Differences in response to various soil factors of the legumes tested were apparently correlated with variations in type of root system. The deep root system of birdsfoot trefoil, together with its profuse branching in the upper soil zone, appeared to give it a distinct advantage over a wide range of conditions. After establishment, it was more drought-resistant than were such shallow-rooted legumes as white clover.

Spring seeding of birdsfoot trefoil in the vicinity of Ithaca, N. Y., was superior to fall seeding, and seedings to a depth of from 0.25 to 0.5 in. gave results superior to those from shallower or deeper seedings. No improvement in yield came from seeding more than 5 lb. per acre. Where there were good soil preparation and favorable growing conditions, use of a cereal companion seeding retarded seedling establishment of birdsfoot trefoil. When used, a lower than normal rate of seeding of the companion crop was desirable.

Birdsfoot trefoil, normally lower-yielding for hay than alfalfa on soils adapted to alfalfa, was the better on soils unsuited to alfalfa. Red clover normally outyielded it in the first harvest year, but did not persist thereafter in appreciable quantity, as did the trefoil. The stem of birdsfoot trefoil was found to be weak, and its seeding with a strong supporting grass to prevent lodging was found desirable. Plants offering excessive competition in mixtures with birdsfoot trefoil were distinctly detrimental to its maximum production.

For pasture, birdsfoot trefoil gave best results when seeded with an open sod-producing grass, notably with Kentucky bluegrass, timothy, or orchard grass. It compared favorably with wild white clover and maintained fall greenness for several weeks after the other legumes had been severely injured and defoliated by frost. Birdsfoot trefoil was about as palatable as other legumes of similar nature and stage of maturity. Insofar as N, Ca, P, and lignin are concerned, this trefoil is equivalent in nutritive value to alfalfa for hay and white clover for pasture. Its cyanophoric properties varied, but no harmful effect was produced nor HCN poisoning found where stock fed upon it.

Production of seed of birdsfoot trefoil presented a major problem, retarding its use as an agricultural crop, for the mature pod shattered readily, necessitating great care in handling to prevent undue seed loss. Few insects or diseases were found to seriously affect the plant. A number of superior strains of this legume were selected.

Birdsfoot trefoil, while little used in American agriculture, appears to show enough desirable characteristics to warrant further investigation and im-

provement. The crop evidently cannot be expected to compete with alfalfa or red clover for hay production on the better soils and under a short-rotation system of farming, but it has distinct possibilities for hay and pasture on secondary, or poorer, soils where alfalfa does not succeed, where red clover is too short-lived for the rotation used, and summer conditions too droughty for persistence of white clover.

**Birdsfoot trefoil may propagate by root cuttings**, A. R. MIDGLEY and A. GERSHOY. (Vt. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 197-199, illus. 3).—When plants of *Lotus corniculatus* were removed from the field and the tapering tap roots cut into segments 2 to 6 in. long, these crownless roots produced many new plants when planted. Rapid shoot proliferation from severed roots suggested that heaving on clay soils as well as occasional disking should thicken up established stands of birdsfoot trefoil.

**The development of buffalo grass seed**, J. R. HARLAN. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 135-141, illus. 2).—Details of the development of the seed of buffalo grass (*Buchloe dactyloides*) from the unfertilized ovary to maturity are described. The striking feature is the green scutellum which forms a broad shield behind the remainder of the embryo and on maturity covers the entire dorsal surface of the endosperm. A similar scutellum development is reported for the genus *Bouteloua*.

**The relation of corn yields to nutrient balance as revealed by leaf analysis**, E. H. TYNER and J. R. WEBB. (W. Va. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 173-185).—An investigation with corn grown under field conditions dealt with N, P, and K interactions and balances occurring within the leaf tissue and their significance in determining efficiency of utilization of applied fertilizers as reflected by grain and stover yields. N and K exerted reciprocal influences. N fertilizers markedly depressed the percentage of K found in the leaves. At high rates of N application, the depression was large enough to induce an incipient K deficiency, which was reflected by a reduction in efficiency of N utilization. K had a slight depressive effect on the percentage of N, but this did not appear to affect yields significantly. P had no effect on either N or K contents; nor did N or K appear to affect P content. A suggestion was that NK balances might assume critical importance under field conditions on soils of low to moderate K or N supplying power.

**Maize in Mexico.—A preliminary survey**, E. ANDERSON (*Ann. Missouri. Bot. Gard.*, 38 (1946), No. 2, pp. 147-247, about 100 illus.).—Mexican corn, as described, varies from plant to plant in the same field and among fields in the same locality, as in the United States. These variations are greater in magnitude, and the regional variation is beyond anything encountered in the United States. The customary groupings of dent corns, popcorns, flint corns, etc., are considered to be misleading in Mexico. A method of measuring and describing corn populations (fields) developed is applied to the Mexican collections in analysis of the association and geographical distribution of high row number with narrow, pointed kernels. Other characters are shown to be associated with these trends in row number and shape of kernels. High row number, pointed kernels, wide, hairy leaves, condensed tassels, constitute a complex characterizing the Mexican Pyramidal race, centered in the State of Mexico. Low row number, long, irregularly tapering ears, wide kernels, narrow leaves, long, wiry tassel branches, form a complex characterizing the Mexican Narrow Ear race of western Mexico. A third race, Mountain Yellow, which resembles Guatemalan corn, is restricted to high altitudes, and from Jalisco eastward to Toluca becomes increasingly mixed with Mexican

Pyramidal. Corns grown for special purposes include varieties with colored aleurone, used as green corn, which apparently spread from western Mexico in ancient times and have become more or less mixed with the common varieties of each region; a large-kernelled flour corn known as "Cacahuazintle" apparently derived from the "Salpor" variety of Guatemala; maize dulce, whose significance in the history of American sweet corns is briefly indicated; the ancient popcorn of the west coast, maize reventador (E. S. R., 92, p. 503), and the different rice popcorns of the State of Mexico. Classification of the corn of Mexico, origin of denting in corn, and the genetics of multiple factor characters in North American corn are discussed in the light of the above survey.

**Hybrid popcorn in Indiana**, G. M. SMITH and A. M. BRUNSON. (Coop. U. S. D. A.). (*Indiana Sta. Bul.* 510 (1946), pp. 16+, illus. 9).—Cooperative breeding work (E. S. R., 93, p. 429) resulting in superior hybrid popcorns, performance trials, and popping expansion determinations are reported on, and recommendations are made on culture, storage, handling, and marketing the crop. The extent of the industry in Indiana is shown by counties. The several kernel types of Purdue popcorn hybrids and the parental inbreds are described.

Hybrids described have yielded from 9 to 72 percent more than the open-pollinated varieties with which they were compared, and were also superior in popping expansion and standing ability. Use of second generation hybrid seed is not recommended because of serious reductions in yield and uniformity. In general, the culture of popcorn is identical with that of dent corn. Pollination by dent corn or sweet corn does not materially affect the popping quality of that year's crop. Popcorn must mature on the plant completely and normally to be of good quality. Natural curing in narrow, well-ventilated cribs is deemed best. Where artificial drying is necessary, drying temperatures should be relatively low. Popcorn should not be shelled until it has dried to about 13.5 percent moisture content, optimum for best popping.

**Fruiting and shedding of cotton in relation to light and other limiting factors**, A. A. DUNLAP (*Texas Sta. Bul.* 677 (1945), pp. 104, illus. 23).—Research on effects of light, especially periods of low light intensity, together with related studies on other factors, as variations in water supply, high temperatures, N-P-K ratios, and varietal differences among upland cottons in sensitiveness to unfavorable light conditions, all in relation to fruiting and shedding in cotton, was conducted at the station 1939-45.

Cotton plants become well-fruited under conditions favoring production of a large number of blooms, little shedding, and moderate vegetative growth. Adequate sunlight is an important factor in these conditions, according to these studies. Variations in amount of light, such as accompany periods of cloudy weather, short days, and close spacing of plants, were found to result in impairment of fruiting and excessive vegetative growth. Heavy shedding of young bolls, often noted by growers after periods of rainy weather, appears probably due to the interruption in high sunlight intensity rather than to direct effects of rain on the flower. Modified light conditions and other factors that induce shedding were found to hinder photosynthesis and to reduce the carbohydrate content in cotton leaves. Differences in the sensitiveness of cotton varieties to unfavorable light conditions indicated the importance of careful selection of varieties for a given region, according to prevailing weather conditions during the fruiting season, and the need for attention to these inherent varietal differences by cotton breeders. Varieties

as Stoneville 2B, Coker 4-in-1, Deltapine 14, Half-and-Half, Roldo Rowden, and Washington, were found, in general, to be less sensitive to unfavorable variations in light conditions than such varieties as Qualla, A. D. Mebane Estate, Rogers Acala, and Lone Star.

**Preliminary information on sweet lupines in the United States,** R. MCKEE, H. L. HYLAND, and G. E. RITCHEY. (U. S. D. A., Fla. Expt. Sta., and La. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 168-172).—Good growth and yields have been attained by nonalkaloid selections of yellow and blue species, but rather low yields by the white species, included in experimental plantings in the United States. Determination that varieties cross within species has made it necessary to keep isolated nonalkaloid selections from high-alkaloid plantings. Possible value of nonalkaloid lupines for livestock feed is suggested, and experiments to determine their feeding value are in progress at the Florida Experiment Station. A quick method for determining the presence of alkaloid is outlined.

**Oat variety studies in Tennessee,** N. I. HANCOCK and O. H. LONG (*Tennessee Sta. Bul.* 199 (1946), pp. 29, illus. 8).—Fall-sown oats are of considerably more value than spring-sown oats in Tennessee; selected winter-hardy varieties averaged 31 bu. per acre more than the best spring varieties. The fall-planted crop matures from 7 to 10 days earlier than spring-sown oats, and, as a rule, before rust infection damages seriously. Fall-sown oats also retard erosion during winter months when rainfall is heavy, and, when seeded early, provide very palatable winter pasture. Tennex, Fulwin, and Forkeddeer, derived in Tennessee from Fulghum oats, are winter hardy and in all trials outyielded Winter Turf, once the standard variety. They are often sown after corn with satisfactory results. Lee, Letoria, Stanton, and Fulgrain belong in the semi-winter-hardy group, which do not retain dormant, prostrate seedling growth under variable climatic conditions. In Tennessee, such varieties are adapted only to restricted dates of seeding in the fall. Semi-winter-hardy varieties thus far introduced are not vigorous growers and are better adapted to high levels of fertility than to low levels. Of this group, Fulgrain stands up best. Since low levels of fertility of oats land predominate in Tennessee, vigorous oats such as Tennex, Fulwin, and Forkeddeer are required. On medium to high levels of fertility, these 3 varieties have wide spread of seeding dates, Forkeddeer standing up best. All three Tennessee varieties mature earlier than Winter Turf and Lee. Fulgrain and the Tennessee selection of 090 × Bond 140-17-63-75 are the earliest maturing of all oat varieties tested so far, but sometimes they are damaged by late spring freezes. For spring sowing, oat varieties having the spring erect type of seeding growth are considered better than the winter varieties.

**Fertilizer studies with potatoes,** O. SMITH and W. C. KELLY. (Cornell Univ.). (*Amer. Potato Jour.*, 23 (1946), No. 4, pp. 107-135, illus. 10).—Effects of two rates of fertilizer application, three methods of fertilizer placement, three combinations of K sources, and two of N sources on the content of the petioles of the plants of N, P, K, Ca, and Mg, at various times during the growing season, total yield and yield of U. S. No. 1 size tubers, and specific gravity of the tubers of the Green Mountain variety were studied in 1944 on Lordstown silt loam.

Yields of U. S. No. 1 size potatoes resulting from 2,400 lb. per acre applications of 5-10-10 fertilizer averaged 52 bu. per acre more than with 1,200-lb. applications. K source and fertilizer placement method greatly influenced yields obtained from any one rate. Yields were influenced markedly by method of fertilizer placement, that of one-half broadcast, then plowed, one-half in

equal bands at planting time resulting in highest yields. Increases in yields of this method above that of all in bands at planting ranged from 25 to 66 bu. per acre, depending upon rate of application and N and K sources. Yields were influenced further by the K source, that of one-half KCl, one-half sulfate of potash-magnesia, consistently outyielding the other two sources.

The correlation of N content of petioles at each date of sampling with yields was highly significant, additional N being a major single factor causing increased yields of potatoes from 2,400-lb. v. the 1,200-lb. acre rate. Placement of all fertilizer in bands at planting was not so efficient for N uptake by the plant as when part of the fertilizer was broadcasted before plowing or applied on the plow sole. No significant difference appeared in the P content of leaf petioles at any sampling date between any factors studied. Petioles of all treatments contained large quantities of K; evidently enough K was taken up from all treatments to result in high yields.

Correlation of the Mg content of petioles with yields was highly significant. In every case where sulfate of potash-magnesia was in the fertilizer, the Mg content in petioles was highest and yields were also the largest. The increased yields were evidently due to the Mg and not to the sulfate form of potash in the sulfate of potash-magnesia. The amount of Mg in the 1,200 lb. per acre application with 50 percent of the K as sulfate of potash-magnesia (50.5 lb. MgO per acre) sufficed for optimum Mg absorption by the plant and for maximum potato yields under the conditions.

In general, all treatments tending to increase yields tended to decrease the specific gravity of the tubers of those treatments. The specific gravity of tubers grown with one-half the K from KCl and one-half from  $K_2SO_4$  exceeded that of tubers grown with KCl as the sole K source. Plants in plots receiving all of the K as KCl matured and died earlier than did those containing part of the K as sulfate of potash-magnesia, and plants receiving all fertilizer in bands at planting matured and died earlier than those receiving part of fertilizer broadcasted before plowing or applied on the plow sole.

**The residual effect of crop rotations on potato yield and the presence of potato scab.** E. J. WHEELER (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 326-332, illus. 1).—Katahdin potatoes grown at Lake City 1935-44 averaged 154 bu. of U. S. No. 1 tubers per acre in the 4-yr. rotation alfalfa (3 yr.), potatoes; 127 bu. in the 3-yr. sweetclover (2 yr.), potatoes rotation; 97 bu. on the 2-yr. corn (rye seeded at last cultivation), potatoes; and 103 bu. from continuous potatoes. The respective average percentages of scab-free potatoes were 84, 43, 87, and 70 percent. Decline in percentage of clean potatoes from 1935 to 1944 was greatest on sweetclover plots, followed by the check, alfalfa, and rye plots. The merits of a cultural practice recommended to take advantage of the high percentage of scab-free U. S. No. 1 size potatoes on the rye rotation with the higher yields produced on the alfalfa rotation plots were demonstrated.

**Storage conditions which affect the vitamin C content of Maine-grown potatoes.** E. MURPHY. (Maine Expt. Sta.). (*Amer. Potato Jour.*, 23 (1946), No. 6, pp. 197-218, illus. 3).—Recently dug Irish Cobbler, Mohawk, Green Mountain, Chippewa, Katahdin and Sebago potatoes were held at 32°, 36°, 50°, 60°, or 65°, and 70° F. for 7 mo. in 1943-44 and 1944-45 seasons, and were analyzed monthly for vitamin C.

Mohawk showed the highest average value and Chippewa the lowest. An average decrease from 22.7 to 6.3 mg. per 100 gm. took place during the 7 mo., one-third to one-half of the total loss occurring during the first month. The higher temperatures were conducive to larger retention of vitamin C

than were 32° and 36°, although neither 60°, 65°, nor 70° was superior to 50°. Varieties appear to differ in response to temperature and duration of storage. During both years Mohawk remained at a relatively high level and Chippewa at a low one throughout the period. Sebago decreased at a disproportionately rapid rate, whereas Green Mountain tended to improve its position. Although varietal differences diminished greatly under influence of storage, they were not nullified completely. New tubers averaged 10.9 mg. higher in 1944 than in 1943, but after 7 months' storage, the average difference was only 2.3 mg. per 100 gm. Only 36° and 50° maintained tubers of good physical quality. If vitamin C retention is a criterion of quality, 50° would be considered superior to all others tested. References total 29.

**Fertilizing soybeans: Lime, potash, and phosphate are needed,** W. L. NELSON (*Res. and Farming [North Carolina Sta.], 4 (1946), Prog. Rpt. 3, pp. 4-5, 9, illus. 3*).—Fertilizer tests on several soil types indicated that acre yields of 25 to 40 bu. may be expected if needs of the soil for lime, K, and P are supplied. The treatments would vary according to the preceding crop in the rotation.

**Tobacco Substation at Windsor, report for 1945,** P. J. ANDERSON, T. R. SWANBACK, ET AL. (*Connecticut [New Haven] Sta. Bul. 493 (1946), pp. 31, illus. 3*).—In addition to continued investigations with cigar-leaf tobacco (E. S. R., 94, p. 616) noted below, preservation of shade tent poles is noted on p. 669, influence of cover crops on wireworm injury on p. 691, and incidence of diseases in 1945 and control of *Sclerotinia* pole rot, wildfire in the Connecticut Valley, and chloropicrin for sterilization of seedbeds on p. 670. Tables show the acreage and production of Broadleaf, Havana Seed, and shade-grown tobacco in the Connecticut Valley for the years 1942-45 and average for 1932-41, and tobacco stocks on hand and cigar consumption 1933-45.

**Boron in tobacco fertilization,** T. R. Swanback (pp. 5-8).—Where tobacco yields averaged more than 1 ton per acre, yields were not affected by 10 or 20 lb. per acre of borax applied on each side of the row or by 15 or 20 lb. broadcasted. The grading, however, was usually improved where borax was applied, although statistical differences were obtained only when more than 10 lb. per acre was used. In the experiments, the soil was enriched from about 0.5 to a little more than 1 p. p. m. Since 15 lb. of borax broadcasted (together with regular fertilizer), furnishing about 1 p. p. m. of B, produced optimum response, this amount could be applied safely when there is an apparent B need. The author emphasized that this is a one-time application, not to be repeated without a soil test for B content. A continuous use of not more than 5 lb. of borax per ton of fertilizer evidently would be a safe procedure.

**Connecticut fifteen, a root rot-resistant type of shade tobacco,** P. J. Anderson and A. Green (pp. 27-28).—Connecticut 15, a new variety of shade tobacco which shows marked resistance to black root rot, surpasses ordinary shade strains in many other respects. It is very uniform in all of its characteristics, the plants are taller than common shade, producing 20 to 25 marketable leaves as compared to 15 to 18 for ordinary tobacco, and the variety tops out later and is not so inclined to branch into long suckers at the top. The leaves are rounder, more of desirable shape persisting to the uppermost leaf, whereas the leaves in the common type become pointed as they approach the top of the plant. Cured leaves of Connecticut 15 are of a lighter shade and more uniform color, less inclined to exhibit yellow spots, tips, and margins, and the vein is less prominent than in the common type. This means that a larger percentage of the leaves are sorted into the

higher priced grades. Connecticut 15 showed an increase of 34 percent in value per pound over other shade strains in the last 2 yr. Tobacco men growing the new variety report increases in acre yield of marketable leaves ranging from 25 to 50 percent.

**Leaf-burn of tobacco as influenced by content of potassium, nitrogen, and chlorine.** O. J. ATTOE. (Wis. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 186-196, illus. 4).—Nearly all of the variations in the leaf-burn of tobacco collected from farmers' fields in Wisconsin 1939-41 were found to be related to the contents of  $K_2O$ , reduced N (organic and ammonium forms), and Cl. The equation given for the relationship was:  $\text{Log burn in seconds} = -0.009 + 0.583A + 0.473A^2$ , where  $A = 0.913 + 0.295 \times \% K_2O - 0.431 \times \% N - 0.354 \times \% Cl$ . On the basis of the value of their coefficients in this equation, reduced N is 1.46 times more detrimental to leaf-burn than  $K_2O$  is beneficial, and 1.22 times more detrimental than Cl. The coefficient of correlation is 0.921. Amount of exchangeable  $K_2O$  in the soil on which the tobacco was grown greatly influenced the  $K_2O$  content of the leaves and consequently their leaf-burn values. This relationship, for average contents of reduced N and Cl in the leaf, was expressed by the equation:  $\text{Log burn in seconds} = 3.153 - 3.328B + 0.829B^2$ , where  $B = \text{log lbs. exchangeable } K_2O \text{ per acre}$ . According to this equation, there results a leafburn of about 1 sec. for 200 lb. of exchangeable  $K_2O$  per acre, 2 sec. for 600 lb., 4 sec. for 950 lb., 8 sec. for 1,400 lb., 16 sec. for 2,000 lb., and 32 sec. for 2,750 lb.

**Winter wheat varieties for Oklahoma.** A. M. SCHLEHUBER, V. C. HUBBARD, W. M. OSBORN, C. B. CROSS, and R. M. OSWALT. (Coop. U. S. D. A.) (*Oklahoma Sta. Bul.*, 297 (1946), pp. 36, illus. 2).—Cheyenne, Comanche, Pawnee, Tenmarq, and Turkey hard red winter wheat and Clarkan and Fulcaster soft red winter wheat are recommended for Oklahoma on the basis of yields in variety tests at Stillwater, Lawton, and Woodward 1931-45 and in county tests, and milling and baking experiments. Varieties tested are described. Tables show acreage occupied by each important variety and annual and average yields of varieties at each station.

The value of winter wheat for pasture was determined by clipping. At Stillwater, clipping to March 25 produced about 3,000 lb. of green forage per acre, and reduced grain yield about 3 bu. Clipping to April 1 doubled forage production, but the grain yield was only about 5 bu. At Woodward no reduction in grain yield occurred with clipping to March 25, and only slight reduction when clipped to April 1. Clipping after April 1, however, resulted in substantial decreases in grain yield. About 1,700 lb. of green forage was produced when clipped to March 15 and about 3,000 lb. to April 1. Marked varietal differences in grain reduction after clipping or in production of green forage were not apparent at either station.

**Structure, properties, and preparation of certain bast fibers.** H. B. HANSON (*Iowa State Col. Jour. Sci.*, 20 (1946), No. 3, pp. 365-383, illus. 10).—The relative quantity, properties, and extractability of the fiber were studied in *Apocynum cannabinum* (Indian hemp or dogbane), *Cannabis sativa* (hemp), *Asclepias syriaca* (common milkweed), *A. sullivantii* (smooth-leaved milkweed), and *Gonolobus laevis* (climbing milkweed). The quantity of fiber in the stems of these plants justified further study of means of economical commercial production, extraction, and utilization. Their fiber cells were found to have the necessary cell dimensions and to be similar enough to flax fiber to be spun and woven into fabric. Reactions of their fibers to reagents used in care of fabrics were similar to the reactions of flax. The luster and high

quality of the fiber in *Gonolobus* merits study of the cultivation, processing, and utilization of this species. *A. verticillata* (whorled milkweed), also tested, was considered of no value as a source of fiber.

**Production and distribution of foundation seed stocks**, G. L. STOKER (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, p. 20, *illus.* 1).—Foundation seed stocks produced by the Utah Station and released through the Utah Crop Improvement Association include Velvon 11, Trebi, and Winter Club barley; Uton and a new short oats not yet named; Dicklow, Early Baart, Federation and Lemhi spring wheats; Cache and Wasatch winter wheats; Bliss potatoes; and White Sweet Spanish and Yellow Sweet Spanish onions. The association also distributes seed of alfalfa and red clover from other stations.

**Four weed threats**, A. H. HOLMGREN (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, pp. 18–14, *illus.* 4).—Austrian fieldcress (*Roripa austriaca*), camelthorn (*Alhagi camelorum*), St. Johnswort (*Hypericum perforatum*), and yellow star-thistle (*Centaurea solstitialis*), described and illustrated, have been declared noxious by the Utah Board of Agriculture, although they are not yet known to occur in the State. Since their introduction into the United States all four weeds have spread rapidly and are now known in areas close enough to Utah to cause concern.

**Some effects of 2,4-D on ragweed and certain woody plants**, B. H. GRIGSBY (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 304–310, *illus.* 1).—Further experiments (E. S. R., 94, p. 468) showed that ragweed can be killed by a single application of 2,4-D at a concentration of 1,000 p. p. m. Pollen production by old plants can be stopped, without causing immediate death of the plants, by spraying with a concentration of 500 p. p. m. Faster response may be obtained by addition of very small amounts of sodium chlorate or Ammate. Pollen formation may also be prevented by spraying ragweed in the stage of growth just preceding flower-stalk elongation with 250 p. p. m. Plants sprayed in this stage appear to be arrested in development but usually persist until frost, but they produce few seeds. Young growth of poison-ivy is usually killed by 100 p. p. m. of 2,4-D, but older growth may be somewhat resistant. The 2,4-D seems to have slight effect upon mature growth of many woody plants.

**A tropical-weed killer**, D. G. WHITE and A. G. VILLAFANE. (Puerto Rico Federal Expt. Sta.). (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 8, pp. 126–128, *illus.* 3).—Weeds killed with a commercial mixture of 2,4-D included nutgrass (*Cyperus rotundus*), dayflower (*Commelina longicaulis*), caladium (*Caladium* sp.), water-hyacinth (*Eichhornia crassipes*), royal waterlily (*Victoria regia*), and lotus lilies (*Nymphaea* spp.).

## HORTICULTURE

**Advantages and limitations of glass plant protectors in the production of certain vegetables**, E. P. BRASHER (*Delaware Sta. Cir.* 18 (1945), pp. 11, *illus.* 1).—Rejected Pyrex baking dishes placed over hills of sweet corn, tomato, cantaloup, watermelon, and pole lima beans hastened decidedly the germination of all the crops. In the case of the lima beans no germination was obtained in the open, with a perfect stand under the protectors. Soil and air temperatures were higher under the covers, with a difference of 2° to 5° F. registered in the soil at a depth of 4 in.

Early yields were increased with all crops except the watermelons, which were damaged by damping-off fungi. With the cantaloup and tomato the

early advantage in yield persisted so that total yields were significantly higher. However, on an economic basis, the cantaloup was the only crop which would have paid for the added cost.

For the home garden the plant protectors would have a material benefit, provided protectors could be purchased for less than 10 cents. In the home garden it would be more feasible to ventilate the protectors so as to avoid overheating and damping-off troubles.

**Further studies on the response of lettuce to fertilization, A. E. GRIFFITHS and A. H. FINCH** (*Arizona Sta. Bul. 199* (1945), pp. 42+, *illus. 4*).—Band placement of fertilizers in which the material was distributed at time of planting in a band approximately 1 in. wide, 3 in. below the seed, and 1.5 in. to the furrow side resulted in larger heads and greater yields than did the same amounts broadcasted. On soils of good fertility and organic matter content simple chemical fertilizers were efficient. On such soils a fertilizer program of phosphates applied at planting time and nitrogen applied later as a side dressing gave the best results. On such soils band-placed N at time of planting sometimes delayed maturity and made for slimed, soft heads. This was especially true in autumn when high temperatures prevailed. On the other hand, band-placed N with the P at time of planting was generally beneficial for crops growing in the cool winter months and for crops on soil of low fertility. On soil lacking in organic matter the band placement of mixtures containing blood meal or goat manure resulted in better lettuce crops than did chemicals alone.

The general need of phosphate applied at time of planting was again demonstrated, and all sources of phosphorus were equally effective when applied in equal amounts of actual phosphorus. About 70 lb. of band-placed  $P_2O_5$  per acre gave the best results generally. The vigorous growth of lettuce during its early stages was apparently important to the success of the crop.

Organic matter was shown to be of great significance. On a heavy soil depleted of organic matter, 10 tons of corral manure gave results better than were obtained with any chemical fertilizer. Legume green manures were helpful in maintaining organic matter. The absorption of both N and P by the lettuce plant was increased in the presence of abundant organic matter.

**Changes in the Blue Hubbard squash skin during storage and its relation to squash spoilage, M. C. RICHARDS, A. F. YEAGER, and R. C. JONES** (*N. H. Hort. Soc. Jour.*, 9 (1946), pp. 51–56, *illus. 2*).—In 1944, beginning 2 weeks before harvest and continuing periodically into the storage season, sections of the surface tissues were collected from thick- and thin-skinned types of Blue Hubbard squash. In cross section, the skin was found to be composed of a thick layer of cuticle, a distinct epidermal layer, and then a section about 20–25 cells thick of round, thin-walled parenchyma cells. Below this there was a layer of round to elongate parenchyma cells which develop pits and thickened cell walls during storage. Lignification occurs in the cell walls during storage. The process is gradual and much more evident in the thick- than thin-skinned types. Lignification was not an important factor in preventing storage rots, but a prestorage treatment of 14 days in a warm greenhouse was worth while in decreasing subsequent spoilage during storage.

**New strawberry looks good, E. B. MORROW.** (Coop. U. S. D. A.). (*Res. and Farming* [North Carolina Sta.], 4 (1946), *Prog. Rpt. 3*, p. 2, *illus. 2*).—In a test of 15 strawberry varieties at the McCullers Branch Station, Midland, a new variety released recently by the U. S. Department of Agriculture, outyielded all other varieties, producing at the rate of 278 crates per acre as compared with 191 crates for Blakemore and Massey. However, in trials at

the Coastal Plain Branch Station Midland was surpassed in yield by other varieties including Fairfax and NC 1039. In both the 1945 and 1946 season NC 1039 has outyielded both Blakemore and Massey at the Coastal Plain Station and appears to have much promise. At the Coastal Plain Station seven kinds equaled but did not surpass Massey in size. Of the named varieties Blakemore and Massey appear best for the Coastal Plain region.

**Effect of oxygen concentration on respiration of the Fuerte avocado fruit,** J. B. BIALE. (Univ. Calif.). (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 363-373, illus. 10).—Certain relationships were observed between the effects of oxygen and temperature on the respiration rates of Fuerte avocado fruits taken from 6- to 7-year-old trees on the Los Angeles campus of the University of California. At low temperatures the effects of O<sub>2</sub> concentrations are minimized, with the consequence that the temperature coefficient ( $Q_{10}$ ) was markedly different for the several O<sub>2</sub> levels. Thus at 2.5 percent O<sub>2</sub>, the  $Q_{10}$  for the minimum respiratory rates in the range of 5° to 15° C. had a value of two, while the corresponding  $Q_{10}$  magnitude in air was two and one-half times as high. At 2.5 percent O<sub>2</sub> it took approximately twice as long for the fruit to soften as in air. The total amount of CO<sub>2</sub> given off by the fruit during the period ending with the climacteric peak was found to be approximately constant for the several modified atmospheres at 15°.

The effects of O<sub>2</sub> tension on respiration were markedly modified by temperature. Fruit softening was found to be closely related to the respiration trends.

**Physiology of citrus fruits in storage,** E. V. MILLER. (U. S. D. A.). (*Bot. Rev.*, 12 (1946), No. 7, pp. 393-423).—This critical review (75 references) discusses the changes taking place during ripening, after harvest, and in cold storage, respiration, physiological disorders occurring during storage and their development over that period, factors influencing the incidence of low temperature injuries, methods for preventing low-temperature break-down, CO<sub>2</sub> storage, and ethylene treatment. "If a concise recommendation for storing citrus fruits is desired, it can be expressed as follows: Eliminate insofar as practicable the prestorage conditions that have been described in this paper as undesirable. Select the temperature recommended for the particular type of fruit and attempt to maintain optimum conditions in storage. If the loss of moisture is being retarded by the use of moisture-proof wrappers, inclusion of a suitable disinfectant in the wrapper is highly desirable. Make periodic inspections of the stored fruit in order to terminate the storage at the very first symptoms of development of physiological disorders."

**Saving Puerto Rican coffee soil,** E. A. TELFORD (U. S. Dept. Agr., *Agr. in Americas*, 6 (1946), No. 8, pp. 118-121, illus. 4).—The history of coffee production in Puerto Rico is presented, together with information as to present status, the role that the Soil Conservation Service is playing in developing plantations on steep hillsides, and data on the yields on well-managed plantations obtained by the University of Puerto Rico. Results on run-off plots in Mayaguez indicate that areas in coffee which are protected by terraces, crop residues, and good ground cover lose less soil and moisture than do similarly located plots of sugarcane, Bermuda grass, or clean-tilled crops.

**Tea in place of gold,** K. WERNIMONT (U. S. Dept. Agr., *Agr. in Americas*, 6 (1946), No. 8, pp. 115-117, illus. 2).—With a total of some 4 million bushes, yielding an estimated 175,000 lb. of processed black tea, tea production has attained a position of great importance in the State of Minas Geraes, Brazil, and adjoining areas. This article discusses the terrain, methods of culture, harvesting, processing, and handling of the product.

The jack fruit (*Artocarpus integra*, Merrill), its planting in Coconut Grove, Florida, D. FAIRCHILD (*Fairchild Trop. Garden, Occas. Paper No. 16 (1946)*, pp. 14, illus. 8).

Grass oil from Guatemala, G. S. QUATE (*U. S. Dept. Agr., Agr. in Americas*, 6 (1946), No. 8, pp. 122-125, illus. 7).—The production of volatile oils from highly scented grasses has become an important industry in Guatemala. This article discusses the production of citronella and lemon grass, with notes on development of the industry, harvesting and planting, processing, and general problems.

## FORESTRY

A Spanish-English glossary of forestry terminology, I. C. GARCIA-PIQUERA (*U. S. Dept. Agr., Forest Serv., Caribbean Forester*, 7 (1946), No. 2, pp. 103-120).—About 100 terms are here defined, with a partial bibliography of sources.

Good forest management to meet timber requirements of post-war era and future, M. PAYNE (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, pp. 1, 5, illus. 1).—A discussion is presented of the timber supplies in the United States as a whole and in Mississippi in particular where, during the war years, the annual cut has been greater than the annual growth. The author outlines better management and cutting practices which would maintain Mississippi forest lands in a permanently productive status and at the same time insure the timber owner a maximum return.

Specifications for aerial photographs used in forest management, S. H. SPURR and C. T. BROWN, JR. (*Photogrammetric Engin.*, 12 (1946), No. 2, pp. 131-141, illus. 2).

A sectional pole for measuring tree heights, F. G. LIMING. (U. S. D. A.). (*Jour. Forestry*, 44 (1946), No. 7, pp. 512-514, illus. 1).—A description is presented of a measuring pole designed to meet the need for a convenient instrument for making periodic height measurements of young trees.

Effect of chemical treatments on the germination of forest tree seeds, L. P. V. JOHNSON (*Forestry Chron.*, 22 (1946), No. 1, pp. 17-24).—A number of chemicals were tested in comparison with stratification and presoaking for their effects on germination of forest tree seeds. The most striking acceleration was obtained from potassium nitrate treatments applied to seeds of *Picea glauca* and *P. rubens*. Significant increases in percentage germination were obtained from potassium nitrate in *Betula lenta*, *B. papyrifera*, *Fraxinus excelsior*, *P. abies*, *P. glauca*, *P. rubens*, and *Pinus resinosa*; from thiourea in *Larix decidua*, *Picea abies*, *P. glauca*, and *P. rubens*; from ethylene chlorhydrin in *Betula lenta*, *B. papyrifera*, *Fraxinus excelsior*, *Larix decidua*, and *Pinus resinosa*; from red copper oxide in *Pinus resinosa*; and from zinc oxide in *Betula papyrifera*, *Picea glauca*, *Pinus banksiana*, and *P. resinosa*.

In general stratification proved more effective than the chemical treatments, but it is pointed out that much is yet to be learned about the proper use of chemicals whereas stratification has many years of background.

In a few instances the simple soaking of seeds in water for a 24-hr. period gave good results. There was some evidence in some instances that a part of the beneficial effects of chemicals could be traced to their protective influence against damping-off organisms.

Seasonal progress of rooting of Norway spruce cuttings, N. H. GRACE and J. L. FARRAR (*Jour. Forestry*, 44 (1946), No. 5, p. 376).—Observations at Pembroke, Ontario, on the development of dormant cuttings taken from the

lower part of 20-year-old trees and set in outdoor frames in November 1940 showed that 25 percent had callused by the end of the following June and by mid-July 80 percent had rooted. The percentage of rooting reached a final value of 95 percent in early September. By September 23, root growth had ceased. The buds developed into new shoots on less than one-half of the cuttings.

**Ecological changes due to thinning red pine, K.-H. CHIO.** (Univ. of Minn.). (*Jour. Forestry*, 44 (1946), No. 5, pp. 369-371).—During the growing season of 1936 and 1937 a comprehensive study of environmental factors was conducted in four thinning plots established in 1927 in a 15-year-old red pine stand at the Cloquet Forest Experiment Station (Minnesota). Growth measurements indicated that the best growth for the selected crop trees occurred in the 6 x 6 ft. spacing. At this distance trees could be permitted to grow for at least 25 yr. without further thinning. The 7 x 7 ft. spacing was second, the 4 x 4 third, and the 9 x 9 least desirable. Measurements at weekly intervals with a photometer at 12 points in each plot showed respective averages of 15.4, 16.5, 36.1, and 60.2 percent of full sunlight in the 4 x 4, 6 x 6, 7 x 7, and 9 x 9 ft. spacings.

**Ponderosa pine in the second cutting cycle, G. A. PEARSON.** (U. S. D. A.) (*Jour. Forestry*, 44 (1946), No. 5, pp. 354-368, illus. 9).—A 480-acre sample plot in the Fort Valley Experimental Forest, Arizona, logged in 1909 and again in 1939 was remeasured in 1944 for the first 5-yr. record in the second cycle. Net annual increment per acre declined from a high of 115 bd. ft. per acre in the second 5-yr. period (1914-19) to 52 ft. in the sixth period (1934-39). According to the 20-yr. trend before cutting, the net annual increment would have declined further to about 40 bd. ft. in 1944 but rose instead to 67 ft. notwithstanding a reduction in the volume of growing stock by 50 percent. Analyses of trends before and after the second cutting indicate that if the second cut had been made 10 yr. earlier the net increment today would be at least 50 percent higher than it is. Comparison of three methods of cutting indicates that marking should be governed by silvicultural principles applied to each tree rather than a blanket system. Good dominants should not be sacrificed in favor of poor subordinates. Enough relatively large trees should be left to provide for the next cut.

**Pruning forest trees by the finger-budding method, J. D. CURTIS.** (Univ. Maine). (*Jour. Forestry*, 44 (1946), No. 6, pp. 502-504).—Removal of lateral buds near the terminal shoot with a view to obtaining knot-free lumber was tested under Maine conditions. Certain preliminary conclusions were reached, for example, that species whose terminal bud is subject to insect or other injury are not adapted to hand disbudding and that damage as leaders from climatic agencies may be expected in exposed locations. There is indicated a need of further observations.

**Tree pruning by annual removal of lateral buds, B. H. PAUL.** (U. S. D. A.). (*Jour. Forestry*, 44 (1946), No. 7, pp. 499-501, illus. 1).—Tests conducted in the Nicolet National Forest in Wisconsin indicated certain advantages and disadvantages in the pruning of red pine, *Pinus resinosa*, by the annual removal of the lateral buds that cluster about the terminal bud. The first few sets of laterals were allowed to grow in order to nourish the young tree during the years of treatment.

A modified treatment is suggested in which the lateral buds are permitted to make 1 year's growth before removal.

**Susceptibility of beech to drought and adverse winter conditions, P. SPAULDING.** (U. S. D. A.). (*Jour. Forestry*, 44 (1946), No. 5, p. 377).—The author

reports the occurrence of winter injury to beech and other hardwoods in the Adirondack and nearby Lake State areas in 1934 and in Vermont and Maine in 1943. Both incidents were noted in periods when summer droughts were followed by winters of adversity.

**The lignin, ash, and protein content of some neotropical woods, F. J. MARCHAN.** (P. R. Univ. Expt. Sta.). (*U. S. Dept. Agr., Forest Serv., Caribbean Forester*, 7 (1946), No. 2, pp. 135-138, 150; *Span. abs.*, p. 150).—Analyses by the Waksman-Stevens method for lignin in soils (E. S. R., 59, p. 717) are tabulated for about 40 species of neotropical and other woods, together with data on their ash and protein contents and resistance to termite attack.

**The physical-mechanical properties of certain West Indian timbers, I, R. W. WELLWOOD** (*U. S. Dept. Agr., Forest Serv., Caribbean Forester*, 7 (1946), No. 2, pp. 151-189, *illus.* 9; *Span. abs.* pp. 174-189, *Fr. abs.* p. 189).—This paper deals with the properties of tabonuco (*Dacryodes excelsa* Vahl), a native of the montane forests of Puerto Rico, and the most important timber tree of that Island. Tabonuco wood has interlocked grain and a ribbon-type figure. Seasoned heartwood, which has a lustrous brown color, planes and finishes well. At present it is used locally for furniture, carpentry, and construction. Although it is not highly regarded as a first-class timber, its superior strength properties and attractive appearance merit wider use in cabinetry, furniture, and interior trim and it should produce attractive veneers.

**A convenient method for cold-soaking fence posts in a pentachlorophenol solution, R. W. LORENZ.** (Univ. Ill.). (*Jour. Forestry*, 44 (1946), No. 7, pp. 520-522, *illus.* 1).—Specifications and cost data are presented for a simple plant for treating fence posts by the cold-soaking method using pentachlorophenol dissolved in fuel oil.

**Preservation of shade tent poles, H. W. HICOCK and P. J. ANDERSON** (*Connecticut [New Haven] Sta. Bul.* 493 (1946), pp. 8-14, *illus.* 1).—With the passing of the chestnut, several other species, including white cedar, red cedar, black locust, and oak, were tried as post material with rather unsatisfactory results. Tests were made of various preservatives and methods of treatment that might prolong the life of posts. Superficial treatments by brushing, dipping, or spraying did not penetrate the wood and are reported as of little value in preservation.

Treatment of the butts in hot and cool creosote prolonged life to 15 yr. as compared with 5 yr. for untreated. Pressure treatments, tried with various chemicals, gave promising results. Freshly cut posts were treated by the sap-stream method with copper sulfate, sodium fluoride, and zinc chloride. In this process the sap is replaced under gravity or head pressure by a chemical solution. After 6 yr. the zinc chloride-treated posts showed no deterioration.

**A method of measuring checks in veneer, J. P. LIMBACH.** (U. S. D. A.). (*Jour. Forestry*, 44 (1946), No. 7, pp. 509-511, *illus.* 3).—This article describes a method of measuring the depth and length of checks in veneer and of determining the number per unit of area.

## DISEASES OF PLANTS

**The recruitment and training of plant pathologists in Great Britain: A report prepared by the Plant Pests and Diseases Committee and adopted by the Council of the Association of Applied Biologists** (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 119-123).

[Plant disease work] (*Connecticut [New Haven] Sta. Bul.* 493 (1946), pp. 16-27, 29-31, illus. 2).—The following brief reports are included: Tobacco diseases in 1945 and studies on pole rot—IV, sclerotina rot (E. S. R., 89, p. 457), both by P. J. Anderson; wildfire returns to the valley; and chloropicrin for sterilization of tobacco seed beds, by T. R. Swanback and Anderson.

**Plantesygdomme i Danmark 1942 [and 1943]: Oversigt, samlet ved Statens plantepatologiske Forsøg** (Plant diseases and pests in Denmark 1942 [and 1943] (*Tidsskr. Plantearb.* 48 (1943), No. 1, pp. 1-90, illus. 4, English abs. pp. 87-90; 49 (1944), No. 1, pp. 1-72, illus. 3, Eng. abs. pp. 68-72).—A summary of physiological, virus, fungus, and bacterial diseases and of insect pests of plants.

**Index to Supplements 152-159, 1945** (*U. S. Dept. Agr., Plant Disease Rptr.*, 1946, Sup. 160, pp. 225-233+).

**Present-day quarantine emergencies**, C. J. DRAKE (*Amer. Nurseryman*, 83 (1946), No. 9, pp. 13-14, 45-46).—An address, as president of the Central Plant Board, at its meeting in St. Louis, March 25, 1946.

**A contribution to the fungus flora of Utah and Nevada**, A. S. RHODS (*U. S. Dept. Agr., Plant Disease Rptr.*, 1946, Sup. 162, pp. 67-99+).—The fungi listed comprise miscellaneous collections made during the latter part of 1944 and the first half of 1945; records from a few collections by others and turned over to the author for determination are also included by reason of their interest. Unless otherwise stated, the fungi included in this annotated list were collected in Utah and by the author. Specimens of these fungi have been deposited in the Mycological Collections of the Department and duplicates of most of them also with the Utah Experiment Station.

**Notes on seed-borne fungi**.—IV, *Acremonia*, *Chlamydomyces*, and *Trichocladium*, J. W. GROVES and A. J. SKOLKO (*Canad. Jour. Res.*, 24 (1946), No. 3, Sect. C, pp. 74-80, illus. 8).—In these notes (E. S. R., 93, p. 725), *A. atra*, *A. verrucosa*, *C. palmarum* and *T. asperum*—isolated from agricultural seeds—are described and illustrated; these fungi did not appear to be significant pathologically.

**Synchytrium decipiens and Synchytrium chrysosplenii**, M. T. COOK. (La. State Univ.) (*Mycologia*, 38 (1946), No. 3, pp. 300-305, illus. 3).—The author describes and illustrates the histopathology of *S. decipiens* on leaves, petioles, and stems of *Amphicarpa monoica* and of *S. chrysosplenii* on leaves of *Chrysosplenium americanum*.

**Isolation of Thielaviopsis basicola from soil by means of [living] carrot disks**, C. E. YARWOOD. (Univ. Calif.). (*Mycologia*, 38 (1946), No. 3, pp. 346-348).

**Copper 8-quinolinolate, a promising fungicide**, D. POWELL. (Univ. Ill.). (*Phytopathology*, 36 (1946), No. 7, pp. 572-573).—Preliminary laboratory tests with derivatives of 8-quinolinol against *Sclerotinia fructicola* gave promise of the fungicidal efficiency of copper 8-quinolinolate. In subsequent preliminary field tests on 30-year-old Duchess apple trees this compound compared favorably with Fermate and Puratized N5-E against apple scab and blotch; commercial control was not secured with Isothan Q 15 or Q 32. Fruit maturation appeared to be directly correlated with the degree of fungus infection rather than with the chemical treatment used. No visible chemical injury to fruit or foliage resulted under the conditions of this test.

**The cereals root eelworm Heterodera major** (O. Schmidt) Franklin in North Wales, I. THOMAS, E. B. BROWN, and R. J. WILLIS (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 63-65, illus. 3).—*H. major* is shown to be locally distributed in North Wales, the most heavily infested areas being in the arable

districts of the eastern counties. The most severe attacks were on oats, where the crop had been grown too frequently; wheat and barley appeared to be unaffected at the cyst populations encountered.

**Eyespot of wheat and barley in Scotland in 1944.** M. D. GLYNNE (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 35-39).—In August 1944, *Cercospora herpotrichoides* infection was found in 90 of 121 fall-sown wheat crops distributed over 12 Scottish counties, was abundant enough in 40 fields probably to harm later crops, and was causing obvious loss in 11 crops. The disease was also found in 17 of 18 spring-sown barley crops. Eyespot increased with the frequency of wheat and barley in the 2 yr. preceding, but a few infected crops occurred on fields not in these grains for many years. In Scotland, where there is greater humidity, eyespot tends to increase more rapidly than in similar rotations in England; lesions are found higher up on the straw, and the disease is more prevalent on spring-sown barley. The long rotations practiced in Scotland prevent more extensive damage by eyespot.

**Response of spring barley varieties to floral loose smut inoculation.** H. L. SHANDS and C. W. SCHALLER. (Wis. Expt. Sta.). (*Phytopathology*, 36 (1946), No. 7, pp. 534-548).—Several methods of inoculating barley varieties with loose smut were compared. The most effective and easily manipulated technic consisted of injecting dry spores into the flowers via a hypodermic needle attached to a small rubber bulb containing chlamydospores; this "needle" method was used in testing the reactions of 300 barley varieties from the C. I. collection. Wide varietal differences in percentage of infection were found, several being highly resistant; Abyssinia was the source of more resistant varieties than any other country. The loose smut reactions of several commercial varieties are given; also listed are 17 varieties that had less than 15 percent of stripe and loose smut. In tests of many smooth-awned selections from the breeding program, some having fairly good agronomic type have proved resistant.

**Una nueva enfermedad del haba (*Vicia faba* L.) en el Perú** [A new disease of broadbean in Peru], C. BAZAN DE SEGURA (*Agronomía [Lima]*, 10 (1945), No. 42, pp. 49-52, illus. 3; *Eng. abs.*, p. 52).—The existence of a new disease of broadbean ascribed to *Phoma* sp. is reported for Peru.

**The slurry method for treating seed corn.** G. F. MILES (*Agr. News Letter*, 14 (1946), No. 4, pp. 71-74).—Seed processors, aided by manufacturers of seed-treating chemicals and equipment, are making substantial progress in overcoming some of the obstacles to economical, safe, and efficient seed-treating operations. An example is the recent development of a new and superior method of treating seed corn which required the designing and constructing of a new type of seed treater as well as the development of a new chemical formulation. The new method—called the slurry method—involves application of the disinfectant to the seed in the form of an aqueous suspension or slurry instead of as a dust or powder. In a field test in Iowa (1945) under very unfavorable soil conditions as to temperature and moisture the average percentage increase in stand over untreated seed was 79.4 for the slurry method and 67.2 for the Arasan dust. Again, under the severe conditions of 1945 in Illinois, 12 lots of hybrids gave an average percentage increase in stand over untreated seed of 305.7 for the slurry and 279 for the Arasan dust.

**Lespedeza anthracnose.** J. L. WEIMER. (Ga. Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 36 (1946), No. 7, pp. 524-533, illus. 3).—The author describes an anthracnose of annual lespedeza caused by a strain of *Glomerella cingulata*, which induces more or less circular, elliptical, or angular brownish lesions from 1 to 5 mm. in diameter on the leaflets. The number of spots per

leaflet may vary greatly, but one is sufficient to cause a leaflet to fall. The lesions on petioles and stems are dark brown to nearly black and vary from circular to linear; they are important principally on young seedlings, since the stems may be completely girdled. The disease may be very prevalent in local areas during wet periods, especially in the late spring and early summer months; it may disappear during subsequent dry spells. Strains of *L. striata* appear to be more susceptible than those of *L. stipulacea*, although some of the latter are moderately so. It is believed that—should control measures become necessary—resistant varieties may be found among some of the strains of the latter species, such as F. C. 31249.

**Field trials of copper fungicides for the control of potato blight.—II, Spray retention.** E. C. LARGE, W. J. BEER, and J. B. E. PATTERSON (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 54–63, illus. 2).—In this study (E. S. R., 95, p. 68), spray-retention estimates were made during four seasons in England on main-crop potatoes sprayed with about 120 gal. per acre for the first and 160 gal. for the second application. Evidence is given on the limits of reliability of the disk method of leaf sampling, and an alternative method—battery washing—is described. With 2.5 to 3.5 in. of rain over test periods of 3 to 4 weeks, 1 percent bordeaux gave about 40 percent spray retention; cuprous oxide and copper oxychloride sprays at the same Cu dosage but compounded with sulfite lye or other water-soluble dispersing agent showed less than 20 percent retention. Compounding these materials with a bentonite improved the retention. The percentage retention of 0.5 percent bordeaux proved to be less than that of the usual 1 percent formula, but adequate spray deposits could be maintained with this and other low-Cu fungicides by more frequent applications. A rapid method for determining total foliage expanse is described, and the importance of such determinations in connection with spray-retention trials and practical spray timing is stressed. In tests to determine whether Cu is absorbed by potato leaves from the spray deposits, absorption—or acid-resistant adsorption—of the order 0.02 mg. Cu per 120 sq. cm. of leaf area was indicated.

**Soft rot of potatoes in 1945 crops.** F. T. BENNETT (*Agriculture, Jour. Min. Agr. [Gt. Brit.]*, 53 (1946), No. 2, pp. 56–58).—An epidemic of soft rot in potato tubers was observed in widely separated districts of England in November 1945; from typical specimens an organism of the *Bacterium carotovorum-phytophthorum* type was isolated. The epidemic was associated with immature tubers, the immaturity being a result of seasonal conditions; the earlier the harvesting, the greater was the liability to rotting. The rot spread among immature tubers under lack of air, high temperature, moist air, and pressure. Sound tubers sorted out of consignments or clamps—after the necessary maturation period—were safely used for seed. Killing of the haulm by spraying—followed by the requisite period for maturation of the tubers in the soil—is recommended; this also reduced the incidence of late blight, which itself predisposes to soft rot.

**Varietal differences in susceptibility to potato virus Y.** F. C. BAWDEN and B. KASSANIS (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 46–50).—Besides giving different kinds of symptoms when infected with this virus, individual potato varieties also differed in their susceptibility, in the virus concentration attained in their sap, and in their efficiency as virus sources for aphids. Their relative susceptibility in the open when exposed to equal chances of infection was correlated with the ease with which they became infected when colonized with infective aphids and could be assessed from tests made under glass. Methods for making such tests are described; they need few tubers and are

said to give reproducible results. It is considered that they could be applied in studying the inheritance of this type of resistance and to test the behavior of new seedlings. The variety Katahdin proved the most resistant of any tested, but there were significant differences among commercial British varieties. In the open, all varieties were equally colonized by aphids, and resistance to infection with virus Y was not correlated with resistance to leaf roll.

**Verticillium wilt of sainfoin**, I. ISAAC (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 28-34, illus. 6).—A wilt disease of sainfoin caused by *Verticillium dahliae* is described, and it is shown that the fungus can penetrate seedlings through unwounded roots as well as through ruptures from the emergence of lateral rootlets. The fungus was isolated from spontaneously infected soil only in June-August, though *V. nigrescens* was obtained throughout the year. Comparative studies of the longevity of these two fungi and *V. albo-atrum* proved them all to be viable for at least 3 yr. on agar media. On sterilized wheat grains *V. dahliae* died within 8 weeks after inoculation, *V. albo-atrum* and *V. nigrescens* within 12 weeks, and the hyaline variants of the first two after 6 mo. Evidence was obtained that in artificially inoculated soil *V. dahliae* persists mainly as microsclerotia; it may also exist in the soil as hyaline mycelium or conidia, but for only a relatively short time. The incidence of this disease of sainfoin was reduced by increasing the soil-water content, but was unaffected by applying lime.

**Seed transmission of bacterial blight of sugar beet**, P. A. ARK and L. D. LEACH. (Univ. Calif.). (*Phytopathology*, 36 (1946), No. 7, pp. 549-558, illus. 1).—Bacterial blight—caused by *Phytomonas aptata* and previously described as a leaf spot of sugar beet—is here shown to involve also a blighting of the leaves, black streaking of the seed stalks, and internal root necrosis. Seed from blighted stalks were found heavily contaminated with the bacterium and produced diseased plants on germination. Seed transmission was prevented by using a New Improved Ceresan dust or dip, or an Arasan dust. Swiss chard and broadbean are added to the plants previously reported to be susceptible.

**Some causes of chlorosis and necrosis of sugar-beet foliage**, J. B. HALE, M. A. WATSON, and R. HULL (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 13-28, illus. 15).—Experiments in which diagnosis was confirmed by serological and spectrochemical methods revealed that the two most easily confused diseases—sugar beet virus yellows and Mg deficiency—can be visually distinguished. Yellows reduces the K, but slightly increases the Mg, content of the leaves. Mg-deficiency symptoms are associated with a low Mg content of the foliage, but may be induced by salt applications without greatly affecting the Mg analysis. K-deficiency symptoms are often but not necessarily associated with a low K analysis and may actually be caused solely by a deficiency in Na. In the field, symptoms are induced by  $(\text{NH}_4)_2\text{SO}_4$  and phosphate applications and may be prevented in some cases by applying either salt or muriate of potash; in others, by salt only. Some interchangeability of the functions of K and Na in the plant is suggested. Mn-deficiency symptoms are associated with a low Mn content of the leaves which can be readily increased by spraying or injecting  $\text{MnSO}_4$  solution, but a high concentration of Mn in the foliage—such as sometimes occurs naturally on acid soils—has a toxic effect.

**La pourriture visqueuse de la betterave gelée—l'agent producteur de la fructosane**, *Phytomonas betae-gelatae* n. sp. [The viscous rot of frozen beets—the agent producing fructosan, *P. betae-gelatae*, n. sp.], B. DELAPORTE and H. BELVAL (*Compt. Rend. Acad. Sci. [Paris]*, 202 (1946), No. 17, pp. 1011-

1018).—The authors describe *P. betae-gelatae* n. sp., considered nonpathogenic in the sense that it invades only those tissues killed by cold or heat.

**Disease testing and initial seedling selection work at the Houma Station during 1945**, E. V. ABBOTT and E. M. SUMMERS. (U. S. D. A.). (*Sugar Bul.*, 24 (1946), No. 18, pp. 137A-138A).—A brief progress report on the sugarcane disease situation in commercial varieties, principal crosses studied, and seedlings under pathology test in 1945 (E. S. R., 94, p. 72) at Houma, La.

**An electron microscope study of tobacco mosaic virus at different stages of infection**, T. E. RAWLINS, C. ROBERTS, and N. M. UTECH. (Univ. Calif.). (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 356-363, illus. 8).—Electron microscope studies confirmed E. L. Spencer's sedimentation studies indicating that purified tobacco mosaic virus preparations from leaves infected for 5 days usually contained a higher proportion of double-length particles than did similar virus preparations from leaves infected 20 days. It was not found possible to prove definitely whether the double-length particles resulted from gradual elongation of virus particles while in the host or from end-to-end aggregation of two typical particles having a length of about 300 m $\mu$ ; most of the evidence appeared to favor the latter explanation. The prevalence of particles longer than 450 m $\mu$ . in 5-day virus may explain the results of W. M. Stanley and of Spencer in which they found fewer local lesions induced by a given weight of purified 7- and 5-day viruses than by the same weight of 28- and 20-day viruses. The authors' findings indicate that purification by alternate high- and low-speed centrifugation while the virus is suspended in dilute phosphate-HCl solution causes less end-to-end aggregation than similar purification of virus suspended in distilled water. A very high proportion of tobacco mosaic virus particles regularly have a length around 300 m $\mu$ ; their length appeared to have been very accurately controlled by some factors keeping the length within narrow limits but not producing particles of exactly the same length. The evidence available indicates that particles of this length were present in the host plant. It appears improbable that these particles—showing so little variation in length—have been formed by the end-to-end aggregation of shorter virus particles. Storage of purified virus for about 12 mo. in distilled water at 1° C. failed to cause any detectable aggregation of particles.

**Rust and phosphorus distribution in wheat leaves**, D. GOTTLIEB and J. M. GARNER (*Phytopathology*, 36 (1946), No. 7, pp. 557-564, illus. 1).—No consistent differences in total content of radiophosphorus were observed between entire rusted (*Puccinia graminis tritici*) v. healthy wheat leaves. In inoculated leaves the differences in P content between the infected distal portion and the noninfected basal portion of the leaves were much greater than the differences of similar areas in healthy plants, the distal parts always containing more P. The P was accumulated in rusted parts of leaves and concentrated in the invaded areas. The concentration of radiophosphorus in the urediospores was less than in the leaves.

**Studies on vegetable seed treatments in 1944: Report by Vegetable Seed Treatment Sub-committee of the Seed Treatment Committee of the American Phytopathological Society** (U. S. Dept. Agr., *Plant Disease Rptr.*, 1946, Sup. 161, pp. 66+).—During 1944, 236 uniform seed treatment tests were conducted by 40 cooperators in 29 States and 2 Canadian provinces on 10 vegetable crops (edible soybeans, beets, carrots, cucumber, lettuce, onions, peas, spinach, sweet corn, and tomato) as part of a cooperative project started in 1940. In each case seeds from a single lot were treated by a crop leader at specified dosages and in a uniform manner with 3 or more seed protectants

and distributed to cooperators who conducted germination tests in soil using 5 replications of 100 seeds each. The detailed results for the several crops are here presented separately by the respective crop leaders, and are also briefly summarized by the committee.

**Reducing the loss from disease in the home garden**, J. T. PRESLEY (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, pp. 1, 6).—A brief outline of diseases of the principal home garden crops, with recommended control by resistant varieties or protectants for seed or plant treatment.

**DDT residues on fruits and vegetables**, G. D. MANALO, R. HUTSON, and E. J. BENNE (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 272-280; also in *Canner*, 103 (1946), No. 2, pp. 10-11, 22).—The preliminary findings from this investigation are reported to have shown conclusively that DDT sprays and dusts left varying amounts of residue which bore no direct quantitative relationship to the number of applications. Moreover, the amount of residual DDT failed to decrease proportionately with the length of time between the last application and harvest. Hence, analysis for the amount of DDT in a food is the only safe guide for determining whether it is fit for human consumption. The development and adaptation of methods for the chemical determination of DDT are believed not to have kept pace with the extensive investigations of its effectiveness as an insecticide; numerous aspects of the residue problem still require study.

**The facts about disease resistant vegetables**, J. D. WILSON (*Home Garden*, 7 (1946), No. 2, pp. 19-23).—The author lists varieties known to be resistant to certain plant diseases among the following types of vegetables: Asparagus, beans, beets, cabbage, carrots, celery, corn, cucumbers, eggplant, lettuce, muskmelon, onions, peas, peppers, potatoes, spinach, sweetpotatoes, squash, tomatoes, and watermelons.

**Bud, blossom, and pod drop of canning string beans reduced by plant hormones**, E. H. FISHER, A. J. RIKER, and T. C. ALLEN. (*Wis. Expt. Sta.*). (*Phytopathology*, 36 (1946), No. 7, pp. 504-523, illus. 2).—Various hormones were tried in Wisconsin to prevent bud, blossom, and small pod drop of canning beans and consequent reductions in yields. As a laboratory screening technic to test the abscission-prevention abilities of hormones, abscission layers were readily induced on bean plants by treating with illuminating gas, 1 part in 135 parts of air, for about a day at 84° to 86° F.  $\alpha$ -Naphthaleneacetic and 2,4-dichlorophenoxyacetic acids were the most promising hormones employed. Too strong concentrations not only prevented the formation of abscission layers but also induced a vein clearing, distortion, and dwarfing of leaflets suggesting virus infection. *Lygus oblineatus* induced bud, blossom, and small bean drop and distorted and dwarfed small leaflets of caged greenhouse and field plants; some of this damage was prevented by dusting with  $\alpha$ -naphthaleneacetic acid. An increase of about 18 percent in yield of field-grown wax beans was secured in 1942 with two applications of dust containing  $\alpha$ -naphthaleneacetic acid at 70 p. p. m. in one case and at 140 p. p. m. in another; rain soon followed both applications. Dust on Refugee beans and spray on both Refugee and wax beans were not helpful. Field trials in 1943 showed 24 and 12 percent yield increases, respectively, of wax beans with two applications of dusts containing  $\alpha$ -naphthaleneacetic acid at 40 and 80 p. p. m. but showed a decrease with dusts at 160 p. p. m. and with sprays. Yield increases were due to a greater number of small high-grade beans rather than to larger beans.

**Lygus bug injury of lima bean in California**, K. F. BAKER, W. C. SNYDER, and A. H. HOLLAND. (*Univ. Calif. et al.*). (*Phytopathology*, 36 (1946),

No. 7, pp. 493-503, illus. 2).—California-grown large and baby lima beans usually have a necrotic pitting of the seed indistinguishable from infection by *Nematospora* except for the absence of the pathogen in the lesions. As much as 16.1 percent of the seed has been pitted, with up to 52 punctures per seed; similar damage occurs on blackeye cowpea. Field and greenhouse tests demonstrated the pits to result from toxic feeding of *Lygus* bugs (*L. hesperus*, *L. elisus*, and perhaps others). The insects also cause a serious shedding of blossoms and small pods and some shriveling of the young seeds. Reduction of the injury by an application of DDT dust resulted in significant increases in number of pods, number and weight of beans, and percentage of unpitted seeds. Injury tended to be worst in fields adjacent to established perennial favored hosts, e. g., sugar beets and alfalfa. In some areas the bugs may be present for a relatively short time on lima beans, injuring only part of the pods set or only a portion of a field; in other areas the pest remains active throughout the season, injuring most of the pods in whole fields. The possible involvement of an insect toxin in the lima bean yeast spot of other areas seems not to have been excluded. There are 30 references.

**Phomopsis fruit rot of eggplants: Seed treatment and other methods of control** (*New Jersey Stat. Plant Disease Notes*, 23 (1946), No. 3, pp. 9-12).—*Phomopsis vexans* is so deep-seated in the seed that chemical treatments have proved ineffective, as did also aging of the seed. On the other hand, seed treated in hot water at 50° C. for 50 min. or at 55° for 15 min. were freed of the pathogen; if planted in clean seedbeds infection from this source is thus eliminated, though the seedlings may become infected from contaminated refuse or from soil- or wind-borne spores. Several other methods of reducing the disease are noted, though none of them have proved very effective.

**The effect of seed treatment and dates of seeding on the emergence and yield of peas**, R. J. LEDINGHAM (*Sci. Agr.*, 26 (1946), No. 6, pp. 248-257, illus. 1).—Seed treatment of garden peas proved conducive to increased emergence and sometimes to increased yields at Saskatoon, Sask. The early-sown peas emerged better than the later, and seed treatment had its greatest effect on the later. With total yields for the season as a basis, only the severe reductions in emergence were reflected in reduced yields. Yields at the first date of harvest were, however, much more closely indicative of emergence; in most cases the treated rows produced heavier yields than the untreated ones at this harvesting date. Comparison of emergence data with moisture conditions at the different planting dates and with temperatures prevailing during the germination phase indicated that the emergence correlated fairly well with the temperature but not with the moisture. According to the findings, soil temperature may be considered an important factor in determining the emergence of garden peas. Limited tests with smooth-seeded field pea varieties showed them to be favored by higher temperatures than were garden peas during the germination phase.

**Klornitrobenzol-Forbinderler som Middel mod Kaalbrok, Kartoffelskurv, Kløver-Baegersvamp og "Brune Rødder" paa Tomat** (Chloronitrobenzene for control of club-root, potato scab, clover stemrot, and brown root-rot of tomato), E. GRAM (*Tidsskr. Planteavl*, 49 (1944), No. 1, pp. 118-143, illus. 6; *Eng. abs.*, p. 143).—In control against clubroot (*Plasmodiophora brassicae*), Brassicol (pentachloronitrobenzene), Brassisan (dinitrotrichlorbenzene), and another chloronitrobenzene showed distinct effects. The effects on potato scab (*Actinomyces scabies*) were less pronounced, but promising results were obtained with the first, which exhibited a residual effect on potatoes grown in plots the following year; this preparation plus  $(\text{NH}_4)_2\text{SO}_4$  could be used with advantage

for scab control. Brassicol also reduced the formation of *Rhizoctonia solani* sclerotia on the tubers. Dusting with Brassicol alone or diluted with talc proved effective against clover stem rot (*Sclerotinia trifoliorum*); with a portable rotation duster, one man could treat 1 ha. of a clover seed field in 3 hr. Used as a soil disinfectant in the greenhouse, Brassicol applied just before planting tomatoes prevented to some extent the development of brown root rot; Brassisan was less effective.

**Control of anthracnose on cannery tomatoes—two years' results,** D. M. McLEAN and E. H. BJORNSETH (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 287–293, illus. 1).—*Colletotrichum phomoides* infection is considered the most destructive tomato fruit disease in the more important eastern canning districts; it also causes considerable losses in Indiana, Ohio, and Michigan. The symptoms and host-parasite relations are described. This paper reports primarily on the 1945 experiments in Michigan, the results of which indicate that Fermate may be expected to give considerable control of anthracnose but that it fails to give adequate results against leaf diseases. It was indicated that Zerlate (zinc dimethyl-dithiocarbamate) may be more efficient against both leaf diseases and anthracnose; since it is essential to control leaf diseases as well as fruit rots, the manner in which these two fungicides should best be fitted into a general control program remains to be determined. Different tomato varieties and the same variety planted on different dates do not ripen their fruits during the same periods; that, as well as seasonal variations, suggests that spray schedules should be timed to correspond with the stages of plant growth or fruit development. In general, the first application should be applied not later than 30 days after development of the first blossom cluster or when the fruits of the first cluster are about half to three-fourths full size; others should follow at about 10-day intervals until five treatments have been given.

**Tomato blight control in southwest Virginia,** R. G. HENDERSON (*Virginia Sta. Bul.* 394 (1946), pp. 9, illus. 3).—Early blight, septoria leaf spot, and late blight are extremely destructive on tomatoes nearly every year in this area. Spraying or dusting the foliage and fruits with fixed copper fungicides (e. g., cuprous oxide and tribasic copper sulfate) were found to keep these diseases under control. Tomatoes in the home garden should be dusted or sprayed regularly every year; in commercial plantings they should also be treated if the unit price anticipated is sufficient to justify the expense. The fungicide can be applied more quickly and with greater ease as a dust, a hand-operated crank-type duster being suitable for the home or small commercial planting; but a motor-driven duster or power sprayer better for larger plantings. The dust mixture should contain about 5 percent metallic Cu, with pyrophyllite or talc as the diluent. The spray mixture should be prepared according to the directions on the package; use yellow cuprous oxide at the rate of 1.5 lb. to 100 gal. water and tribasic copper sulfate at 3 lb. to 100 gal. Dust and spray when the wind is not blowing; dusts may be applied with the foliage wet or dry, but the spray should be applied only when it is dry. The first application should be made about 10 to 14 days after setting in the field, with other treatments following at 7- to 10-day intervals; five to seven applications will usually be required for satisfactory control.

**The treatment of little-leaf of deciduous fruit trees,** K. M. WARD (*Queensland Dept. Agr. and Stock, Div. Plant Indus. (Res.) Bul.* 21 (1944), pp. 1–18, illus. 6).—In trials of methods of applying Zn as a corrective, a winter spray consisting of a 5 percent aqueous solution of  $ZnSO_4$  gave satisfactory responses within a few months; little control followed use of a 1 percent

solution. Spring foliage sprays containing up to 2 percent  $\text{ZnSO}_4$  gave little or no immediate benefit; winter sprays not only produced an earlier response but had more lasting effects. Broadcasting and plowing under 5 lb.  $\text{ZnSO}_4$  around an affected tree were followed by beneficial effects in the second and third years thereafter; tree injections proved unsatisfactory. Probably winter spraying and soil treatment in conjunction would be preferable to winter spraying alone in the early treatment of the disorder.

**Boron deficiency in pears—symptoms and control measures**, S. W. FERGUSON and J. A. HOLBECHE (*Agr. Gaz. N. S. Wales*, 57 (1946), No. 5, pp. 241–243, illus. 7).—In the Kentucky district of New South Wales tests have shown that many of the disorders causing serious crop losses in pears were directly due to B deficiency; tree growth was also retarded—in some instances seriously. Borax applied to the soil or as a spray gave complete control, even severely affected trees soon commencing to grow vigorously. The tree and fruit symptoms of B deficiency in pears are described and illustrated.

**Bacterial canker of stone fruit**, F. L. MILLTHORPE and A. E. VINCENT (*Agr. Gaz. N. S. Wales*, 57 (1946), No. 5, pp. 255–257, illus. 9).—Bacterial canker (*Pseudomonas cerasi pruni*) is reported to occur on stone fruits throughout New South Wales, with serious losses on apricot, cherry, nectarine, peach, and plum trees. The symptoms and tentative control measures are discussed.

**Apricot leaf scorch in Utah County**, F. B. WANN (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, pp. 5, 14–16, illus. 2).—In the early summer of 1944 a severe marginal burning of apricot leaves was observed in this county; in advanced stages the appearance suggested a scorching as by fire, hence the name, “leaf scorch.” The effect on the trees was serious. The symptoms are described in detail, the distribution of the disorder in the State is outlined, and the possible causes—atmospheric conditions, mineral nutrient deficiency, rootstock relations, virus infection—are discussed. Though the cause is still undetermined, the most likely explanation appears to be a combination of soil and meteorological conditions.

**Bacterial spot of peach and its behavior in Delaware**, S. L. HOPPERSTEAD and T. F. MANNS (*Delaware Sta. Bul.* 258 (1945), pp. 24, illus. 8).—Data from the experiments and observations here discussed are believed to warrant the following conclusions: The casual organism, *Xanthomonas pruni*, is readily carried to healthy peach stock by buds from infected trees; the organism is readily carried in the buds proper and in the base of the buds during June–August, and it is also present in the lateral buds of peach during the early part of the dormant season; it may overwinter in the lateral buds of peach trees stored in sheds pending spring shipment; infected trees may be freed of infection by growing them under the dry conditions of the greenhouse and subirrigated or they may be grown in arid regions until determinations by culture indicate the organism is absent; a small percentage of terminal buds overwinter *X. pruni* under Delaware field conditions, but the lateral buds do not; and primary infections in the State are largely associated with infected terminal buds. There are 26 references.

**Resolution of strawberry virus complexes by means of the aphid vector *Capitophorus fragariae* Theob.**, I. W. PRENTICE and R. V. HARRIS (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 50–53, illus. 4).—Aphids were fed up to 24 hr. on strawberry plants with mild crinkle, severe crinkle, or yellow edge and then transferred to wild (*Fragaria vesca*) or cultivated (Royal Sovereign variety) strawberry plants. On *F. vesca* the symptoms were chlorotic speckling, leaf distortions, and dwarfing of varying intensity; on Royal Sovereign, scattered inconspicuous diffuse chlorotic spots. The symptoms from all three

infection sources were similar and indistinguishable from those of the mild crinkle of Harris and King; the virus thus selectively transmitted is tentatively concluded to be the mild crinkle virus. It was transmitted after feeding periods of 1 hr. or more and failed usually to persist in the vector for more than 3 hr.

**Summary of chlorosis experiments with grapes at the Southern Great Plains Field Station, Woodward, Okla., L. F. LOCKE. (U. S. D. A.). (*Oklahoma Sta. Bul.* 295 (1946), pp. 23-28).**—On the basis of the experiments reported, mulches are not recommended as a control measure; the manure mulch proved actually harmful. Only  $\text{FeSO}_4$  (copperas) sprays were effective; frequent applications on both grape and spirea reduced the chlorosis most; Zn and Ca sprays—alone or combined—were of no benefit. All chemical treatments of grapes at 0.25 to 2 lb. of chemical applied to the soil failed. Al,  $\text{NH}_4$ , or Mg sulfates were also of no benefit. Commercial  $\text{ZnSO}_4$  at 5 lb. per vine in solution applied to the soil gave only very slight signs of benefit. Iron sulfate gave definite ameliorative results at 5 lb. per vine; quicker results followed application in solution than the same or larger amounts used dry, but the effects lasted a shorter time. Single applications at 5 to 60 lb. per vine in solution controlled the chlorotic condition without injury to the plants. This chemical applied in solution to the soil was also effective for Vanhoutti spirea, but apparently must be used with more caution than for grapes. Soil treatments with  $\text{FeSO}_4$  have also shown benefits on 120 species and varieties of trees and shrubs and numerous annual and perennial flowers.

**A ganoderma root rot of citrus, F. W. BLACKFORD (*Queensland Dept. Agr. and Stock, Div. Plant Indus. (Res.) Bul.* 22 (1944), pp. 19-23, illus. 3).**—The cause of root rot here reported and described was identified as *Ganoderma lucidum*.

**O teste do iôdo na identificação da "tristeza" dos citrus [The iodine test for identifying the tristeza disease of citrus], V. ROSSETTI (*Biológico*, 11 (1945), No. 1, pp. 13-21, illus. 1).**—An account of large-scale confirmatory trials in various localities of the iodine test of Bitancourt previously noted (*E. S. R.*, 92, p. 381).

**Sobre la podredumbre de las raicillas de los citros [On the decay of rootlets of citrus trees] (*La Chacra [Buenos Aires]*, 15 (1945), No. 180, pp. 30-31, illus. 3).**—A note of rootlet rot of citrus trees, also called tristeza, and the relation of nematodes to it.

**A new species of *Sphaceloma* causing scab of plantain (*Plantago*), A. E. JENKINS and A. A. BITANCOURT. (U. S. D. A. et al.). (*Jour. Wash. Acad. Sci.*, 36 (1946), No. 7, pp. 225-227, illus. 1).**—*S. plantaginis* n. sp. on *Plantago* spp. is described and illustrated.

**A previously undescribed fungus causing a leaf spot of bamboo, L. SHANOR (*Mycologia*, 38 (1946), No. 3, pp. 331-333, illus. 3).**—The pycnidial stage of this fungus on leaves of *Arthrostylidium racemiflorum* is described as *Ciliochorella bambusarum* n. sp., and the ascocarpic stage—a hemisphaeriacous fungus—as *Lateropeltis bambusarum* n. gen. and sp. The ascogenous stage is not known to occur except in conjunction with the pycnidial phase.

**Diseases of cultivated guayule and their control, W. A. CAMPBELL and J. T. PRESLEY (*U. S. Dept. Agr. Cir.* 749 (1946), pp. 42, illus. 7).**—The authors obtained information on guayule diseases during 1942-45 from observations on 2,000 acres of nurseries, 30,000 of field plantings, and from greenhouse, laboratory, and field experiments. On most irrigated and nonirrigated well-drained soils losses from disease were unimportant in the production of nursery or field-grown guayule. Serious losses occurred, however, on poorly

drained irrigated soils or on well-drained soils when excessive amounts of water were applied. Careful control of irrigation proved necessary to the avoidance of disease losses on many irrigated plantings. The most important nursery diseases were those caused by *Pythium ultimum*, *Sclerotinia sclerotiorum*, *S. minor*, *Botrytis cinerea*, and *Verticillium albo-atrum*. The disease losses in guayule plantations were due mainly to root rots, the more important of which were due to *Phytophthora drechsleri*, *Phymatotrichum omnivorum*, and an unidentified bacterium. Other fungi pathogenic to guayule were *Sclerotium bataticola*—cause of a crown rot on dry land plantings in Texas during hot dry weather, *S. rolfsii*, *Sclerotinia* spp., and *Diplodia theobromae*—attacking guayule in southern Texas in late summer and fall, and *Puccinia parthenii*—known only from Mexico. Strain 109 in field plantings proved very susceptible to *V. albo-atrum*, strain 405 was resistant, and strain 593—the one most commonly planted—was intermediate in susceptibility.

**Diplodia die-back of guayule** (*Parthenium argentatum* Gray), J. T. PRESLEY. (Miss. Expt. Sta.). (*Phytopathology*, 36 (1946), No. 7, pp. 565–571, illus. 2).—*D. theobromae* caused a severe dieback of a 2-year-old irrigated guayule in southern Texas during late summer and early fall, 1944; younger irrigated shrubs and 2-year-old shrubs on dry-land plantings were not appreciably affected. Inoculation tests revealed that spores in the soil could cause the loss of small seedlings, especially at 80° F. Leaf and twig infections in the greenhouse depended on high humidity for 24 hr. or more and temperatures of 80° to 90°. Hardened plants with old dry leaves proved more susceptible than young succulent plants with active green leaves.

**A curious fungus on Opuntia**, B. O. DODGE (*Bul. Torrey Bot. Club*, 73 (1946), No. 3, pp. 219–223, illus. 2).—*Tretopileus opuntiae* n. gen. and sp.—a fungus of as yet undetermined relationships occurring on pads of *O. ammophila*—is described and illustrated; it was clearly not very destructive to its host.

**The control of narcissus leaf diseases.**—III, *Sclerotinia polyblastis* Greg. on *Narcissus tazetta* var. *Soleil d'Or*, P. H. GREGORY and G. W. GIBSON (*Ann. Appl. Biol.*, 33 (1946), No. 1, pp. 40–45).—In this contribution (E. S. R., 85, p. 370), the author reports that in southwestern England *N. tazetta* grown for the outdoor flower crop is regularly attacked by “narcissus fire” (*S. polyblastis*). A randomized strip test on the variety *Soleil d'Or* begun in 1937, in which half of the plots were sprayed with bordeaux each season, gave data as to the effect of controlling the disease on the number and quality of the flowers produced in 1939–41 and on the weight and grade of bulbs lifted in 1941. There was an average increase of 26 percent in the number of flowers on sprayed plots and a 35 percent increase in weight of bulbs. There was no evidence of any cumulative improvement, because most of the gain in one year appeared to have been immediately expended in increased flower production the following season; the sprayed plots, however, maintained a higher general level throughout. The quality was improved by spraying, mainly by addition to the inflorescence of an average of one extra “bell.” Though not cumulative, there was a residual effect shown by the increased yield of bulbs in 1941 after a season in which only one postflowering spray had been applied. The effect of treatment on the date of flowering (anthesis) was negligible, and its direction depended on the season. In this respect *Soleil d'Or* differs from *Golden Spur*, in which spraying induced a marked retardation of flowering 1938–39.

**Epidemic tree diseases threatening shade trees in Michigan**, F. C. STRONG. (Mich. State Col.). (*Mich. Forestry and Park Assoc. Ann. Mtg.*, 20 (1946),

pp. 7-13).—This paper summarizes the present status of knowledge on the losses caused from, and the present distribution in the United States, hosts, cause, symptoms, vectors, and control of, the Dutch elm disease, phloem necrosis of elms, oak wilt, and maple wilt. Remarks in response to the paper are by H. Chapel (pp. 11-13).

**As galhas pulverulentas das Lauraceas (The powdery galls of the Lauraceae),** A. A. BITANCOURT and V. ROSSUCCI (*Biológico*, 12 (1946), No. 3, pp. 55-62, illus. 3; *Eng. abs.*, p. 61).—In Neotropical forests, trees of several genera of the laurel family (*Nectandra*, *Ocotea*, *Cryptocarya*, etc.) often exhibit in spring and summer galls induced by fungi which have been variously placed among the Peronosporaceae, Melanconiaceae, Basidiomycetes, etc.; their inclusion under the last-named group is believed warranted by their morphological characteristics. In São Paulo the following species causing galls have been observed since 1941: *Drepanoconis larviformis*, causing chalk-white powdery galls on the young sprouts, stems, leaves and pistils or young fruits; *Clinoconidium farinosum*, dark brown powdery galls on young stems; *Clinoconidium* sp., warty galls on the leaves; *Botryoconis saccardoi*, brown galls on the stems; and *D. pallida*, whitish powdery galls on the fruits, and an undescribed fungus of the same group causing a yellowish powdery gall on the stems.

**Effect of mineral nutrition on the vigor and susceptibility to blight of old Japanese chestnut trees,** J. D. DILLER, C. W. WHITTAKER, and M. S. ANDERSON. (U. S. D. A.). (*Phytopathology*, 36 (1946), No 7, pp. 554-556).—Varying fertilizer treatments were applied to 64 50-year-old Japanese chestnut trees, which were later inoculated with isolates of the chestnut blight fungus (*Endothia parasitica*) from Massachusetts and Maryland. No significant effect on shoot growth resulted from applications of K or P; N at the rate of 150 lb. per acre was without effect but 300 lb. increased the shoot growth in 1944, though a second application in 1945 had no significant effect. There was no correlation between shoot growth and trunk diameter, nor was any connection observed between canker size and fertilizer treatments. No significant difference occurred between Massachusetts and Maryland isolates as to the size and total number of cankers produced; the longer established Massachusetts cultures were as virulent as the younger Maryland isolates. Fertilization with K and P a year previous to inoculation increased the incidence of and susceptibility to canker, but this effect was modified in a complicated manner by a N treatment. Field observations made during six growing seasons revealed KCl to be an unfavorable form of potash for chestnuts; the effects noted may have been connected with some toxic effect of the chloride ion.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Pittman-Robertson contributions to forest game restoration and management,** R. M. RUTHERFORD (*Jour. Forestry*, 44 (1946), No. 6, pp. 419-423).—The Federal Aid in Wildlife Restoration Act of September 2, 1937—popularly known as the Pittman-Robertson Act—was designed to provide aid to the States in the restoration of wildlife. This article reviews the program to date, with the conclusion that it has resulted in substantial progress toward better management of forest wildlife and in bringing back vanished species to habitats suitable for them.

**Game (Nova Scotia Dept. Lands and Forests Rpt., 1945, pp. 76-109, illus. 3).**—This is a report on game in Nova Scotia for 1945, including information on moose, deer, beaver, partridge, pheasants, rabbits, bears, muskrats, silver foxes, fur-bearing animals and fur farming, game sanctuaries. statistical

data on licenses, etc., and a paper entitled *This Predator Legend*, by J. B. Abbott (pp. 87-94).

**Pheasants, fox, and quail**, I. O. BUSS (*Wis. Conserv. Bul.*, 11 (1946), No. 4, pp. 8-15, illus. 4).—A low pheasant and high quail population was found on a 9,900-acre Wisconsin area during January-February 1946; these contrasting densities fail to support the allegations that fox depredations caused the 1945 pheasant scarcity. Precipitation and temperature records plotted and averaged for the periods before, during, and soon after most pheasant nests were started show a sharp contrast between the 1942 and 1945 minimum temperatures during the time that most pheasant nests are typically started. If all or most pheasants habitually lay first eggs at random, it is entirely possible that low temperatures such as existed from late April through June (1945) inhibit or even prevent pheasants from laying in nests. Such a temperature threshold could explain the latitudinal limits of all pheasant range. Of 453 bobwhite quail trapped on the area, 56 percent were ♂♂; this distorted sex ratio is similar to the 53 and 58 percent ratios reported for Missouri and the Southeastern States. Of 275 quail trapped and aged during 1946, 84 percent were immature (less than a year old); this high percentage of immature birds is similar to the 77 and 83 percent immature bobwhites found in southern Missouri and reflects successful reproduction during the previous breeding season. Weights of 436 bobwhites trapped in the area during January-February (1946) ranged from 154 to 255 gm. and averaged 200 gm.; this is 14 gm. heavier than bobwhites from Missouri and 35 gm. above those in Georgia.

**Mammals of the northern Great Plains along the International Boundary in Canada**, J. D. SOPER (*Jour. Mammal.*, 27 (1946), No. 2, pp. 127-153, illus. 5).—The author's aim is to give an account of the native mammals inhabiting a relatively broad strip along the International Boundary in Canada from southeastern Manitoba to the foothills of the Rockies. Following notes on the physiography and descriptions of the faunal life zones, local information is presented on the individual species. There are 35 references.

**The carnivores of the San Andres Mountains, New Mexico**, A. F. HALLORAN (*Jour. Mammal.*, 27 (1946), No. 2, pp. 154-161).—Accounts of the individual species are presented following brief descriptive details on the area, a list of localities, and the number of carnivores present. There are 17 references.

**Parasites, diseases, injuries, and anomalies of the Columbian black-tailed deer (*Odocoileus hemionus columbianus* (Richardson)) in British Columbia**, I. M. COWAN (*Canad. Jour. Res.*, 24 (1946), No. 3, Sect. D, pp. 71-103, illus. 29).—The occurrences of parasites, parasitic disease, some nonparasitic diseases, and certain anomalous conditions in this species of deer are outlined. The findings are in two categories, viz, those based on a random sample of 40 wild deer and those based on 25 additional deer examined in their entirety and others in part; 25 species of parasites—8 arthropods and 17 helminths—were recovered. The study did not include bacteria or viruses; the only pathogenic micro-organism identified was *Actinomyces israeli*.

**On the decoying of coyotes**, J. R. ALCORN (*Jour. Mammal.*, 27 (1946), No. 2, pp. 122-126, illus. 1).—A note on the comparative ease with which coyotes may be called up within a few yards of a concealed observer. During August 1944-May 1945, the author decoyed a number of coyotes and a few lynx cats to the vicinity of a blind containing one or two persons by using one or a combination of two of three calls here designated as the "squeak," "howl," and "distress" calls.

**The raccoon, a new host for *Microphallus* sp., with additional notes on *M. ovatus* from turtles**, R. RAUSCH. (Mich. State Col.). (*Jour. Parasitol.*, 32

(1946), No. 2, pp. 208-209).—A brief note on this trematode as a parasite of raccoons.

**Some notes on the life history of the Mexican ground squirrel [*Citellus mexicanus*] in Texas.** R. L. EDWARDS (*Jour. Mammal.*, 27 (1946), No. 2, pp. 105-115, illus. 10).

**Grey lung virus:** An agent pathogenic for mice and other rodents, C. H. ANDREWES and R. E. GLOVER (*Brit. Jour. Expt. Pathol.*, 26 (1945), No. 6, pp. 379-387).—"The two authors of this paper each isolated in the summer of 1944 a mouse-pathogenic virus, one starting with material from a calf pneumonia, the other with some from infantile diarrhea. The two strains seem to be identical and to differ from any virus hitherto described. This 'grey lung' virus may have originated in the normal mouse stock, but subsequent attempts to obtain strains from the normal mice have failed. The virus is strictly pneumotropic, but commonly not fatal, though infective in high dilutions. It produces in the lungs chronic lesions which remain relatively stationary for many months. Suspensions of lungs are infective in high dilutions for at least 9 mo.—the longest period yet tested—after infection of the mice. The virus is contagious for mice running in the same cage as infected ones, but not very highly so. Neither active immunity nor production of antibodies has yet been demonstrated. The virus will produce chronic infection in cotton rats and will infect other rodents, though it is less pathogenic for them. It is relatively stable and will pass a gradocol membrane of A. P. D. [average pore diameter] 450 m $\mu$ . Differences from other mouse-pathogenic agents are discussed."

**Field book of eastern birds.** L. A. HAUSMAN (*New York: G. P. Putnam's Sons*, 1946, pp. 659+, about 500 illus.).—This field book covers the territory roughly east of the Mississippi River and of the west shore of Hudson Bay—i. e., in general, east of the ninetieth meridian.

**The blood parasites of the blue grouse.** C. D. FOWLE (*Science*, 103 (1946), No. 2685, pp. 708-709).—In blood samples from 44 specimens of blue grouse taken in British Columbia, 4 blood parasites were observed, viz, *Trypanosoma*, *Haemoproteus*, *Leucocytozoon*, and *Microfilaria*. The incidence of infestation is tabulated; mixed infections were found in 7 birds. None of the birds seemed to be suffering any ill effects from infestations by any of these parasites.

**A new nematode, *Longistriata caudabullata* n. sp. (Nematoda: Vianaiinae), from the short-tailed shrew (*Blarina brevicauda*),** G. DIKMANS. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 13 (1946), No. 1, pp. 14-16, illus. 1).—This species is here described.

**A preliminary report on farm pond management in Michigan.** P. I. TACK and W. F. MOROSKY (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 294-303).—This report was prompted by the considerable number of inquiries as to the use of commercial fertilizer to increase fish production in farm ponds. On the basis of a 2-yr. (1944-45) study of farm pond management, it is believed that fertilizer of proper composition for the particular body of water will increase the plankton algae, which in turn will increase the insect population—and this is fish food. Careful management of the fish population utilizing the increased food is considered fully as important as using fertilizer to increase the food supply; the number of fish should be kept down to what will insure maximum growth. The fertilizer formula should be determined for each body of water, or at least for water from several areas of the State. Stocking new ponds should be delayed about 6 weeks after the pond is filled or until the vegetation is thoroughly decayed. These are the main tentative conclusions thus far arrived at.

[Notes on insects and insecticides] (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 262-274).—Contributions presented (E. S. R., 95, p. 533) are Some New Insecticides for Potato Insect Control, by G. G. Gyrisko (pp. 262-263) Cornell Univ.; Eradication of Boxwood Leafminer and the Boxwood Psyllid, by L. Pyenson (p. 264); Effect of Various Dust Mixtures on Incidence of the Cabbage Aphid, by G. E. R. Hervey (p. 265) (N. Y. State Expt. Sta.); The Control of Mites on Apple Trees Sprayed With DDT, by W. S. Hough (pp. 266-267, and The Control of the Cowpea Curculio by L. A. Hetrick (pp. 268-269) (both Va. Sta.); Compatibility of DDT and Fungicides on Potatoes, by J. W. Heuberger and L. A. Stearns (pp. 267-268) (Del. Sta.); Individual Comparisons of Grouped Data by Ranking Methods, by F. Wilcoxon (pp. 269-270); Two Industry Problems Caused by Release of DDT, by C. L. Smith (pp. 270-271); DDT and Lead Arsenate Compared for Control of the Pecan Nut Casebearer—1945 Tests, by C. B. Nickels (pp. 272-273) (U. S. D. A.); Sabadilla and DDT To Control the Squash Bug, by R. R. Walton (p. 273) (Okla. Sta.); DDT for Control of a Book Louse, by D. D. Jensen and F. G. Holdaway (p. 274) (Hawaii Sta.); *Hadrobregmus gibbicollis* Infesting Woodwork, by M. H. Hatch (p. 274); and An Early Use of Arsenic as an Insecticide, by J. A. Munro (p. 274) (N. Dak. Agr. Col.).

**Chamber for fumigating plants with methyl bromide: Construction and operation,** L. L. ENGLISH and G. F. TURNIPSEED (*Alabama Sta. Cir.* 93 (1946), pp. 24, illus. 15).—The authors report the practical details for construction and use of a chamber suitable for fumigating plants with methyl bromide. Materials and special equipment costs total about \$200. Lists of plants which have been fumigated using this equipment without injury, partially or completely defoliated but not killed, and injured too seriously are included.

**New formulations of aerosols dispersed by liquefied gases,** E. R. MCGOVAN, J. H. FALES, and L. D. GOODHUE. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 216-219, illus. 1).—Tests of various liquefied-gas aerosol formulas against houseflies and mosquitoes were made in a Peet-Grady chamber; formulas greatly improved in toxicity over the original one were developed by increasing the nonvolatile content and by adding more sesame oil, another synergist (piperonyl cyclohexenone), DDT, benzene hexachloride, and suitable solvents. In small containers, CO<sub>2</sub> proved satisfactory as a propellant.

**Particle-size distribution in liquefied-gas aerosols,** L. D. GOODHUE and R. L. RILEY. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 223-226, illus. 6).—By the method described for determining particle size in liquefied-gas aerosols, the particles are collected on oleophobic slides and measured by projecting them on a calibrated cross-hatched screen. The results in volume percent are plotted as cumulative frequency curves. The particle size of an aerosol increases with the concentration of nonvolatile material in the liquefied gas; the type of nozzle also affects it. Nozzles allowing some drop in pressure and partial ebullition before the liquid is expelled have proved the most efficient. Particle-size distribution curves for some aerosols of different compositions are given.

**The thermal aerosol fog generator for large scale application of DDT and other insecticides,** R. D. GLASGOW and D. L. COLLINS (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 227-235, illus. 24).—Notable among the pending, as yet unsolved, and particularly baffling insect pest control problems are those which will apparently require large-scale or regional coverage with appropriate insecticides; well-known examples have to do with the control of such

pests as blackflies, punkies, mosquitoes, sandflies, and similar noxious insects and of the tick and similar vectors of Rocky Mountain spotted fever. The airplane and the helicopter have been put to effective use in special cases, but both at present have definite limitations. A third mechanism—product of the war effort—is the thermal aerosol fog generator; this is said to have possibilities possessed by no other device in the same degree. During the past season (1945) the authors arranged and participated in a fairly comprehensive series of tests with two of the leading mechanisms of this type. These explorations have demonstrated that the thermal aerosol fog generator unquestionably has promise of unique value in many fields of pest control work and merits careful experimental study by entomologists and plant pathologists. The preliminary report here presented is designed to bring this fact to their attention.

**The effect of DDT on cutaneous sensations in man**, Y.-C. CHIN and C.-H. T'ANT (*Science*, 103 (1946), No. 2632, p. 654).—The results of tests with 32 student volunteers indicated that oil facilitates the penetration of DDT into the skin. The minimum pressure that would arouse the tactile sensation of the skin in contact with the olive oil solution or vaseline mixture of DDT was 1 to 2.5 gm. per square centimeter higher than the control treated with the diluent only.

**The effects of variations in atmospheric pressure upon insects**, W. G. WELLINGTON (*Canad. Jour. Res.*, 24 (1946), No. 3, Sect. D, pp. 51-70).—The author presents a review and analysis of the available literature (78 references) on the effects of pressure changes on insects. Variations in atmospheric pressure are classified briefly, but the effects of pressure changes on insects are considered from the standpoint of their reaction to extremely low, extremely high, and slight variations in pressure. It is concluded that extreme changes exert no direct influence on insects; on the other hand, there is evidence that slightly reduced pressure increases the rates of development and of the various activities, while slightly increased pressure has no apparent influence on these processes. A discussion of the possible role of chordotonal organs in the observed responses of some insects to fluctuating pressure is included, and certain laboratory experiments are suggested as possible aids in quantitative determinations of the effects of varying atmospheric pressure on insects.

**Concealed phases in the metamorphosis of insects**, H. E. HINTON (*Nature [London]*, 157 (1946), No. 3991, pp. 553-553, illus. 1).—The three examples given are believed to show clearly that the conception of certain biological phenomena is fundamentally altered when the instars are defined more accurately than is usually the case. The term "pharate" is proposed to designate the phase of an instar which is enclosed within the cuticle of the previous instar.

**Folic acid in the nutrition of certain insects**, G. FRAENKEL and M. BLEWETT (*Nature [London]*, 157 (1946), No. 3995, p. 697).—Data presented appear to indicate folic acid to be important in the nutrition of certain test insects (Mediterranean flour moth, yellow mealworm).

**Edgegrowth as related to crop yield and insect damage**, G. W. UNDERHILL and O. F. BODENSTEIN (*Virginia Sta. Tech. Bul.* 97 (1946), pp. 18, illus. 3).—Studies were carried out in an 80-acre field bounded on one side by oak woods and certain planted edge-growth areas. The rotation practiced was wheat, red clover and timothy, and corn, the clover and timothy having been seeded prior to the first collections of insects. Collections were made at 4- to 6-week intervals from March to September during the summers of 1942, 1943,

and 1944. Variations occurred in the number of insects collected in selected areas for certain periods in the season and even with some families and related groups of injurious species, but the differences were not consistently tied up with the relation of the stations to the woods or border plantings. In studies at selected stations on hay yields, injury to young and mature corn did not show differences that could be credited to insect injury as related to edge growth.

Few insects were noted on the three varieties of lespedeza used in the edge-row plantings and none appeared of much economic importance except two species of *Alydus*. The authors conclude that lespedeza seems to fit in well for a border crop in this field.

**Index to "The Grasshoppers and Other Orthoptera of Arizona,"** L. P. WEHRLE (*Arizona Sta. Mimeog. Rpt. 81 (1946), pp. 8+*).—This is a supplement to Technical Bulletin 93 (E. S. R., 87, p. 827).

**Grasshoppers and locusts in Western Australia,** C. F. H. JENKINS (*Jour. Dept. Agr. West. Austral., 2. ser., 22 (1945), No. 4, pp. 322-331, illus. 9*).—The small plague grasshopper *Austroicetes cruciata* Sauss.—said to be the most important grasshopper in Western Australia—is discussed in some detail, including a record of outbreaks and methods of control. Other grasshoppers and locusts of importance in the area are taken up more briefly.

**Benzene hexachloride in grasshopper baits,** S. L. ALLMAN (*Agr. Gaz. N. S. Wales, 57 (1946), No. 4, pp. 171-172, 182, illus. 2*).—Localized outbreaks in New South Wales during 1945 are reported for the wingless grasshopper *Phaulacridium vittatum* and the Australian plague grasshopper *Chortoicetes terminifera*. The tests carried out indicated that "666" (benzene hexachloride)-bran baits were readily eaten by both species, would successfully control the first species in a cabbage crop where gross feeding is necessary to cause losses, and would obviously incapacitate a large proportion of a swarm of the second species within an hour of feeding.

**17-year cicada notes for 1945,** F. M. SCHOTT (*Jour. N. Y. Ent. Soc., 54 (1946), No. 2, pp. 167-169*).—Notes for the New Jersey and nearby New York area.

**Two new Nemocera Diptera (Sciaridae and Cecidomyiidae),** W. F. RAPP, JR. (Univ. Ill.). (*Amer. Ent. Soc. Trans., 71 (1945), No. 4, pp. 125-128, illus. 2*).—The two new genera and species—*Niadina jauva* and *Epourenia viva*—are described, and a key to the North American genera of the family Sciaridae is provided.

**Life tables for *Musca vicina* and *Calliphora erythrocephala*,** B. FELDMAN-MUHSAM and H. V. MUHSAM (*Zool. Soc. London Proc., 115 (1946), pts. 3-4, pp. 296-305, illus. 3*).—Life tables for the imagoes of the oriental housefly and the bluebottle fly *C. erythrocephala* Mg. were compiled from specimens kept under controlled conditions; the former were fed on diluted milk and the latter on 10 percent sugar and chicken liver. In *Musca*, the ♀♀ were slightly longer lived than the ♂♂; the reverse was true for the bluebottle fly. The survivorship curves—and more strikingly the death curves—exhibited a relatively high mortality during the early days of imaginal life. For purposes of graduation, the life tables were broken up into two parts and the first—containing the period of "premature imaginal mortality"—fitted by a fifth order parabola and the second by the Gompertz-Makeham formula. For *Musca*, a complete life table—covering all developmental stages—was compiled and compared with the human life table including miscarriages; this revealed a parallelism between portions of the survivorship curves representing respectively the periods of foetus (egg), infancy (larva), youth and puberty (pupa and young imago), and adult man (fertile imago).

A review of the tachinid genera *Siphophyto* and *Coronimya* (Diptera), H. J. REINHARD. (Tex. Expt. Sta.). (*Ent. Soc. Wash. Proc.*, 48 (1946), No. 4, pp. 79-92).—A key to the species and new taxonomy are included.

Undescribed species of crane-flies from the western United States and Canada (Dipt.: Tipulidae), V. C. P. ALEXANDER. (Mass. State Col.). (*Ent. News*, 57 (1946), No. 3, pp. 65-71).—In the present article (E. S. R., 93, p. 739) three new species of *Tipula* are described.

Notes on the occurrence of the Comstock mealybug (*Pseudococcus comstocki* (Kuw.)) at Niagara Falls, Ontario, R. W. SHEPPARD (*Canad. Ent.*, 77 (1945) No. 12, p. 217).

The life-history of *Pachythelia villosella* Ochs. (= *nigricans* Curt.) (Lep.: Psychidae), J. HEATH (*Ent. Mo. Mag.*, 4, ser., 7 (1946), No. 75, pp. 59-63, illus. 8).—Notes are presented on the life history stages and food plants of this bagworm moth in Britain.

Rate of development of milky disease in Japanese beetle populations, J. A. ADAMS and E. H. WHEELER. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 248-254).—Under the climatic conditions at Poughkeepsie, N. Y., the currently used light dosages of standard milky disease spore dust containing *Bacillus popilliae* applied as soil inoculants against the Japanese beetle are known to be slow to act. Higher dosages, at five rates ranging from 10 to 2,000 lb. to the acre, were applied in April on small field plots and the results observed by frequent soil diggings. A small percentage of diseased larvae was found in all the plots within 1 to 6 mo. after treatment; a satisfactory degree of control, however, was achieved only at the highest dosage after 18 mo. The findings indicate that in southern New York raising the dosage of spore dust from 2 to 2,000 lb. to the acre can reduce the time for satisfactory control from about 4 yr. to about 2 yr. The results support the current practice of using standard spore dust at inoculative dosages wherever eventual and permanent reduction of Japanese beetle populations is sought; they do not hold promise for the use of very heavy applications of spore dust to act as substitutes for chemical soil treatment on restricted areas where immediate control may be imperative.

Japanese beetle attractants with special reference to caproic acid and phenyl ethyl butyrate, G. S. LANGFORD and E. N. CORY. (Univ. Md.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 245-247).—During the war several modified bait formulas were offered to conserve geraniol and eugenol. In expanded studies the past summer with 100 selected mixtures, 40 combinations were found with distinct attractiveness—10 of them ranging from 2 to 3 times as effective as the geraniol-eugenol standard. Two chemicals—phenyl ethyl butyrate and caproic acid—proved exceedingly promising as ingredients for baits. As to simplicity and economy, caproic acid 8 parts and phenyl and ethyl butyrate and eugenol (50-50) 2 parts proved one of the most efficient and practical combinations tried, 29 replications catching 2.8 times as many beetles as the geraniol-eugenol standard; other chemicals in limited tests gave outstanding and attractive baits when used in various combinations. The relations of the chemicals in the mixture, the ratio in which they are combined, and the influence of evaporation rate on the effectiveness of attractants are discussed briefly. The results of these experiments represent trends and indicate the relative values of different combinations for practical application.

*Ligyris burmeisteri*, plaga de los cultivos en La Pampa [The beetle *L. burmeisteri* as a pest of cultivated plants in La Pampa, Argentina], J. WILLIAMSON (*Rev. Argentina Agron.*, 18 (1946), No. 1, pp. 56-58).

A new species of *Tillus* from Arizona (Coleoptera: Cleridae), J. N. KNULL (Ohio State Univ.). (*Ohio Jour. Sci.*, 46 (1946), No. 2, p. 72).—*T. patagoniae* n. sp. is described.

Diatomaceous diluents for dusts, N. TURNER. (Conn. [New Haven] Expt. Sta. et al.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 149-158, illus. 7).—Fifteen laboratory samples of diatomaceous diluents for pure ground derris root were studied. Toxicity tests on the bean aphid showed one to be superior to pyrophyllite, two others to approach pyrophyllite, and a fourth to be somewhat less effective but with a steeper dosage-response curve. Attempts to correlate toxicity with derris to the physical data available were unsuccessful, but materials of extremely fine particle size were not the most effective diluents for pure ground derris. Tenacity studies revealed three types of curves, viz, flatter than, parallel with, and steeper than the standard Bancroft clay. Two of the materials of high tenacity proved relatively effective as diluents for derris. Materials for field trials were selected on the basis of their effects on toxicity and tenacity as determined in the above laboratory tests. Field tests with cube on the Mexican bean beetle showed that the materials performed in approximately the same order as in the laboratory, though more in the order of toxicity than of tenacity tests. The more effective materials performed relatively better in comparison with pyrophyllite in the field than in the laboratory. In field tests of cryolite, materials of high tenacity performed well on both beans and cabbage, but less tenacious materials did surprisingly well.

Alfalfa tripping by insects, G. H. VANSELL and F. E. TODD. (Coop. U. S. D. A.). (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, pp. 9-10, illus. 4).—Four groups of bees were found doing a satisfactory job of tripping alfalfa in Utah fields, namely, *Megachile*, *Nomia*, *Apis*, and *Bombus*, (leaf-cutter bees, alkali bees, honeybees, and bumblebees). Under continuous observation maximum numbers of blossoms tripped by a single bee under observation were as follows: Leaf cutter bees 158, honeybees 129, and alkali bees 78. Mention is made of the fact that strong hives of honeybees contain 30,000 to 50,000 individuals but it is not known how many in such a population are active workers. The authors point out that without the beneficial insect pollinators the production of alfalfa seed is almost as hopeless as is the production of sweet cherries and almonds.

El pulgón verde de los cereales del Uruguay (Toxoptera (= Schizaphis) graminum Rondani [The greenbug of cereals in Uruguay], A. SILVEIRA GUIDO and E. CONDE JAHN (*Univ. Repub. [Montevideo]*, *Rev. Facult. Agron.*, No. 41 (1945), pp. 85-86, illus. 15).—This is a general review and study of this aphid, involving the history of the pest, descriptions of its stages, geographical distribution, host plants, life cycle, characteristics of its attacks, and control—biological, chemical, physical, and auxiliary measures.

The reaction of barley varieties to wheat stem sawfly attack, C. W. FARSTAD and A. W. PLATT (*Sci. Agr.*, 26 (1946), No. 5, pp. 216-224).—In recent years growers on the open plains of western Canada have been seeding barley early, as opposed to the former practice of late sowing which exposed the crop to attack by the wheat stem sawfly. Field observations indicated that practically no damage was sustained following early seeding of the Prospect and Newal varieties; in all but one report of severe injury, Hannchen was the variety grown, thus indicating the existence of varietal differences. In tests (1944-45) of nine varieties seeded in replicated single-row plots, significant differences in infestation were established in all the nurseries employed and in cutting in all but one, thus agreeing in general with previous field obser-

vations. From the standpoints of both infestation and cutting, there was a tendency for the varieties to fall in the same order: Trebi was most resistant; Plush, Prospect, and Newal were almost equally so; Hannchen and Rex proved most susceptible. None of the barleys sustained damage to the same extent as adjacent plots of Apex, Marquis, or Thatcher wheat. The amount of damage to the barley varieties differed greatly from station to station, indicating that environal factors influence the degree of injury. It is pointed out that even though the economic damage to susceptible barleys is relatively small, such fields provide reservoirs of infestation menacing to nearby wheat. At present the barley acreage in the sawfly area is now seeded almost entirely to resistant varieties; it is suggested that introduction of susceptible varieties be avoided.

**Effect of calcic and magnesian diluents of calcium arsenate on bean yields,** J. H. HAWKINS. (Maine Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 145-148, illus. 5).—An average increase in yield of 19.2 percent was obtained from bean plots by treatment with dusts containing high magnesian hydrated spray lime, monohydrated copper sulfate, and calcium arsenate as compared with untreated check plots. An average increase in yield of 11.1 percent was obtained from plots receiving high magnesian lime and calcium arsenate as compared with the check plots and an increase of 1.2 percent when treated with high calcic lime, monohydrated copper sulfate, and calcium arsenate. There was an average decrease of 21.9 percent in yield of beans from the plots treated with dusts containing high calcic lime and calcium arsenate as compared with bean yield from untreated check plots.

**Life history and habits of *Strigoderma arboricola*,** J. M. GRAYSON. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 163-167, illus. 1).—During a 2-yr. study on the economic importance, life history, and habits of *S. arboricola* (F.) in eastern Virginia, surveys of peanut fields at digging time revealed only minor injury to the pods attributable to its grubs or to any other species of grubs. A year was required for a single generation; the winter was passed as a third-instar larva in the soil about 7.7 in. deep. The number of days required for the various life stages during 1944 and 1945, respectively, were, for the egg, 8 to 19 with a mean of 13.6 and 8 to 21 with a mean of 13.4; first-instar larva, 13 to 25 with a mean of 16.2 and 12 to 30 with a mean of 16.6; second-instar larva, 12 to 21 with a mean of 15.1 and 10 to 36 with a mean of 17.5; third-instar larva (1944-45), 238 to 292 with a mean of 257.3; prepupa (1945 only), 5 to 20 with a mean of 11.4; and pupa, 9 to 13 with a mean of 11.9 and 15 to 32 with a mean of 24.9. The mean adult longevity was 17 days for the ♀♀ and 16.7 days for the ♂♂; the mean preoviposition period was 12.5 days, and a mean of 26.3 eggs per ♀ were deposited. Neither adults nor grubs were host-specific. Adults were collected from the blossoms of a number of different plants; grubs, from the soil under all principal agricultural crops grown in the peanut-producing area of Virginia. The dates of adult emergence, egg deposition, and time of entering prepupal and pupal stages are discussed. Measurements of major and minor axes of eggs 1 or 2 days and 12 or 18 days in age are given. The soil and air temperatures occurring during the principal periods of growth are shown graphically.

**Summary of results in six States with DDT as a potato insecticide in 1945** (*Amer. Potato Jour.*, 23 (1946), No. 4, pp. 135-150).—In order to assemble the results of research on DDT, various investigators were invited to submit brief summaries of their work; the reports from trials in six States are here included (Conn. [New Haven] Sta., by N. Turner; Nebr. Sta., by R. E. Hill;

N. J. Stas., by J. C. Campbell and B. B. Pepper; Cornell Univ., by W. A. Rawlins; Ohio Sta., by J. P. Slesman and J. D. Wilson; and Pa. State Col., by J. O. Pepper). Although there was a general agreement on the potentialities of DDT for potato insect control, its place in the spray and dust program "will be secured only after further trial at the hands of investigators and potato growers."

**Control of aphids on potatoes in northeastern Maine,** T. E. BRONSON, F. F. SMITH, and G. W. SIMPSON. (U. S. D. A. coop. Maine Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 189-194).—In field tests in northeastern Maine designed to study the effectiveness of various insecticides against aphids on potatoes, when used with fungicides for controlling late blight, DDT applied as an emulsion, an aerosol, a dust mixture, or a suspension proved effective for reducing populations of the buckthorn aphid *Aphis abbreviata* Patch, the green peach aphid, potato aphid, and the foxglove aphid *Myzus pseudosolani* (Theob.) and increasing potato yields. Although there was a tendency for the dust mixture to be more effective than the sprays and the aerosol, greater quantities of DDT per acre were used in the dust mixture and suspension than in the emulsions and aerosol. Tractor-mounted sprayers applying 100 gal. per acre reduced the aphids more satisfactorily than did traction sprayers delivering 65 to 75 gal. per acre. When a four-nozzle sprayer equipped with vine lifters was used, the aphid kill was slightly greater than that obtained with a standard three-nozzle sprayer; use of a concentrated spray applicator resulted in poor control. All DDT treatments were highly effective against the Colorado potato beetle and potato flea beetle. All treated plots remained green much later in the season, owing to flea beetle control as well as to reduction in aphid populations. Viruliferous dispersal forms of winged aphids were attracted to the green treated foliage and resulted in increasing the percentages of leaf roll in harvested tubers. A zinc nicotinyl fluosilicate dust and a nicotine sulfate spray were effective aphicides. A derris spray proved inferior to DDT. A benzene hexachloride dust mixture was very effective against both aphids and flea beetles.

**DDT to control potato aphids,** G. G. GYRISKO, G. P. WENE, and W. A. RAWLINS. (Cornell Univ.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 205-208).—The green peach and potato aphids are important pests in New York's potato-producing areas. Field tests during the past season on Long Island and in western New York revealed DDT to be a better aphicide than such standard materials as rotenone, nicotine, and the thiocyanates. Except for nicotine fumigation, DDT reduced populations more than the other insecticides tried. The residual effectiveness of DDT was not as pronounced for the potato aphid as it was for the green peach aphid; populations of the former recovered or built up faster between applications than did the latter, perhaps due to a difference in the portion of the plant infested by the two species. The potato aphid is found chiefly on the rapidly growing terminals; the green peach aphid on the lower levels where it is more likely to be in contact with DDT deposits. In comparisons of several concentrations of dust, spray powder, and emulsifiable solution, aphid control and tuber yield increased with each increment of DDT used. The findings suggest that at least 2 lb. of DDT per acre as spray powder or dust are needed in each application during the infestation period. Frequent treatments are necessary to keep populations at a reasonably low level; this proved more important for the potato aphid than for the green peach aphid.

**Susceptibility of Green Mountain and Irish Cobbler commercial strains to stem-end browning,** A. F. ROSS. (Maine Expt. Sta.). (*Amer. Potato Jour.*,

23 (1946), No. 6, pp. 219-234, illus. 1).—Different lots of Green Mountain potatoes vary greatly in susceptibility to stem-end browning; these differences were found to be inherited and not due to differences in the way the seed tubers had been handled. The behavior of each lot was consistent from field to field and year to year. The data obtained revealed two degrees of susceptibility in this variety. In general, the susceptible type or strain produced two to seven times as much browning as the more resistant one, depending on environal conditions. Tuber lines selected from either type were no more or no less susceptible than the original unselected lot. Only in the case of those lots which were mixtures of susceptible and resistant strains did tubers showing the trouble produce more stem-end browning when planted than tubers which were normal in appearance selected from the same lot. All Irish 'Cobbler' lots were highly and equally susceptible.

**Controlling soybean insects.** C. F. SMITH (*Res. and Farming* [North Carolina Sta.], 4 (1946), *Prog. Rpt. 3*, pp. 7, 9, illus. 1).—In North Carolina the most injurious soybean pests are the velvetbean caterpillar, green clover worm, native bean beetle, Mexican bean beetle, corn earworm, and blister beetles. Native bean beetles and Mexican bean beetles do not often cause damage severe enough to justify treatment; blister beetles may be controlled by poison dusts; while leaf worms and corn earworms may be controlled with dusts of cryolite or combinations of cryolite and DDT.

**The influence of cover crops on wireworm injury to tobacco.** D. E. GREENWOOD (*Connecticut* [New Haven] Sta. Bul. 493 (1946), pp. 14-16).—A discussion is given of the value of a rye winter cover crop for reducing damage by wireworm to potatoes. Although it is not suggested that the wireworms are reduced in numbers, the method has been successful because they finish their early season feeding phase on rye roots and do not feed further on tobacco plants when they are set out.

**Seed pitting of the lima bean by *Lygus* bugs in California.** K. F. BAKER and W. C. SNYDER. (Univ. Calif.). (*Science*, 103 (1946), No. 2678, pp. 500-501).—According to this preliminary report, the experimental results establish the fact that the toxic feeding of *Lygus* bugs is responsible for a seed spotting and pitting in the California lima bean crop, as well as for some of the dropping of blossoms and pods. It is believed possible that other insects also may be involved.

**DDT and other new insecticides for control of cauliflower worms on Long Island.** H. C. HUCKETT. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 184-188).—As applied to cauliflower seedbeds for control of the green peach aphid and the onion thrips, dusts with 2, 1, and less than 1 percent DDT tended to be slightly more effective than a cube dust of 0.5 percent rotenone content; a dust containing 2 percent of the DDT analog DDD was slightly less effective. Sprays containing DDT in solution-emulsion form at 0.025 and 0.0125 percent DDT proved fully as effective as those containing a suspension of cube powder at 0.025 percent rotenone. Nearly comparable results were obtained with a spray containing a suspension of DDT in powder form at 0.05 percent DDT; at greater dilutions, results were less satisfactory.

DDT dusts and sprays were also applied to the fall crop of cauliflower for control of the imported cabbageworm, cabbage looper, and diamondback moth in comparison with treatments containing pyrethrum, cube, sabadilla, and Ryanex powders respectively, as well as with a dust containing DDD. Treatments were given three times during August 8-September 24 at intervals averaging slightly longer than 3 weeks. In these tests DDT dusts

ranging in strength from less than 1 to 3 percent DDT were highly effective; a dust containing 2 percent DDD was slightly less so. The remaining dust mixtures—containing such insecticides as pyrethrum, cube root, sabadilla seed, and Ryanex, were significantly less satisfactory, probably due chiefly to the extended intervals between applications. Despite this handicap, plots dusted with a mixture containing 20 percent sabadilla powder gave evidence of promising results. DDT sprays were also effective for worm control; they consisted of suspensions of a wettable powder containing 25 percent DDT and of mixtures of an oil emulsion possessing 25 percent DDT in solution. Sprays containing 1.5 or 3 lb. of the above powder in 100 gal. water (0.047 and 0.094 percent DDT respectively) and 1 pt. of the emulsion in 100 gal. water (about 0.0312 percent DDT) were slightly more effective than those of lower DDT content. These results are of particular interest locally in that heretofore sprays containing suspensions of pyrethrum or rotenone-containing powders have not been effective for worm control on cauliflower.

**Insecticidal aerosols for pea aphid control—second report, L. P. DITMAN, L. D. GOODHUE, F. F. SMITH, and G. BURKHARDT.** (Md. Expt. Sta. coop. U. S. D. A.) (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 199–204, illus. 1).—In further work (E. S. R., 93, p. 745), aerosols containing 5 percent of DDT in various formulas were applied to about 100 acres of Alaska and wrinkled pea varieties with a dispenser designed for commercial use and mounted on a jeep. Treatments with 0.5 lb. DDT per acre at speeds of 3 to 5 miles per hour were more uniformly effective than higher speeds and lower dosages. Nozzles with an output of 3 gal. per hour were comparable to the previously used 2-gal. per hour nozzles. Successful applications were made during varying weather conditions, including temperatures of 54° to 84° F., wind velocities up to 20 miles per hour, and in both sunshine and rain. Treatments resulted in 97 to 99 percent reduction of the aphids and in yield increases of 10 to 67 percent where infestations were heavy. Better aphid control and greater increases in yield were obtained on Alaska than on wrinkled peas; this may have been due in part to differences in vigor of infestation. Nozzle stoppage due to corrosion particles or formation of crystals was largely corrected by including a methylated naphthalene in the solution, adding 1 percent of propylene oxide to combine with any free acids, and installing a filter in the line.

**DDT preparations for control of the pea aphid, L. P. DITMAN.** (Md. Expt. Sta., U. S. D. A., et al.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 219–222).—In the experimental plots and commercial applications here described, dry-mixed DDT dust and suspensions of DDT in water failed to give satisfactory control of the pea aphid. All of the various DDT emulsion sprays tried gave excellent kills, but some formulations caused serious plant injury—attributed to the direct action of the solvent or the emulsifier on the plant and to excessive amounts of one or the other of these ingredients. Emulsions of DDT in xylene, ethylene dichloride, and the aliphatic petroleum oils—in which minimum amounts of solvent and emulsifier were used—were apparently the safest of the treatments on the foliage. In limited phytotoxicity tests, Velsicol AR-60 appeared to be a satisfactory solvent; Triton X-100 was the most satisfactory emulsifier tested. A safe formula for spraying apparently consists of xylene or ethylene dichloride 390 cc., DDT 227 gm., and Triton X-100 20 cc.; this suffices for 1 acre of peas and should be diluted with enough water to make the amount of finished spray being applied per acre. DDT at 0.5 lb. per acre in a water emulsion appears to be ample for pea aphid control, and in tests reported was superior to the proprietary

rotenone emulsion Tubicide at twice its recommended concentration and to the standard spray of ground derris root.

**DDT as a control for the pea aphid, H. GLASGOW.** (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 195-199, illus. 3).—Though much progress has been made over a 10-yr. period in pea aphid control, the methods and materials now commonly available still leave much to be desired. With this situation in mind, DDT was given a trial during the past season in a number of dust formulations, as well as in concentrated and conventional type sprays. The experience thus far is said to indicate that DDT in either dust or spray form has real possibilities for use against this pest.

**An evaluation of various sprays to control immature squash bugs, T. C. WATKINS.** (Cornell Univ.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 255-261, illus. 1).—The results of numerous laboratory tests of 26 sprays against squash bug eggs, 21 against newly hatched nymphs, 10 against nymphs at least 21 days old, and 1 spray against adults are presented; none of the materials gave evidence of real effectiveness as ovicides, but several—notably those containing pyrethrum—gave high kills of young nymphs. On further testing against older nymphs the same materials failed to kill any high percentages of them. Three formulations of DDT sprays were tested, but only the one made from an oil base containing 5 percent DDT proved effective against active stages. It is suggested that for further laboratory or field testing an emulsible oil be used which contains a much greater amount of DDT in order to apply a large enough dosage to kill older nymphs while at the same time reducing the amount of oil to a concentration not injurious to foliage. Two copper fungicides included in the series showed no appreciable toxicity to either eggs or active stages.

**Tomato fruitworm control, W. E. PEAY.** (Coop. U. S. D. A.). (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, pp. 3-4, illus. 3).—An account relating to past work on the tomato fruitworm, habits of this insect, various problems involved in Utah, and a discussion showing how accurate predictions of infestations can aid in control operations. The yellow striped armyworm, which was involved in damage to tomatoes in 1944 and 1945, is also discussed.

**Differences in the life history of codling moth, (*Carpocapsa pomonella* (L.)) attacking pear and apple, T. ARMSTRONG** (*Canad. Ent.*, 77 (1945) No. 12, pp. 231-233, illus. 1).—In a pear orchard on the Niagara Peninsula more or less isolated from other apples and pears, the codling moth strain present appeared to be mainly single-brooded, the moths emerging from overwintered larvae 2 to 3 weeks later than those from comparable apple orchards, and therefore too late to allow more than a very small second brood. If the majority of the spring-brood adults appeared from mid to late June in the pear as in apple orchards, the larvae hatching from the eggs of these moths would find fruits very difficult to enter. It is believed that over a period of time in the past, a high percentage of the early-appearing larvae were unable to make entry into these hard fruits and consequently perished, later appearing larvae—finding more mature and softer fruits which were more easily entered—being able to survive.

**Codling moth control with DDT, G. M. LIST and J. H. NEWTON.** (Coop. U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.]*, 8 (1946), No. 3, pp. 9-12, illus. 1).—Results showed that sprays containing DDT resulted in a smaller percentage of wormy fruit, but must be applied with additional materials if mites are to be controlled. Four different spray programs are suggested.

**DDT for codling moth control in western New York in 1945, S. W. HARMAN.** (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 208-210).—For the second successive year DDT sprays are reported as superior to lead arsenate for combatting the codling moth in western New York; they have been used with apparent safety on both fruit and foliage. Analyses for spray residue on treated fruit indicate that it should not be difficult to keep within tolerance limitations, even after use of a full schedule of DDT in cover sprays. It is possible that trouble with the European red mite may be encountered in the future, but thus far it has not developed to problem proportions as a result of using DDT sprays.

**Use of DDT against codling moth on apples and pears requires caution, A. B. LEMMON** (*Blue Anchor*, 23 (1946), No. 2, pp. 22, 23).—Experiments of 1945 indicated DDT to show great promise for codling moth control on pears and apples, but at present there is no known satisfactory method of removing the residue after harvesting. No significant amounts should therefore be applied on varieties destined for sale as fresh fruits; use of DDT should be restricted to early sprays or to fruits intended solely for processing after removal of the skins.

**Influence of some spray ingredients and dosage of lead arsenate on effectiveness of lead arsenate sprays for codling moth control, W. S. HOUGH** (*Virginia Sta. Bul.* 388 (1946), pp. 11, illus. 3).—Results from evaluating stickers, spreaders, and adjuvants over a 3-yr. period indicated that some materials increased effectiveness of lead arsenate sprays for codling moth control. Data obtained did not show that correctives increased or decreased efficiency of lead arsenate, excepting that the use of 10 lb. of lime per 100 gal. resulted in increased codling moth damage. Where lime-sulfur was used in sprays containing lead arsenate, percentage of fruits injured by codling moth averaged three times greater. Applications of 2, 3, and 4 lb. of lead arsenate were used from 1943 to 1945, inclusive, to observe the relation of dosage to codling moth control, and the reduction in stings was marked in going from a dosage of 3 to 4 lb. When dosage was reduced from 3 to 2 lb. in 1943 and 1944, 2 years favorable for codling moth, a larger proportion of wormy apples resulted.

**DDT and Ryanex to control oriental fruit moth: Their effect upon parasite populations, E. H. WHEELER and A. A. LA PLANTE, JR.** (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 211-215, illus. 2).—DDT and Ryanex were compared with each other, with natural parasitism, and with areas where additional parasites were released for controlling the oriental fruit moth in peaches. Their effect on both twig- and fruit-infesting larval populations and on parasite populations were included in the study. Four sprays of DDT at 1 lb. actual toxicant to 100 gal. applied at 3-week intervals greatly reduced the number of twig-infesting larvae and also the rate of parasitism; Ryanex had a comparable effect, but for a shorter period. The DDT provided superior protection to the fruit. Ryanex failed to give the residual action of DDT but should provide protection if used at shorter intervals. No injury to foliage or fruit was observed, but an infestation of red spider mite appeared late in the season in the DDT blocks.

**Peachtree borer control in Delaware, P. L. RICE and D. MACCREARY** (*Delaware Sta. Bul.* 261 (1946), pp. 21, illus. 3).—During a 3-yr. period the station conducted a study to establish the safety of ethylene dichloride emulsion for peachtree borer control in comparison with paradichlorobenzene and a commercial preparation consisting of paradichlorobenzene dissolved in a miscible oil. Treatments were applied in seven orchards containing three com-

mon peach varieties and to trees 3 yr. old. Surviving borers were counted and observations made on injury from insecticides and increases in trunk diameters of trees. These insecticides did not prove injurious and did not retard tree growth. Paradichlorobenzene gave 88.3 percent control, ethylene dichloride 97.1, and the commercial preparation 94.1 percent. Results confirmed previous findings that ethylene dichloride can be used effectively later in the fall than paradichlorobenzene. The study also indicates that paradichlorobenzene dissolved in oil or other similar formulations are more effective at lower temperatures than paradichlorobenzene.

**Some insects that cause cat-facing and dimpling of peaches in Virginia,** A. M. WOODSIDE (*Virginia Sta. Bul.* 389 (1946), pp. 15, illus. 17).—Heavy losses in peaches have occurred in Virginia as a result of cat-facing and dimpling of fruits caused by the feeding of insects. Studies showed that *Euschistus tristigmus*, the tarnished plant bug, and the plum curculio are the main causes of cat-facing, while the green stinkbug is largely responsible for dimpling. Insects causing these injuries feed on plants other than peach, and the presence of such hosts usually results in an infestation of the insects on peach. Clean culture, and avoidance of cover crops such as clovers, vetch, and alfalfa, are suggested as possible methods for reducing damage. Soybeans and cowpeas should be discontinued as cover crops when injury occurs. Since the green stinkbug feeds on black locust, elderberry, honeylocust, blackhaw, and wild grape, removal of these from or near orchards is recommended. Plum curculio also damages peaches, but peach growers usually keep this insect in check.

**Cat-facing and dimpling in peaches,** A. M. WOODSIDE. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 153-161, illus. 4).—Virginia peach growers have suffered losses from these insect-feeding effects on the fruits. Cat-facing results from attacks of insects when the fruits are small and may be caused by the plum curculio and the tarnished plant bug. Most of it in Virginia orchards seems to be caused by three species of stinkbugs (*Euschistus*); the overwintered adults enter the orchards in April and feed on the young fruits. Dimpling is usually caused by the green stinkbug in midsummer.

**Life history studies of *Euschistus servus* and *E. tristigmus*,** A. M. WOODSIDE. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 161-163).—Life histories of the stinkbugs *E. servus* (Say) and *E. tristigmus* (Say) were studied in cages on peach trees and in the insectary; some observations were also made on the life history of *E. variolarius* (Pal. de B.) in the orchard. *E. servus* and *E. tristigmus* produced two generations per year; *E. variolarius* seems to have but one. All three were reared on peach, though it is not an entirely satisfactory host. Many of the bugs were collected from common mullein.

**DDT on peaches: Three years' field experiments,** B. F. DRIGGERS. (N. J. Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 181-183).—Three yr. of orchard spray tests with DDT at the rate of 1 lb. to 100 gal. water on peaches gave a high degree of control of oriental fruit moth larvae attacking the fruit. One application timed to control the late broods of larvae gave effective control on varieties harvested 3 to 6 weeks after treatment. European red mite built up in large numbers following the DDT sprays and caused heavy defoliation in 2 out of the 3 yr.

**The grapeleaf skeletonizer in California,** H. M. ARMITAGE. (U. S. D. A.). (*Blue Anchor*, 23 (1946), No. 2, pp. 6, 25-32, illus. 1).—The western grape skeletonizer is reported from California, where its spread is said to be gain-

ing momentum each year in both wild and cultivated grapes, along with annual outbreaks of increasing intensity both as to individual properties and to areas. There is strong evidence that it is an introduced species insofar as this State is concerned, and that it is the result of a very recent carry-in by man. The occurrence of the pest is said to be still sufficiently restricted to make its attempted eradication—even though difficult—practical from the physical and economic standpoints. Surveys and preliminary eradication trials have been made. It is believed that eradication could be best accomplished by removal of all wild grapes and abandoned vineyards, combined with a program of attrition on cultivated vines, using annual applications of a poison dust as was tried in 1945 with cryolite 50 at the rate of 25 lb. per acre in June, 15 lb. in July-August, and 15 lb. in September wherever live larvae were still found.

**Use of DDT to control the little fire ant, M. R. OSBURN and N. STAHLER.** (U. S. D. A.). (*Citrus Indus.*, 27 (1946), No. 6, pp. 3, 7, 11).—This serious pest to citrus grove workers in some sections along the eastern coast of Florida may be controlled by DDT, according to early results of tests so far outstanding as to justify preliminary information concerning its use. A given quantity of technical DDT in fuel oil applied as an emulsion appeared to be more effective than by other methods tried. The preferred formulation consists of 0.25 to 1 lb. technical DDT, 1 gal. fuel oil, and 1.3 fluid oz. glyceryl oleate, plus water to make 100 gal. Other formulations for dusts and sprays which have given satisfactory results are presented. No injury to treated grapefruit trees has been observed.

**The European chafer *Amphimallon majalis* and its control in lawns, F. L. GAMBRELL.** (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 168-173, illus. 1).—*A. majalis* Raz. was first observed in North America in 1940 and has become established over an area of about 150 sq. miles in western New York; in a rather limited area, serious damage was observed in turf of lawns, golf courses, parks, and cemeteries, as well as to pasture grasses and wheat fields. For the most part, this pest has a 1-yr. life cycle and causes injuries very similar to those of the Japanese beetle and native species of white grubs. Lead arsenate has been applied at rates of from 250 to 1,500 lb. per acre, calcium arsenate at 500, dusting sulfur and micronized sulfur at 1,000, and DDT emulsions and suspensions at 15, 30, 50, and 200 lb. per acre. Dosages of 250 lb. of lead arsenate per acre proved inadequate for grubproofing the turf; 500 lb. per acre afforded commercial protection for 2 to 4 yr., but 1,000 to 1,500 lb. gave excellent protection and lasted for 4 yr. DDT applied to turf as a suspension at the rate of 30 and 50 lb. per acre appeared promising for larval control; in limited tests 30 lb. per acre proved as effective as 500 lb. of lead arsenate. Likewise, DDT effected a much higher percentage of grub reduction within 2 mo. than did 500 lb. of lead arsenate in the first year following application. A DDT spray suspension applied on trees at the rate of 8 oz. in 100 gal. water knocked down and killed adults coming to rest in treated trees for several days after treatment, but was less effective than the same material at 5 lb. in 100 gal. Even at the higher concentration some gravid ♀♀ deposited eggs before dying. The effect of such treatment on grub reduction was not determined.

***Crioceris lili* Scop. (Col.: Chrysomelidae) in Flintshire, K. J. COGHILL** (*Ent. Mo. Mag.*, 4. ser., 7 (1946), No. 75, p. 51).—A brief note on damage by this beetle to *Alstroemeria violacea* and various species of lily in Britain.

**Factors in the natural resistance of woods to termite attack, G. N. WOLCOTT.** (P. R. Univ. Expt. Sta.). (*U. S. Dept. Agr., Forest Serv., Caribbean For-*

*ester*, 7 (1946), No. 2, pp. 121-134, 139-149; *Span. abs.*, pp. 139-149).—It is pointed out that woods high in cellulose have a high food value for termites and that those with a high lignin content are avoided. In the species of wood tested the sapwood is more acceptable while heartwood is largely not attacked. Other factors in wood such as catechin, hematoxylin, fustic, morin, saponin, etc., may retard or prevent termite attack. Wood of many tropical trees, a few semitropical trees, and Osage-orange and southern cypress of the temperate zone are resistant to attack by termites. Natural resistance in coniferous woods is apparently due to their natural impregnation with specific resinous gums.

**Roach powder: DDT formula improved by the addition of "Lethane A-70" to improve knockdown**—a discussion of combination roach powders, R. B. SCHWITZGEBEL (*Soap and Sanit. Chem.*, 22 (1946), No. 5, pp. 131-133, *illus.* 1).

**DDT thermal aerosol fogs to control clothes moths in a wool storage warehouse**, D. L. COLLINS and R. D. GLASGOW (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 241-245, *illus.* 2).—From experimental tests in a five-floor warehouse containing raw wool, it appears that an insecticidal aerosol fog may have special advantages indoors for some types of insect control work; the aerosol fog seems less subject to loss of concentration through leakage than in fumigations with a gaseous insecticide. Since all the DDT-bearing thermal fogs used in these tests killed practically all of the adult moths in a heavy warehouse infestation, nothing is left on which to base comparisons or an appraisal of the value of added pyrethrins. Not only were the adult moths virtually all killed by the DDT aerosol fog, but even the little DDT that was used appeared to have left residual deposits which killed at least some of the subsequently emerging moths, as well as some of the surviving larvae. Moths and larvae exposed in cages were also killed. The possibility that this technic may provide a much more economical control than any of the older warehouse methods is deemed very promising; use of the method in food storage warehouses would, however, be quite inadvisable. Smallness of particle size is apparently an important factor in governing the persistence and searching properties of these fogs indoors. Plans for following up these preliminary results are under way.

**Experiments with DDT in filter fly control**, W. C. BROTHERS (*Sewage Works Jour.*, 18 (1946), No. 2, pp. 181-207, *illus.* 6).—This paper is an attempt to contribute from an entomological standpoint to the knowledge of those members of the insect family Psychodidae which are involved in the processes occurring in a sewage trickling filter. Matters considered are the properties of DDT, characteristics of filter flies, the experimental criteria followed, larval control experiments on selected filter areas and those involving an entire filter area, and adult fly control by sprayed residues on resting surfaces, the results of which are taken up in great detail. Effective control was obtained when a DDT dosage of 0.5 p. p. m. was applied in a batch dose and the sewage flow so diverted as to allow the DDT to trickle slowly through the filter for 30 min. Larval reductions of 95.4 and 44.3 percent were obtained in the two tests, with an 80 percent over-all decrease at a depth of 2 ft. in the filter bed. Within 20 min. after treatment a very substantial initial kill had been obtained on both adults and larvae of *Psychoda alternata* Say and *Telmatoctopus albipunctatus* (Will.). This dosage with its 30-min. contact period gave effective larval control for about 30 days, and resulted in such reduction of the adult flies as to warrant consideration as an adequate control measure. A general discussion of the findings and suggestions on preparing and applying the DDT emulsion are presented.

**Control of trickling filter flies with DDT**, J. A. CAROLLO (*Sewage Works Jour.*, 18 (1946), No. 2, pp. 208-211).—DDT applied at the rate of 0.2 lb. per acre under laboratory conditions was found to kill adult psychodid flies; at 1 to 5 p. p. m. it killed the larvae; but at 30 lb. per acre over the surface of a sewage trickling filter it did not materially reduce the psychodid larval population. DDT applied as a Triton-xylene emulsion to the influent of a trickling filter controlled the larvae and therefore the adults also. The successful amount based on the total 24-hr. flow was 1 p. p. m., but the concentration applied was actually greater at the beginning of each dosing cycle.

**Acarianos infestadores de culturas de cogumelos: Biologia, classificação, métodos de combate** [Mites infesting fungus cultures: Biology, classification, and methods of control], A. E. AREA LEO, M. T. DE MELLO, and V. MAYOR (*Mem. Inst. Oswaldo Cruz*, 42 (1945), No. 3, pp. 559-608, illus. 16; *Eng. abs.*, pp. 604-605).—The characteristics of mite-infested cultures are described in detail. The study included the morphology, development, and habits of the mites found infesting the culture collections of the Instituto Oswaldo Cruz—tentatively assigned to *Tyroglyphus longior* and *Tarsonemus floricolus*. As a result of tests with various chemicals, the authors recommend the use of kerosene either to kill the mites or to prevent new infestations; it should be dropped on the cotton plugs of the culture tubes and applied abundantly to supports, tables, cupboards, etc., and petri dishes should be placed on filter paper soaked in kerosene. The review of the literature involves 31 references.

**La vegetación acuática y la cría de los mosquitos** [Aquatic vegetation and the breeding of mosquitoes], R. MARGALEF LOPEZ (*Euchides*, 5 (1945), No. 51-52, pp. 318-319, illus. 1).

**The larva and male of *Aedes (Skusea) amesii* (Ludlow) (Diptera: Culicidae)**, H. HOOGSTRAAL and R. W. CHAMBERLAIN (*Ent. Soc. Wash. Proc.*, 48 (1946), No. 5, pp. 125-131, illus. 2).—Descriptions and illustrations of the ♂ and the larva of this oriental mosquito are presented, along with the synonymy and other pertinent notes.

**Three new species of *Aedes* from Netherlands New Guinea**, W. V. KING and H. HOOGSTRAAL (*Ent. Soc. Wash. Proc.*, 48 (1946), No. 4, pp. 95-106, illus. 3).—All of these new species of mosquitoes are believed to be uncommon in the area.

**Studies in laboratory rearing of *Anopheles quadrimaculatus* Say**, R. L. PEFFLY, R. H. DAVIDSON, and H. A. WATERS. (Ohio State Univ.). (*Ohio Jour. Sci.*, 46 (1946), No. 2, pp. 65-70, illus. 2).—Since a constant supply of healthy vigorous adult mosquitoes was needed in various studies of insect repellents, laboratory rearing was initiated; no difficulty was encountered with the yellow fever mosquito, but the rearing of the common malaria mosquito gave considerable trouble. This paper presents several modifications in previous technics which have resulted in greater success.

**The punctulatus complex of *Anopheles* (Diptera: Culicidae)**, L. E. ROZEBOOM and K. L. KNIGHT (*Jour. Parasitol.*, 32 (1946), No. 2, pp. 95-131, illus. 44).—Morphological studies were made of the larvae, pupae, and adult ♀♀ of *A. punctulatus* Dönitz, *A. koliensis* Owen, and *A. farauti* Lav. from the New Hebrides, Solomon Islands, Dutch New Guinea, and the Moluccas. The material consisted of larval, pupal, and adult specimens collected as larvae from natural breeding places and of laboratory-reared progeny from individual ♀♀. The detailed results are presented.

**On the adult bionomics of some Indian anophelines, with special reference to malaria control by pyrethrum-spraying**, R. SENIOR WHITE, A. R. GHOSH, and V. V. RAO (*Jour. Malaria Inst. India*, 6 (1945), No. 2, pp. 129-215, illus.

3).—The Indian literature (46 references) on the spray-killing of adult mosquitoes with pyrethrum insecticides is reviewed; published results indicate that spraying has been much more successful where *Anopheles culicifacies* was the malaria vector than where it was *A. minimus*. The latter was found to take up to 24 hr. longer to complete the gonotrophic cycle than *A. fluviatilis*. Infection rates as found in earlier work are retabulated, and the anthropophilic indexes of 1,832 specimens of 6 species—as found in houses, cattle sheds, and empty shelters—are set forth and discussed. Experiments with stained specimens are described, and a fallacy liable to occur with dry powder stains is discussed; some data on longevity arising from these experiments are also given. There was a very high percentage of survival for over 12 days in cold weather for *A. fluviatilis*, *A. minimus*, and *A. jeyporiensis*. The composition of the population of 8 species, their numbers, and wing and abdominal stage percentages as found in buildings of various constructions—with and without the attraction of blood—are discussed.

The findings indicate that while *A. culicifacies* remains in human dwellings after feeding and until digestion is nearly complete, the vectors of the *A. fluviatilis* group leave the feeding point when the cycle is only half completed and are thus vulnerable to spray-killing for only one daylight period in each cycle. The monthly proportions of the annual total production in 8 species are tabulated, and the validity of the deductions as to age—drawn from wing state—is shown to be very doubtful. A method of moving averages to bring out true fluctuations in numbers is applied to 3 species, and the results are discussed. Data on night catches in sprayed and unsprayed rooms are presented: In *A. fluviatilis* the entrance was highest after midnight, strongly suggesting that the spraying causes a repulsion to entering rooms and so is a useful effect. Experiments with a mosquito trap confirmed the entrance-repellent effect of pyrethrum spraying. Pyrethrum is shown to have different degrees of effect on the numbers of various species, the *A. funestus* series being the most affected; against the *A. fluviatilis* group, the 6 days-a-week spraying is shown to be the most effective, where economically feasible. It was found that in *A. fluviatilis* and *A. varuna* there are definite biological differences between house and outside populations, both in respect to their infection rates and their anthropophilic indexes; *A. varuna* exhibited such extreme differences as to furnish evidence contributory to the previously enunciated hypothesis that this name covers more than one species or biological race.

**On the bionomics of *Anopheles culicifacies* Giles, III, IV, R. PAL** (*Jour. Malaria Inst. India*, 6 (1945), No. 2, pp. 217–241, illus. 10).—The following parts are included (E. S. R., 91, p. 58):

III. *The behaviour of adults* (pp. 217–238).—The density of this species of mosquito—prevalent in Delhi throughout the year—was found highest during spring and the hot humid July–September period. The correlation between seasonal prevalence and meteorological and breeding conditions is discussed. The density per man-hour was 3.4 during normal years and 25 during a regional epidemic; a density of about 5.4 per man-hour appeared to be the limit below which transmission of malaria by this species does not occur. Temperatures of 25° to 30° C. combined with relative humidities of 60 to 80 percent seemed to be the most favorable climatic conditions for longevity and activity of the species. There was no evidence of true hibernation of the adult, but in those regions of India where the winter is comparatively mild it has been found to hibernate as fourth stage larvae; the species apparently has no summer period of aestivation. The most favored daytime resting

places were inside dark houses and cattle sheds. *A. culicifacies* is not a habitual feeder on man, attacking indifferently man and cattle, depending on a number of factors. Precipitin tests during an epidemic showed a higher percentage of human-fed specimens; the maxillary index proved to be the same in both epidemic and nonepidemic years. Biting activity gradually decreased after midnight. After oviposition in summer the ♀ was observed to return for a second blood feeding the same night. Night collections and marking tests indicated a considerable daily turn-over of the population in houses. At dusk there appeared to be a strong attraction toward light, and most of the individuals left the houses at this time; they failed to return to the same resting place for a blood feeding after oviposition. *A. culicifacies* does not ordinarily fly more than 0.5 mile from its breeding place; it may, however, travel long distances, especially where there is no barrier on its path.

IV. *Hypothesis of the races of A. culicifacies* (pp. 239-241).—Intensive morphological studies on eggs, larval chaetotaxy, adult polytaxy, wing measurements, and ♂ genitalia of this mosquito from various parts of India revealed no difference indicative of the existence of separate races.

The behaviour of *Anopheles fluviatilis*.—IV, Experiments on the behaviour of gravid females, D. K. VISWANATHAN, T. R. RAO, and T. S. RAMA RAO (*Jour. Malaria Inst. India*, 6 (1945), No. 2, pp. 243-245).—Of 285 fully dusted gravid ♀♀ released in a hut or tent on four occasions, 15 were found to return for blood after oviposition within a few hours following release and 2 the next night. The effect of this behavior on a rational spacing of spray-killing is discussed. This must be designed to destroy broods of 48-hr. and 72-hr. feeding cycles conjointly to insure satisfactory results, irrespective of the season of year. Spraying for 2 consecutive days separated by 1 and 2 free days alternately is recommended where impossible to combine antiadult with antilarval measures.

Estudo sobre *Flebotomus* no Vale Amazonico.—Parte III, Descrição de *F. servulolimai* e *F. wilsoni* (Diptera: Psychodidae). Parte IV, Descrição de *F. cerqueirai*, *F. dreisbachi*, *F. meirai*, e *F. ferreirai* (Diptera: Psychodidae), O. R. CAUSEY and R. G. DAMASCENO (*Mem. Inst. Oswaldo Cruz*, 42 (1945), No. 3, pp. 635-660, illus. 34).—In these two installments (E. S. R., 93, p. 739) six new species of blood-sucking flies of the genus *Phlebotomus* are described.

Les glossines de l'Afrique Occidentale Française [The Glossinas of French East Africa], H. GASCHEN (*Basel, Switz.: Verlay für Recht und Gesell.*, 1945, pp. 131+, illus. 115).—A monograph on the species of *Glossina*—the tsetse fly group, so important as vectors of pathogenic organisms to man and animals—in this African region.

A new genus and species of chigger, *Chatia setosa* (Trombiculidae: Acarina) from northwestern United States, J. M. BRENNAN (*Jour. Parasitol.*, 32 (1946), No. 2, pp. 132-135, illus. 7).—*C. setosa* n. gen. and sp. is described and illustrated.

Tick collections at Army installations in the Fourth Service Command, S. J. CARPENTER, R. W. CHAMBERLAIN, and L. PEEPLES (*Ent. News*, 57 (1946), No. 3, pp. 71-76).—Collections of ticks in this seven-State area (Ala., Fla., Ga., Miss., Tenn., and N. and S. Car.) are summarized in an annotated list of species of *Amblyomma*, *Dermacentor*, *Haemaphysalis*, *Ixodes*, *Rhipicephalus*, and *Ornithodoros*; 3,227 specimens representing 47 localities are included.

Control of *Boophilus australis* in the Argentine by the gamma isomer of hexachlorocyclohexane ("Gammexane"), C. N. AULT (*Nature [London]*, 157

(1946), No. 3995, pp. 699-700).—Recent trials are said to indicate that this cattle tick can be controlled by dips containing Gammexane; no adverse effects on the test animals were observed.

**Control of the American dog tick, a vector of Rocky Mountain spotted fever—preliminary tests.** R. D. GLASGOW and D. L. COLLINS (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 235-240, illus. 2).—In this emergency work (1945) in a Long Island, N. Y., locality where spotted fever had been dangerously prevalent, screening tests were first made to find the acaricides which had most promise for early large-scale experimental use in the field; this narrowed down the list of most promising materials to DDT alone, Gammexane alone, pyrethrins alone, DDT plus pyrethrins, Gammexane plus pyrethrins, DDT plus nicotine, and Gammexane plus nicotine, each of which have now been given preliminary testing under field conditions. A No. 2 fuel oil solution containing as little as 0.250 percent DDT plus 0.0625 percent pyrethrins, used at a rate equivalent to 2 qt. per acre (but diluted with additional fuel oil to become equivalent to 8 qt. per acre of 0.0625 percent DDT plus 0.0156 percent pyrethrins), appeared under the experimental conditions to be enough to assure practical control; even half of these percentages used at the same rate per acre gave a surprisingly complete kill. In this preliminary work, a general orientation of the problem has been made—apparently sufficient to justify tentative plans for rather large-scale control experiments using DDT alone and in combination with pyrethrins, and possibly also with nicotine and with rotenone; if Gammexane should become available for large-scale tests, it also should be included. In the case of spotted fever, the persistence of the causal agent through the egg stage of the tick vector appears to render long continued use of even the most effective tick control measures necessary if the disease is to be thoroughly rooted out.

**Use of D. D. T. against sheep ticks, *Ixodes ricinus* L.,** G. B. S. HEATH, J. G. MITCHELL, and K. L. BLAXTER (*Vet. Jour.*, 102 (1946), No. 5, pp. 130-140, illus. 2).—Of 27 trials of 12 emulsions containing DDT as antitick sheep dips at 0.1 and 2 percent, 15 were classed as excellent or good as compared with a commercial dip; the remaining 12 were classed as fair, poor, or nil in protection. Though DDT may prove a valuable aid in tick control, the results were too variable to allow specific recommendations based on the findings. Physical and chemical data gave no clear indication as to the cause of the irregular results, but a high deposition of DDT in the fleece appears to be associated with good protection. Day-to-day observations of individual ticks on DDT-dipped sheep showed that the majority were unable to engorge; this may account for some of the apparent discrepancies in results. An appendix, presenting a Statistical Note on Tick Control Experiments, by K. L. Blaxter (pp. 137-140), is included.

***Atricholaelaps sigmodoni*, a new species of mite parasitic on the cotton rat, and notes on the genera *Atricholaelaps* and *Ischnolaelaps* (Acarina: Laelap-tidae),** R. W. STRANDTMANN (*Jour. Parasitol.*, 32 (1946), No. 2, pp. 164-169, illus. 7).

**The performance of the queen bee,** W. C. ROBERTS. (Univ. Wis. coop. U. S. D. A.). (*Amer. Bee Jour.*, [86] (1946), [No. 5], pp. 185-186, 211, illus. 1).—The performance of queen bees can be improved by genetic and enviroanal means. Improper rearing produces inferior queens. Experiments with 63 artificially inseminated sister queens in 5 different groups indicated their performance to be equal to that of their naturally mated sisters. There was some variability within groups, but striking differences between groups were observed. Artificial insemination and improved queen-rearing methods are points to be stressed in the development of superior strains of bees.

**Save those bees**, G. M. LIST (*Colo. Farm Bul. [Colorado Sta.]*, 8 (1946), No. 3, p. 3).—A practical account.

**DDT as a threat to bees**, T. B. MITCHELL (*Res. and Farming [North Carolina Sta.]*, 4 (1946), *Prog. Rpt. 3*, pp. 1, 2, 11).—DDT is discussed from the viewpoint of its influence on beneficial insects, including parasites, predators, scavengers, wild bees, and the honeybees. The author points out that there are several unknowns relating to this entire question and that growing crops must be protected, but that these other factors must be considered in due time.

**The mode of toxic action of dinitro compounds on the honeybee**, G. J. GOBLE and R. L. PATTON. (Cornell Univ.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 177–180, *illus. 4*).—The facts brought to light by these studies are summarized as follows: Dinitro salts (sodium salt of 3,5-dinitro-*o*-cresol and sodium salt of 2,4-dinitro-*o*-cyclohexylphenol) are very highly toxic to honeybees; the dinitro compounds do not decompose but remain potentially toxic for some time after application; there is a varietal difference in the attractiveness of sprayed blossoms to bees; the median lethal dose for the sodium salt of 3,5-dinitro-*o*-cresol is 0.0021 mg. per bee; doses as small as 0.00004 mg. of the sodium salt of 3,5-dinitro-*o*-cresol have a measurable effect on the adult bee; and the toxic effect of these compounds is faster at lower temperatures.

**Sulfathiazole as a medication for American foul brood disease of honeybees**, J. P. JOHNSON and R. STADEL. (Conn. [New Haven] Expt. Sta.). (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 141–144).—All colonies treated at the rate of 0.5 gm. to 1 gal. of mixture—regardless of the method used—reacted to some degree favorably, although the chemical in water was not consumed in amounts sufficient to eliminate the disease entirely in one season. When the same proportion was added to equal parts of sugar and water, the mixture proved more attractive to the bees, resulting in a higher consumption and elimination of the disease in less than one season. When used as a medication, sulfathiazole was deposited in the honey and the amount so deposited increased with the amount of the mixtures consumed; since the quantity found in the few samples analyzed amounted to only 20 p. p. m. (9.07 mg. to 1 lb. of honey), and since the treatment in man is in grams per day, a large factor of safety exists. Fall treatments after the surplus honey is removed and spring treatments before surplus honey is being made are considered desirable, especially if the disease can thus be eliminated. Since the paper reports only a single season's work, however, beekeepers should confine their efforts at present strictly to an experimental basis until definite recommendations are made to them by State or Federal authorities, and all honey produced by treated colonies should be kept out of commercial channels until tolerances are established.

**An experimental report on the treatment of American foulbrood with sulfa**, G. H. CALE and E. KIRLIN (*Amer. Bee Jour.*, [86] (1946), [No. 5], pp. 195–196).—Promising results are reported.

**Bakelite varnish for extracting equipment**, W. R. ROBBINS. (N. J. Expt. Stas.). (*Amer. Bee Jour.*, 86 (1946), No. 6, p. 236).—The successful experience of the author with this material and the lack of any apparent disadvantages to date lead him to consider it worthy of trial by those wishing to protect their honey against metallic corrosion. It has proved satisfactory in protecting metal surfaces from distilled water for storage tanks where only a fraction of 1 p. p. m. would be objectionable.

## ANIMAL PRODUCTION

**Estimation of apparent digestibility coefficients by means of an inert "reference-substance,"** C. R. BARNICOAT (*New Zeal. Jour. Sci. and Technol.*, 27 (1945), No. 2, Sect. A, pp. 202-212, illus. 3).—A method is described for estimating the digestibility of feeding stuffs by feeding with the ration a known proportion of an insoluble and unabsorbable substance, (chromic acid) and estimating the ratio of nutrients to Cr<sub>2</sub>O<sub>3</sub> excreted, thereby avoiding the quantitative collection of excreta. The digestibility percentages found were uniformly low due to incomplete elimination of Cr<sub>2</sub>O<sub>3</sub> during the collection period. By applying an empirical correction to the calculation, however, results close to the standard method were obtained, particularly with fixed diets.

**A new instrument for measuring animals: Standardization of measurements of cattle,** T. M. OLBRYCHT (*Empire Jour. Expt. Agr.*, 13 (1945), No. 52, pp. 199-202, illus. 5).—A metal zoometrical rule designed by the author to measure both large and small animals is described, and an attempt at standardization of measurements is made by listing those for cattle "in the order which is most convenient, speedy, and least disturbing to the animal."

**Adaptability of cattle to tropical and subtropical climates,** R. W. PHILLIPS. (U. S. D. A.). (*Cattleman*, 33 (1946), No. 1, pp. 16-17, 29, 32, 36-37, illus. 6).—The facts summarized "indicate that cattle of different types react differently to the hot environments of tropical and subtropical areas. These differences may be seen in the immediate response of animals to high temperatures as indicated by increased respiration rates, higher body temperatures, and their grazing habits, and by long-term responses which may be measured in terms of economically important characters such as level of milk production in dairy animals and rate of growth in beef animals. The available data indicate that zebu cattle are better able to maintain a normal body temperature than European cattle when atmospheric temperatures are high, and that some zebu blood is desirable in the subtropical region adjacent to the Gulf of Mexico.

"Careful review of the available data reveals that we do not yet have enough experimental evidence to determine the amount of zebu blood that will be most desirable in the Gulf coast area. It may vary in different portions of the area, depending upon the type of forage available, whether or not calves are sold from the cows for slaughter or for use as feeders, and perhaps other factors. There is also a paucity of clear experimental information on how best to use hybrid animals in further breeding operations. Should new types be established, and if so, at what level of zebu blood? Or should a continuous system of crisscrossing be used, in which generations of females are mated alternately to zebu and Hereford (or Shorthorn or Angus or some other breed) bulls? These are questions that need careful attention by cattle breeders and experiment stations if the utilization of stock having zebu blood is to be carried out most effectively."

**The beef cattle industry in the Gulf Coast States,** L. G. SMITH (*Cattleman*, 33 (1946), No. 1, pp. 18-28, illus. 3).—The history of the industry in this region is briefly depicted.

**Maximum utilization of roughage and pasture by steers,** G. A. BRANAMAN and C. M. HARRISON (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 344-353, illus. 2).—Continuing an earlier study of the wintering phase (E. S. R. 94, p. 511), the animals there fed were used in a study of pasture management and fattening rations. The calves gaining about 1.6 lb. daily during

the winter made cheaper gains than calves fed similar feeds in amounts to produce 0.9 lb. daily. There was a difference in weight of approximately 100 lb. in May. Calves fed liberally on corn silage produced cheaper gains than those fed hay and corn to make similar gain. The calves gaining faster during the winter were ready for market sooner than the lighter and thinner calves, and they tended to make more total gain for the corn eaten. They showed a greater money return above cost of calf and feed than the corresponding lots of lighter calves. Grazing without grain cut the costs considerably for cattle of both weights. The lighter and thinner calves made considerably faster gains on pasture alone than did those wintered on better rations. Faster gains on pasture alone were made the first 60 days, or during June and July, than during the next 48 days. The lighter calves did not overtake the heavier calves in either weight or finish in 108 days of pasturing.

Feed cost for gains during fattening varied from \$12.59 to \$16.74. The calves grazed 108 days without grain, and those in the well-wintered lot especially, were highest in costs. Lowest cost was for the well-wintered calves grazed 60 days before grain feeding. The most profitable group of calves were well-wintered, grazed 60 days, and fed corn and soybean meal 94 days. They dressed 59 percent and showed a return of \$26.70 above cost of feeder calf and feed. Other lots ranked as follows: Well-wintered and grazed 108 days, \$22.67; lightly wintered and grazed 108 days, \$19.60; lightly wintered and grazed 60 days, \$18.62; well-wintered and grain-fed with pasture, \$16.46; light-wintered and grain-fed with pasture, \$11.87.

**Dehydrated potatoes and alfalfa silage for fattening steers,** W. E. CONNELL, L. E. WASHBURN, and S. S. WHEELER (*Colo. Farm Bul. [Colorado Sta.]*, 3 (1946), No. 3, pp. 6-8).—Lots of 10 or 11 steers fed for 146 days made average daily gains per head of 2.67 lb. on a mixed ration containing 7.22 lb. of alfalfa hay and no silage; 2.57 lb. on a corresponding ration with 4.59 lb. alfalfa hay and 6.04 lb. of alfalfa silage; 2.47 lb. with 4.39 lb. alfalfa hay and 6.13 lb. alfalfa-corn silage; 2.63 lb. with 5.37 lb. alfalfa hay and 6.04 lb. alfalfa silage preserved with phosphoric acid; and 2.57 lb. with 4.85 lb. alfalfa hay and 6.01 lb. corn silage. On terms of feed replacement value, the silages fed averaged about one-fifth the value, pound for pound, of alfalfa hay. Slaughter data revealed that the steers receiving alfalfa-acid silage produced the highest ranking carcasses, yielding 63.1 percent, compared with 62.5 percent for the other two alfalfa silages and 62.2 percent for corn silage. A similar lot of 10 steers fed the same mixed ration as above but with 7.77 lb. of dehydrated potato cubes and no alfalfa hay made an average daily gain of 2.54 lb. per head. These cubes were deemed "equal to ground corn in feeding value when fed with dried beet pulp to fattening steers."

**Rations for fattening cattle in Arizona,** E. B. STANLEY (*Arizona Sta. Bul.* 198 (1945), pp. 16).—In the abstract of this publication previously printed (*E. S. R.*, 95, pp. 90-91), the words "with wheat" in the first line on page 91 should be omitted.

**Cobalt as a preventive of "pining" in Cornwall and Devon,** J. B. E. PATTERSON (*Nature [London]*, 157 (1946), No. 3991, p. 555).—Experiments in these areas are noted in which significant gains in sheep followed the feeding of cobalt.

**Swine pastures save feed and increase profit,** W. N. McMILLEN (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 333-337, illus. 2).—In a comparison of limited feeding on pasture and feeding on a concrete floor, the average daily gains per head for 4 lots of 12 pigs each for feeding periods of 92 to 107 days were 1.49 lb. when fed ground corn supplemented with meat scrap and soy-

bean oil meal 1 : 1 and minerals on rape pasture; 1.35 and 1.4 lb. on rape pasture when the corn was limited to 80 and 60 percent of that in lot 1 for several weeks; and 1.33 lb. with the same ration as lot 1 plus 5 percent of alfalfa meal and fed on a concrete floor. The respective amounts of feed per 100 lb. gain were 391, 421, 389, and 460 lb. Results with brood sows and fall pigs on rye pasture are also briefly noted.

**Cull peas for fattening hogs in dry lot,** W. P. LEHRER, JR., and C. W. HODGSON (*Idaho Sta. Cir. 107 (1946), pp. [4]*).—In an 84-day test with four lots of purebred Duroc and Poland China feeder pigs, using a basal grain mixture of rolled wheat, ground cull peas, and ground alfalfa either 75 : 20 : 5 or 60 : 35 : 5 and a mineral mixture of oystershell, steamed bone meal, and salt 40 : 40 : 20, the lot consuming 7.14 percent of meat meal as a protein supplement made an average daily gain of 1.60 lb. per head at a net return per head of \$3.85. Lots receiving 6.56 percent of ground cull peas, 7.49 percent of meat meal, and 6 percent of ground peas made corresponding daily gains of 1.35, 1.68, and 1.54 lb., respectively, with net returns of \$2.44, \$4.85, and \$4.70. The hogs on the ration containing 35 percent peas made faster gains and required less feed per 100 lb. of gain than similar hogs on the ration containing only 20 percent peas. Meat meal was considerably more efficient than ground peas as a protein supplement for the grain ration containing only 20 percent of peas, but only slightly more efficient in supplementing the grain ration containing 35 percent peas.

"Cull peas may be used to advantage in replacing part of the grain ration, thus making larger quantities of wheat available for human consumption. They may also be used to stretch our protein supplements during the present shortage of animal proteins."

**The story of Durocs, the truly American breed of swine,** B. R. and G. G. EVANS (*Peoria, Ill.: United Duroc Rec. Assoc., 1946, pp. 553+, about 270 illus.*).

**Poultry lighting for egg production,** J. B. DOBIE, J. S. CARVER, and J. ROBERTS (*Washington Sta. Bul. 471 (1946), pp. 27, illus. (15)*).—This experiment was designed to determine the effect of artificial lights on poultry egg production. Studies included tests of the optimum amount of light to be provided, both as to intensity and length of day; the proper time of day at which the light should be supplied; the best kind of light; and combinations of these various problems. The birds used were carefully selected White Wyandotte pullets that had begun to lay, 20 birds being placed in each battery-type pen in individual cages. There was also a test on a commercial basis, using 288 New Hampshire pullets housed in a commercial laying house.

The results as a whole indicated that the time at which artificial light is given is not important provided a total of 13 hr. of Mazda incandescent light per day is supplied. Any decrease from 13 hr. resulted in decreased egg production, and any increase above 13 hr. did not result in enough increase in egg production to warrant recommendation.

Provided the 13 hr. was received, there was no significant difference on egg production in the effect of intensities of Mazda incandescent light varying from 1 to 31.3 foot-candles, or in the effect of Mazda, Mazda plus CX ultra-violet, ruby red, and red fluorescent light on egg production. Eight hr. of ruby red or red fluorescent light was insufficient to maintain high production.

**Keeping the laying house full,** J. A. DAVIDSON, C. M. McCRARY, and C. G. CARD (*Michigan Sta. Quart. Bul., 28 (1946), No. 4, pp. 281-286*).—Continuing work previously noted (*E. S. R., 91, p. 327*), 252 October-hatched White Leghorn pullets averaged at 14 weeks of age 2.36 lb. in weight and a total

feed consumption of 16.5 lb. per bird. From March 1 to September 30 their average egg production was 101.7, which is deemed reasonably satisfactory, although somewhat lower for the same period when compared with birds hatched during the spring months. "It is evident that 'off-season' pullets can be successfully reared and will produce reasonably well. This makes possible more efficient utilization of labor, equipment, and the laying house. The problem of intestinal parasites is less, and the problem of respiratory diseases was not encountered. . . . More work should be done on the best schedule and feeding practice."

**Feeding and management of birds in laying cages.** L. N. DELRY (*New Mexico Sta. Bul. 328 (1946)*, pp. 11, *illus.* 5).—In an extension of the study previously noted (E. S. R., 85, p. 390), a feeding test was made with 2 cages of 96 hens each to ascertain the value of dried buttermilk v. soybean oil meal in the ration. In each of the 3 yr. the cage receiving 4 percent of dried buttermilk had a higher average egg production per bird, but the average income per bird per year was only 9 ct., a difference of only 2 percent.

Single-Comb White Leghorns, Rhode Island Reds, and a cross between these two breeds were used in the cages. The crossbred birds gave the highest egg production, averaging 26.8 eggs per bird per year more than the purebred White Leghorns. The crossbred birds were well adapted to the cage system of management, giving decidedly better results in cages than in floor pens under average conditions of care and management, largely because the cages practically eliminated broodiness.

During the 10 yr. that White Leghorns have been kept in cages, they laid more eggs each year than the birds in floor pens. However, the data indicate that this difference in production resulted largely from the fact that the environment of the caged birds was the more favorable.

Laying cages helped to prevent molt in early hatched birds. In these tests pullets which began laying about the middle of July were carried through a 12-mo. laying period with almost no molt.

More cracked eggs were produced in laying cages than in floor pens, but "this problem can be solved by providing adequate rations and by avoiding strains of birds which have any inherent weakness of shell texture."

The interior quality of eggs produced by caged birds was high. The yolk was very uniform in color and the flavor excellent.

**Practical guide to battery egg production.** L. ROBINSON (*Woking, Surrey, [Eng.]: John R. Harvey, S. P. E. A. Supplies, [1946]*, pp. 97 +, *illus.* 34).

**Composition and productive energy of poultry feeds and rations.** G. S. FRAPS (*Texas Sta. Bul. 678 (1946)*, pp. 37).—Based on an extensive series of investigations (E. S. R., 58, p. 868; 81, p. 408; 90, pp. 89, 518; 93, pp. 184, 334), methods are presented for calculating the productive energy and digestible protein of feeds for chickens from the chemical analysis by the use of production coefficients. Extensive tables present digestion coefficients, energy-production coefficients, average composition, minimum guarantee, productive energy, and digestible protein of many feeds used in poultry rations. Calculation of the productive energy in a number of mixed rations recommended by various experts gave average values in therms per 100 lb. as follows: All-mash chicken starter, 81.6; all-mash growing diet 87.9, and with grain, 91.7; all-mash laying diet 83.1, and with grain, 89.5; and all-mash breeding diet 81.4, and with grain, 86.5. The influence of composition of the ration on composition of the fowl is discussed with emphasis on the fact that fowls making the same gains in weight are not necessarily of the same degree of fatness. It is suggested that feeding experiments with growing fowls should

include data on the quality of the fowl, particularly fat content, since higher gain in weight per unit of feed may result in a fowl containing less fat and of poorer quality than fowls making lower gains in weight.

**Photolysis of riboflavin in poultry feeds**, O. E. STAMBERG and C. F. PETERSEN. (Idaho Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 394-395).—When exposed to direct sunlight, with several stirrings, a laying mash lost in 9 days 10.60 percent of its riboflavin and a breeder mash 13.52 percent. Another poultry feed lost only about 15 percent in a 2-week period. It is indicated that in feeds the loss is less rapid than in milk (E. S. R., 93, p. 518) or other solutions.

**Shark meal as a protein supplement in chick rations**, S. P. MARSHALL and G. K. DAVIS (*Poultry Sci.*, 25 (1946), No. 4, pp. 381-386, illus. 1).—Shark meal prepared by a wet process method was compared with roller process powdered skim milk as a protein supplement in chick rations containing 15.5 percent of total crude protein. Four pairs of lots containing 25 chicks per lot were fed through 12 weeks of age, using an equalized feeding method. Seventy-seven birds that finished the experiment on the shark meal rations gained an average of 776.4 gm., and 83 that finished on the powdered skim milk rations made an average gain of 746.3 gm. The difference in average gains was not significant at the 5-percent level. Nitrogen present in urea and in nonprotein nitrogen other than urea in amounts equivalent to 8.19 percent of crude protein ( $N \times 6.25$ ) contributed by shark meal to one ration apparently did not interfere with the efficiency of the utilization of these rations. Feather picking and cannibalism were common among the birds fed each of the rations. Control measures lessened but failed to eliminate these vices. No fishy or other off-flavor was observed in the broiled meat of chicks fed through 12 weeks of age on rations containing from 9.0 to 13.58 percent of shark meal.

**Feed utilization in growing chickens in relation to shank length**, E. W. GLAZENER and M. A. JULL. (Md. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 355-364, illus. 4).—Data were collected on 222 short-shanked and 138 long-shanked New Hampshires, and 196 short-shanked and 86 long-shanked Plymouth Rocks. The progeny from the long-shanked strains in both the New Hampshires and Barred Plymouth Rocks tended to grow faster and utilize feed better than the progeny from the short-shanked strains, although the early growth and efficiency were better in the short-shanked than in the long-shanked Barred Plymouth Rocks, probably as the result of heterosis.

The degree of variation was greater in body weight than in shank length, and the birds with the longer shank tended to be heavier at 10 weeks of age.

**Observations on the choline requirements of hens**, H. L. LUCAS, L. C. NORRIS, and G. F. HEUSER. (Cornell Univ.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 373-375).—The present study was a preliminary one designed to test whether a diet known to be low in choline was complete with respect to other nutrients required for egg production and hatchability. Single-Comb White Leghorn hens in good production were used, with eight hens on each of the experimental diets. On a diet composed principally of purified and alcohol-extracted ingredients, and which contained 0.03 percent of choline, egg production and hatchability were only slightly lower than on the same diet supplemented with choline so that the total content was 0.21 percent. It appeared that, under these conditions, the hens synthesized substantial amounts of choline. These observations were supported by certain calculations which indicated that hens, especially high producers, may synthesize significant amounts of choline under practical conditions.

**Riboflavin and manganese supplements for high wheat poultry rations, G. L. McClymont and L. Hart** (*Agr. Gaz. N. S. Wales*, 57 (1946), No. 4, pp. 219-222).—Experiments are reported in which the hatching percentages were determined with rations containing various wheat products and supplemented or unsupplemented with riboflavin and manganese salts. The authors conclude that "rations with a high proportion of wheat and/or wheat meal, with large or small amounts of meat meal and with or without green feed, need supplementing with riboflavin-rich feeds and manganese to obtain good hatchability. Rations with a high proportion of bran and pollard do not appear to need such supplements."

**Effect of riboflavin intake on the content of egg whites and yolks from individual hens, O. E. Stamberg, C. F. Petersen, and C. E. Lampman.** (Idaho Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 320-326, illus. 2).—In this study the eggs laid by individual hens were analyzed for riboflavin during a period of several months at various levels of riboflavin intake. White and yolks were also analyzed separately. The riboflavin analyses were made by the method of Peterson, Dearstyne, Comstock, and Weldon (*E. S. R.*, 95, p. 160). Four Single-Comb White Leghorns pullets were used in the experiments, housed in individual laying cages without access to droppings.

The pullets produced eggs of low riboflavin content when fed a mash containing 2.2  $\mu\text{g./gm.}$  All of the four responded to a mash containing 7.5  $\mu\text{g./gm.}$  of riboflavin, producing eggs of higher riboflavin content, but each responded to a different degree. Increasing the riboflavin content of the mash to 15.7 and later to 26.7  $\mu\text{g./gm.}$  produced practically no further increase. At each level of riboflavin intake the concentration of riboflavin of the eggs produced by an individual pullet varied somewhat from day to day, but it was within a certain level depending on the intake. The first egg of a clutch was generally lower in riboflavin than other eggs.

In the case of two pullets the whites and yolks were analyzed separately during the experimental period of about 5 mo. One hen produced eggs consistently higher in riboflavin concentration in the white and one hen consistently higher in the yolk. Of the four hens studied, three had a higher concentration of the vitamin in yolks. Results on internal yolks from hens which were sacrificed confirmed previous observations that about 8 days were required for the hens to produce eggs at a higher or lower riboflavin level when feeds were shifted. All of the internal yolks of a hen changed at about an equal rate. It is concluded that "all hens respond to an increase in riboflavin intake up to a certain level and produce eggs of a higher riboflavin content. This is important in relation to egg quality as a food."

**The influence of different levels of dietary calcium upon egg-shell thickness, with a study of the relationship between egg-shell thickness and porosity, C. Tyler** (*Jour. Agr. Sci. [England]*, 36 (1946), No. 2, pp. 111-116, illus. 2).—Thickness measurements made on eggshells from hens fed high-, normal-, and low-calcium diets are reported. The low-calcium diet caused a gradual thinning of the shell, but no soft-shelled eggs. The high-calcium diet did not lead to a general increase in shell thickness, and a number of soft-shelled eggs were found. The position of the egg in a clutch appeared to have no influence on shell thickness or uniformity of shell thickness. No relationship was noted between shell thickness and porosity for eggs produced on normal-calcium diets, but high- or low-calcium diets resulted in the production of shells in which thickness and porosity were significantly and negatively correlated.

**The effect of estrogens upon the meat quality of old cocks and hens, P. D. STURKIE.** (N. J. Expt. Stas.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 365-368).—Thirty males 18 to 20 mo. of age were successfully treated with diethylstilbestrol and dienestrol. The diethylstilbestrol, in the form of pellets (20 to 25 mg.), was implanted into the shanks or necks of the birds, and it also was injected into shanks and necks. Dienestrol was injected into these sites. Most of the birds received only one implantation or injection. All males were killed on the twenty-ninth day and graded, and later were cooked and scored as to eating quality.

The treatments were effective in improving the grade of the carcass, but they did not increase the gains in weight significantly nor improve the eating qualities of the meat appreciably. Old hens, 2½ yr. of age, were hormonized for a 26-day period, 50 being fed dianisylhexene in the feed at the rates of 0.01 and 0.005 percent; 16 dienestrol in the feed (0.01 percent); and 20 had pellets of diethylstilbestrol implanted into the necks and shanks. The treatments did not influence the feed consumption, egg production, gain in body weight, or market quality of the carcasses.

**Amount of breast meat and live and dressed grades in relation to body measurements in 12-week-old purebred and crossbred chickens, C. O. FRISCHKNECHT and M. A. JULL.** (Md. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 330-345, illus. 2).—The mean values are reported of live body weight, amount of breast meat, and other measurements related to body conformation and market condition for the 256 12-week-old purebred and crossbred progeny of Cornish, New Hampshires, Barred Plymouth Rocks, and their crosses. The degree of variability in these values was greatest for the live body weight and smallest for the shank and keel lengths. The difference in the mean live body weight between the males and females was significant. The mean values of breast depth, body depth, keel length, shank length, observed cross-section breast area, and the ratio of shank length to cube root of body weight tended to be greater in the males than in the females. The mean values of the amount of breast meat, breast width, and breast index were slightly larger in the females than in the males. The mean value of the shank length was only slightly larger than the mean keel length in these progeny.

Live body weight was the best criterion of the quantity of breast meat on chickens at 12 weeks of age, both purebred and crossbred. Breast index did not prove to be a good measure of breast meat. The mean live body weight was significantly larger in the progeny of the Cornish × New Hampshire mating than in the progeny of each of the following matings: Cornish × Barred Plymouth Rock, Barred Plymouth Rock × New Hampshire, purebred Cornish, purebred Barred Plymouth Rock, and purebred New Hampshire. The amount of breast meat in this cross was significantly greater than for any other crossbred or purebred progeny.

Live and dressed grade observations indicated that breast index, as defined in this study, was not a good index of market grade, and observed cross-section breast area proved to be the best criterion. The correlation ratios between flesh measurements and grade were higher than the correlation ratios between shank length and grade. The fastest growing chickens tended to grade the highest. Females tended to grade higher than males, but in the AA grade birds breast meat as a percentage of live weight was higher in males than in females. The strain of New Hampshires was superior to the strain of Barred Plymouth Rocks used in this study with respect to ability to transmit roundness of breast and superior grade of bird in the

progeny. Crossbreeding, involving the use of a Cornish male with New Hampshire and Barred Plymouth Rock females, produced a higher percentage of grade AA and grade A birds than purebred New Hampshire and Barred Plymouth Rock matings.

**Breeding Leghorn chickens to increase the life span.** R. L. BRYANT (*Virginia Sta. Tech. Bul.* 99 (1946), pp. 8, illus. 1).—An experiment was conducted to determine the feasibility of selective breeding to increase the length of life of Single-Comb White Leghorn chickens. From the original stock of 105 females, two strains were established, one bred for a low percentage of deaths and the other bred for a high percentage of deaths.

Eliminating birds which died from accidents, the deaths during the starting period, 1 day to 8 weeks of age, amounted to 8.05 percent for the short-life strain and 3.39 percent for the long-life strain. During the growing period, 8 to 20 weeks of age, the nonaccidental deaths were 3.99 and 2.50 percent, respectively, and during the laying period, 140 to 525 days of age, they were 29.66 and 17.07 percent, respectively. By the end of the 5-yr. breeding period the average length of life, based on a maximum length of life of 525 days, was 43.9 days greater for the birds in the long-life strain than for those in the short-life strain.

The experiment is deemed to show that resistance to disease and length of life of the domestic fowl can be influenced by selective breeding and progeny testing.

**A study of oxygen transport in the blood of young and adult domestic ducks.** H. H. ROSTORFER and R. H. RIGDON. (Univ. Ark.). (*Amer. Jour. Physiol.*, 146 (1946), No. 2, pp. 222-228, illus. 5).—The oxygen capacity, hemoglobin content, color index, and dissociation curve for blood are compared for young and adult domestic ducks.

**Undersökningar över gasungarnas behov av D-vitamin samt utprovning av en praktisk metod för uppfödning av gäss** (The vitamin D requirements of goslings), N. OLSSON (*Lantbr. Högsk. Husdjursforsöksanst. Meddel. No. 21* (1946), pp. 33, illus. 11; *Eng. abs.*, pp. 32-33).—The vitamin D requirements of Roman, Toulouse, and crossbred goslings during the first weeks after hatching were investigated. Batteries were used to prevent ultraviolet radiation, and vitamin D was supplied to an all-mash ration in the form of cod-liver oil. The method of battery feeding is described. Goslings of Roman geese required for satisfactory growth and normal bone calcification about 30 chick units of D-vitamin (equivalent to the antirachitic effect of 0.3γ vitamin D<sub>2</sub> on chicks) per 100 gm. of fodder, containing 2.02 percent of calcium and 1.01 percent of phosphorus in the dry matter of the ration. Under the same conditions goslings of Toulouse and other breeds of rapid growth required at least 35 chick units of D-vitamin per 100 gm. of fodder. However, great individual differences in vitamin D requirements were noted, depending on varying external conditions and probably on genetic factors.

**Influence of light intensity on ovulation in turkeys.** V. S. ASMUNDSON, F. W. LORENZ, and B. D. MOSES. (Univ. Calif.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 346-354, illus. 4).—Bronze hens from three strains and from various combinations of those strains were divided into groups of 10 on the basis of ancestry, date of hatch, and body weight. The groups were placed in separate pens and, except for the unlighted control group, were subjected to different light intensities. Electric lights were turned on in the morning to furnish a 13-hr. day of artificial plus natural light. A minimum light intensity of about 2 footcandles produced maximum response (or nearly so) as measured by the average number of lighted days before the vagina was

perforated and egg production began. Light intensities of 0.3 to 1.0 foot-candle produced a slower response; and dim lights (less than 0.1 foot-candle) had no effect (according to a comparison with unhoused, unlighted birds). Housing without lights retarded egg production.

The total average number of eggs laid to the end of May was about in proportion to the time when the birds started to lay. The starting date of laying and the number of eggs laid before March 1 had no apparent effect on the number produced in April and May. The earlier eggs in the brightly lighted pens were relatively small; those laid in March were slightly smaller than those laid by hens of similar ancestry in the dimly lighted or unlighted pens. The maximum weight attained by birds brightly lighted was less than that attained by those dimly lighted or not lighted at all. It was apparently governed by the age of the hens when they started to lay and by the weight attained at that age.

The pigeon, W. M. LEVI (*Columbia, S. C.: R. L. Bryan Co., 1945, 2 ed., pp. 512+*, *illus. 785*).—This comprehensive and copiously illustrated treatise (*E. S. R., 87, p. 562*) again deals with such phases as the relationship of pigeon and man (pp. 1-15), breeds and varieties (pp. 16-153), anatomy and physiology (pp. 154-207), genetics (pp. 208-249), diseases, parasites, and pests (pp. 279-333), feeds and feeding (pp. 334-384), housing (pp. 385-415), commercial squab production (pp. 416-440), exhibition, training, etc. (pp. 441-473), and bibliography (pp. 476-489).

## DAIRY FARMING—DAIRYING

Live weight versus metabolic body size in dairy cows and goats, W. L. GAINES. (*Ill. Expt. Sta.*). (*Jour. Dairy Sci., 29 (1946), No. 5, pp. 259-272, illus. 1*).—The author discusses the two philosophies with special reference to lactating maintenance and milk energy yield in cows and goats. He states that "it may be accepted as experimentally established that lactating maintenance per unit live weight as a species average is about twice as high in goats as in cows, or lactating maintenance is proportional to metabolic body size as between the two species. It is equally well established that the same relation does not hold within either one of the two species. Consistently, within species lactating maintenance is proportional to a power of live weight in excess (not significant) of unity."

For cows six sets of data were available, using  $FCM_4$ , milk-energy yield for the first 8 mo. of lactation, and  $W_1$ , live weight within 31 days after parturition. "Four sets support the  $FCM_4/W_1$  philosophy almost perfectly; one set supports neither one of the two philosophies, but the metabolic body size philosophy less poorly; one set falls about half way between the two philosophies. The weight of experimental evidence as between cows distinctly supports the philosophy that  $FCM_4$  tends to be proportional to  $W_1$ ; and distinctly contradicts the metabolic body size theory of milk-energy yield ( $FCM_4$  proportional to  $kg.^{3/4}$ )."

Comparative size of Cornell dairy cows, E. G. MISNER ([*New York*] *Cornell Sta., A. E. 562 (1946), pp. 6+*).—Measurements and weights are tabulated for the purebred dairy cows of the Holsteins, Jerseys, Guernseys, Ayrshires, and Brown Swiss breeds in the Cornell main dairy barn in 1941.

The production influence of 1260 Holstein sires, E. G. MISNER ([*New York*] *Cornell Sta., A. E. 563 (1946), pp. 99+*, *illus. 8*).—This report gives the results of a study of the production influence of 1,260 Holstein-Friesian sires

for which indexes were computed up to September 30, 1942 by the Holstein-Friesian Association of America. Analysis of the rate of production data for the 18,799 daughters of these sires showed that the three-time-milking-mature-equivalent milk production of these cows was 1 percent less than their dams, the percentage of fat in the milk 1 percent more, and the total amount of fat produced per cow exactly the same as for their dams. The conclusion made from this study is that "not enough discretion is exercised in choosing sires that are mated with high producing cows. Such bulls should have a production inheritance index for milk and fat equal to that of the cows with which mated. Both should exceed breed average production by 20 percent or more."

**History and development of Holstein cattle in Frederick County, Maryland,** J. H. REMSBERG (*Middletown, Md.: Frederick County Holstein Assoc., 1946, pp. 110, about 60 illus.*)—An account of the history of the breed in this county and of the work of the Frederick County Holstein Association.

**Smältbarhetsförsök med nötkreatur.—I, Hö, cellulosa, svenska oljekakor, oljevästavfall, olika fänt sönderdelad fodersäd M. M. (Digestibility experiments with various feeds for dairy cattle),** F. JÄRL (*Lantbr. Högsk. Husdjursforsksanst. Meddel. No. 20 (1946), pp. 100; Eng. abs., pp. 95-98*).—A series of 46 digestibility experiments with bulls, cows, and heifers, using the "clue substance" method with  $\text{Cr}_2\text{O}_3$ , is reported. Coefficients are reported with variously treated cellulose feeds, linseed, rape seed, and poppy seed oil cake and mixtures of oil cakes, mustard seed oil meal, linseed straw and chaff, hemp seed offal, clover chaff, ensiled beet pulps, hays from peat and firm soils, and oats and barley ground to various degrees of fineness. English headings for all tables are provided.

**Defluorinated rock phosphate as a phosphorus supplement to the rations of dairy cattle,** T. W. GULLICKSON and F. C. OLSON. (*Minn. Expt. Sta.*). (*Jour. Dairy Sci., 29 (1946), No. 5, pp. 317-320*).—A defluorinated rock phosphate was compared with steamed bonemeal in its ability to serve as a satisfactory supplement to phosphorus-deficient rations of dairy cattle. Four grade Holstein heifers about 21 mo. of age were fed similar phosphorus-deficient basal rations during the 17-mo. period of the experiment. During the last 11 mo. two of them were fed steamed bonemeal as a supplement to their rations; the other two received equivalent additions of phosphorus from a defluorinated rock phosphate product. Total phosphorus intakes were kept slightly below the requirements of each animal. Under the conditions of the experiment no significant difference was observed between defluorinated rock phosphate and steamed bonemeal in availability of their phosphorus to dairy cattle. Animals fed the bonemeal made slightly greater gains in weight. No difference was noted in the palatability of the two supplements as fed.

**Experiments with iodinated casein on farms in England and Wales,** K. L. BLAXTER (*Jour. Agr. Sci. [England], 36 (1946), No. 2, pp. 117-150, illus. 1*).—Trials carried out on 97 widely distributed farms are reported in which paired cows were fed 20 gm. per day of iodinated casein cubes for an experimental period of 6 weeks. It was found that 4 percent of the cows refused the cubes, with an even higher rate in the Channel Island cattle.

The mean increase in daily milk yield was 5.44 lb. or 22.2 percent. This confirmed an initial assay undertaken before the trials began. The total increase in production per cow was approximately 25 gal. Heifers did not increase in yield as markedly as mature cows. When treatment stopped, yields remained elevated for several days and then dropped severely. While this drop could not be prevented, its rate was diminished by feeding addi-

tional food. The gradual reduction of the amount of iodinated casein fed, however, resulted in a more gradual return to normal.

Losses of condition, as judged by comparative score, occurred, and on some farms the losses were quite appreciable. Approximately 20 percent of the cows lost weight as judged by eye. Where cows were weighed it was found that the smaller cows lost the most weight, and that in larger-bodied cows the loss was much smaller. Feeding iodinated casein had no effect on the incidence of mastitis, lameness, or abortion. Over 6 percent of the control cows contracted mastitis, became lame, or aborted during the 8 weeks of observation. It had a significant effect on the incidence of heart abnormalities—chiefly arrhythmia—high respiratory rates, nervousness, digestive disorders such as scouring, and on the presence of symptoms suggesting iodism. Classification of the adverse symptoms associated with hyperthyroidism (with the exception of iodism symptoms) showed that their incidence was greater when the response was high.

[**Papers on milk sanitation**] (*N. Y. State Assoc. Milk Sanit., Ann. Conf., 22 (1945), pp. 7-20, 53-78, 91-104, 177-242, illus. 20*).—The following are included: Water Supplies for Milk Plants and Dairy Farms, by F. N. Thomson (pp. 7-20); Control of Milk Watering, by P. Corash (pp. 53-66); Quality Control of Milk as it Enters and Leaves the Plant, by E. A. Crawford (pp. 67-78); A Technical Quality Control Program for Dairy Plants, by C. Paley (pp. 91-102); Preliminary Report on Coliform Studies of Pasteurized Milk and Milk Products, by L. Levowitz (pp. 219-236); and Thermal Death Range of Bacteria in Milk—A New Electric Sampling Device, by F. W. Gilreath and J. E. O'Brien (pp. 237-242).

[**Abstracts of papers in dairy bacteriology**] (*Jour. Bact., 51 (1946), No. 5, pp. 575, 587, 589-590*). The following are included: Significance in Nutritional Research of Correct Identification of *Lactobacillus casei*, *L. delbrueckii*, and *L. bulgaricus*, by M. Rogosa (p. 575) (U. S. D. A.); The Viability of Dried *Lactobacillus bulgaricus* Cultures as Affected by the Temperature of the Reconstituting Fluid, by M. L. Speck and R. P. Myers (p. 587); A Survey of the Coliform Status and Suggested Standards for Coliform Control of Pasteurized Milk in a Large City, by L. Buchbinder and J. W. Fertig (pp. 589-590); and The Effects of Quality and Pasteurization of Milk on the Bacterial Flora and Quality of Cheddar Cheese, by R. P. Tittler, D. S. Geib, G. P. Sanders, H. E. Walter, O. S. Sager, and H. R. Lochry (p. 590) (U. S. D. A.).

**Studies on the effects of transport and storage on the bacteriological quality of raw milk.**—I, The reduction of methylene blue by raw milk as influenced by time and temperature of storage, V. R. SMYTHE (*Queensland Jour. Agr. Sci., 2 (1945), No. 2, pp. 128-156, illus. 7*).—Certain aspects of the milk supply of Brisbane are discussed, and trends of air temperature and raw milk quality are illustrated graphically, using data obtained by testing 95,000

milk samples over a period of 3 yr. Methylene blue reduction tests were performed on samples of raw milk collected from 20 farms in the Brisbane milk district and incubated for various periods of time up to 5 hr. at temperatures ranging from 5° to 35° C. The criterion adopted for deterioration in milk quality was the fall in reduction time, represented by the difference between the reduction time prior to incubation and the reduction time after the application of any given treatment.

The fall in reduction time produced by a rise in temperature from 20° to 35° was very marked, but was not strictly linear, the steepest fall occurring when the temperature rose from 25° to 30°. Incubation at temperatures below 20° caused an increase in the reduction time which was noticeable immediately after the initial storage period of 30 min.

At most temperatures an increase in storage time up to 5 hr. produced marked trends, which appeared to be strictly linear. The exception occurred at 10°, at which temperature no effect resulting from the period of storage was shown. A 5° increase in the duration of storage produced a progressive increase in the reduction time. All temperatures above 10° resulted in a marked fall in the reduction time as the storage period increased. The interaction of the time factor and the reduction trends due to temperature change was positive, marked, and almost linear, as was also the reciprocal action of temperature on the trends resulting from time.

As the storage temperature increased, the rate of deterioration (fall in reduction time) was greater in good quality milks than in milks of inferior quality. Furthermore, this rate of deterioration with temperature increased as storage time was prolonged, and such an added deterioration was greater when milk quality was high. No correlation was obtained between the initial quality of a milk and the effect of storage time. The shade air temperature of the day of sampling was found to exert no influence on the observed trends in the methylene blue reduction time.

**Research on rancidity in milk greatly advanced since 1726, W. L. DUNKLEY** (*Canad. Dairy and Ice Cream Jour.*, 25 (1946), No. 6, pp. 27-28, 68, 70, 72).—This is a review of the status of research on rancidity, particularly the relations of lipase to the problem.

**Causes of variation in the butterfat content of milk, V. E. GRAHAM** (*Canad. Dairy and Ice Cream Jour.*, 25 (1946), No. 6, pp. 34-36, 64, 66, illus. 2).—This discussion includes data obtained at the University of Saskatchewan, particularly as to the influences of such factors as age of the cow, season of the year, stage of lactation, differences in night and morning milk, changes in temperature, and excitement.

**The effect of route delivery on the flavor, riboflavin, and ascorbic acid content of milk, D. V. JOSEPHSON, L. H. BURCWALD, and R. B. STOLTZ.** (Ohio State Univ.). (*Jour. Dairy Sci.*, 29 (1946), No. 5, pp. 273-284).—A study of 13 milk routes in Columbus, Cleveland, St. Louis, and Boston showed fair uniformity between them with respect to the total percentage of customers who actually took in their milk within 5 min. or had it protected from light at time of delivery. Weighted averages show that approximately 70 percent of all deliveries either were taken in by the housewife within 5 min., or placed in the house, apartment, delivery box, or refrigerator by the routeman. Between the 5-min. check and the 30-min. recheck period an additional 10 percent of deliveries were taken in, and at the 60- and 90-min. rechecks about 7 and 6 percent, respectively, was removed from the doorstep. During the last hour, between the 90- and 150-min. rechecks, an additional 3 percent was taken in by the housewife. The number of customers who left their milk out more than 150 min. represented 3.3 percent of all deliveries.

Under experimental conditions of exposing milk to sunlight, the loss of ascorbic acid is extremely rapid, with only insignificant quantities remaining after 30 min. Losses of this vitamin in the shade are also quite rapid. Riboflavin losses vary depending upon the intensity of sunlight, the temperature of the milk, and the size of bottles in which the milk is exposed. Under conditions of direct sunlight exposure for extended periods of time, milk loses significant quantities of this vitamin. On the other hand, the loss of riboflavin from milk exposed to shade does not exceed 25 percent of that experienced in the direct sunlight. The photolysis of riboflavin stops when milk is removed from light while losses of ascorbic acid continue at a somewhat slower rate. The "sunlight" flavor, which develops in milk during exposure, appears to be a more critical problem than the loss of some of the riboflavin. On the basis of route studies and certain basic assumptions, it is believed that the average loss of riboflavin in all milk delivered does not exceed 3.25 percent. "It is the feeling of the writers that a program of consumer education in the care of milk can be of great value in maintaining the palatability and nutritional qualities of this important food."

**Influence of temperature on the curing of Cheddar cheese, H. C. HANSEN.** (Idaho Expt. Sta.). (*Canad. Dairy and Ice Cream Jour.*, 25 (1946), No. 6, pp. 48, 50).—In these tests, when the ripening temperature of Cheddar cheese was increased from 40° to 60° F. the loss in weight in the cheese during 6 mo. was increased from 4.44 to 8.71 percent. Cheese ripened at 40° for 6 mo. was usually criticized for being slightly acid, lacking in flavor, or flat; cheese ripened at 50° was high acid, bitter, or very slightly fruity; cheese cured at 60° was high acid, sharp, or slightly fruity. Cheese made from good milk developed more flavor in 3 mo. at 60° than did cheese cured at 40° and 50° for 6 mo., and that from good-quality raw milk developed more flavor in a shorter time than did cheese made from pasteurized milk, although it was not as uniform in flavor.

## VETERINARY MEDICINE

[**Miscellaneous observations**] (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 422-425, 429-431, illus. 1).—Descriptive accounts are given on Aujeszky's Disease in Wisconsin, by H. H. Hoyt (pp. 422-424); An Outbreak of Rabies in a Dairy Herd, by J. W. McCoy (pp. 424-425); and Leucocytic Changes in the Bovine Animal Eighteen Hours After the Subcutaneous Injection of Tuberculin, by P. D. Beamer (pp. 429-431) (Univ. Ill.).

[**Miscellaneous contributions from Onderstepoort**] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 21 (1946), No. 1, pp. 7-16, 41-55, 70-98, illus. 6).—Among the articles in this number are Further Investigations Into Immunization of Cattle Against Rinderpest, by D. T. Mitchell and P. L. le Roux (pp. 7-16); Avirulent Anthrax Vaccine, by M. Sterne (pp. 41-43), reporting results of additional tests (E. S. R., 84, p. 523) which "far surpass those obtained with the Pasteur type of spore vaccine"; Recent Investigations Into the Toxicity of Plants, etc., No. XV, by S. J. van der Walt and D. G. Steyn (pp. 45-55), which continues the series (E. S. R., 93, p. 344); and The Familial Incidence of Spontaneous Osteopetrosis gallinarum, by J. D. W. A. Coles and J. J. Bronkhorst (pp. 79-98), a study of 39 cases.

A preliminary study of the occurrence of internal parasites of animals in Mississippi, J. W. WARD. (Miss. Expt. Sta.). (*Helminthol. Soc. Wash. Proc.*, 13 (1946), No. 1, pp. 12-14).—A survey based on findings at autopsy of 349 animals, including horses and mules, cattle, sheep, hogs, chickens,

dogs, rabbits, rats, and quail, revealed at least 86 species of internal parasites. Mule colts were found to be infested with nematode parasites at as early as 15 and 26 days.

**Observations on strains of a monophasic *Salmonella* variant.** W. B. CHERRY, L. A. BARNES, and P. R. EDWARDS. (Ky. Expt. Sta. et al.). (*Jour. Bact.*, 51 (1946) No. 2, pp. 235-243).—Attention is called to a recently observed increase in the prevalence and distribution of a monophasic *Salmonella* type with the antigenic formula IV. V, XII: e,h-. The organisms have been recovered from swine, fowls, and in man from asymptomatic carriers, sporadic case, and epidemics of gastroenteritis. The strains appear to be endemic in California and Hawaii. It is suggested that the designation *S. reading* for this organism should be subjected to further scrutiny until more direct evidence of its probable diphasic ancestry is acquired. Certain of the clinical and epidemiological characteristics of infections due to this group of organisms are described.

Extensive biochemic and serologic experiments cited were designed to detect, if possible, some clue as to the derivation of the monophasic variants. Serologic results were not fruitful, but the suggestion is made that the strains may have developed as a result of a biochemic variation correlated with an antigenic alteration. Some possible further lines of approach are mentioned.

**The segregation of antigens in a bacterial culture by an undescribed form of variation.** P. R. EDWARDS. (Ky. Expt. Sta.). (*Jour. Bact.*, 51 (1946), No. 4, pp. 523-529).—*Salmonella hoimaechei* (XXIX [Vi]:z<sub>0,31</sub>) of Monteverde was found to dissociate two loss variants represented by the formulas XXIX Vi:z . . . and XXIX [Vi]:z . . . The two variants had no major H antigens in common, but in combination they possessed all the antigens of the parent culture. The variants were apparently stable types which arose through a hitherto undescribed form of variation. The possible bearing of this variation on the origin of *Salmonella* types is briefly discussed.

**A localized outbreak of *Salmonella* food poisoning apparently transmitted by a hen's egg.** M. CROWE (*Jour. Hyg. [London]*, 44 (1946), No. 5, pp. 342-345).—An outbreak of *Bacillus acitrycke* food poisoning involving 23 of 27 exposed persons is described. The vehicle was a butter extender including a raw egg.

***Salmonella* infection in man conveyed by ducks' eggs.** P. C. MALLAM and R. ALHADEFF (*Lancet [London]*, 1946, I, No. 24, pp. 887-888).—A report is given of a case of severe food poisoning in a woman who had eaten a fried duck egg. Infection with *S. typhimurium* was indicated.

**Om forgiftningsstilfeller ved bruk av kloralhydrat blandet med natriumbikarbonat mot acetonuri hos ku** (On intoxications by the use of chloral hydrate and sodium bicarbonate against acetonuria in cows, S. NESSE and A. W. BUER (*Norsk Vet. Tidsskr.*, 58 (1946), No. 5, pp. 196-200; *Eng. abs.*, p. 200).—On treating cows suffering from acetonuria with a compound consisting of chloral hydrate and sodium bicarbonate, several intoxications, partly with fatal results, have occurred. Analyses showed that both of the constituents were of a degree of purity which generally would be accepted, but it is thought that their mixing may have decomposed the chloral hydrate into a toxic compound.

**Control of brucellosis in New York State dairy herds and its relation to the milk supply.** A. WINTER (*N. Y. State Assoc. Milk Sanit., Ann. Conf.*, 22 (1945), pp. 79-90).—This deals especially with the New York State program.

**Injury as a cause of mastitis.** W. G. STEVENSON (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 4, pp. 115-116).—Instances are cited in a herd of 35 to 40 cows in which there had been over 50 percent of mastitis cases within a year. It was noted that in several animals the mucous membrane of each teat sphincter was slightly everted, and that the milking machine in use was shown by a new gage to be developing 19 in. Hg-negative pressure. Following the adjustment of the vacuum and intrammary infusion of sodium penicillin, "the serious trouble disappeared although the infection persisted."

**The isolation of diphtheroids from apparently normal cows.** E. S. FEENSTRA, F. THORP, and C. F. CLARK. (Mich. Expt. Sta.). (*North Amer. Vet.*, 27 (1946), No. 5, pp. 288-289).—Diphtheroids, some of which were similar to those isolated from cases of pyelonephritis in cows, were isolated from urine specimens and vaginas of apparently normal cows. The pathogenicity of these cultures was not established.

**Clostridium infection in range animals.** J. F. RYFF and A. M. LEE. (Wyo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 385-388).—A table is given identifying the organisms isolated in 25 cases in cattle and sheep examined for *Clostridium*.

**The probable origin of some unusually heavy infections with the common sheep hookworm (*Bunostomum trigonocephalum*).** R. T. HABERMANN. (U. S. D. A.). (*Helminthol. Sec. Wash. Proc.*, 13 (1946), No. 1, pp. 11-12).—Examination at necropsy of 89 sheep infected with *B. trigonocephalum* are reported. The average infection in one group of 34 sheep was 50.1 hookworms, and of the remaining 55, 86.8 hookworms, but two 5-year-old rams in the latter group harbored 634 and 982 hookworms, respectively. These rams had been kept for about 6 mo. with other sheep in small or overstocked quarters with deep bedding, uneaten hay, and excreta.

**Method for the recovery of *Nematodirus* adults, eggs, and larvae for experimental purposes.** C. A. V. BARKER (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 4, pp. 117-119).—A new procedure devised for obtaining uncontaminated infective material of *Nematodirus* spp. from the feces of sheep harboring several species of nematodes is described as a substitute for Kauzal's method (E. S. R., 82, p. 791), which did not yield a sufficient number of eggs in animals not heavily infected. The material was obtained from approximately the first 20 ft. of the small intestine of lambs, and the technic described always resulted in pure cultures of *Nematodirus* larvae suitable for experimental purposes.

**Studies made of lead arsenate for sheep tapeworm.** J. W. WARD and J. W. SCALES (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, p. 6).—Tests were carried on with 13 infected lambs with varying stages of diarrhea, 11 lambs receiving 0.5 gm. each of lead arsenate in a gelatin capsule and 2 receiving 1 gm. each. No parasites or tapeworm eggs were found 4 days after treatment until 5 to 12 weeks later. The diarrhea also subsided, although 2 animals required re-treatment after 5 weeks.

**Isolation of *Brucella suis* from boar's semen.** L. M. HUTCHINGS and F. N. ANDREWS. (Purdue Univ.). (*Jour. Bact.*, 50 (1945), No. 6, pp. 715-716).—Bacteriologic examination of 92 semen samples collected from six infected boars yielded *B. suis* in 63 of the samples. All six boars eliminated *B. suis* in the semen at some time during the observation period, and three of the boars continuously eliminated *B. suis* in the semen. Despite a steady decline in serum agglutination response in five of the six boars, a corresponding decline in the elimination of *B. suis* in the semen was not observed. Clinical

manifestations of brucellosis were noted in two of the six infected boars. These studies indicate that the infected boar is commonly an important reservoir of *B. suis* and that the bacteria are freely disseminated in the semen.

**Antibody response of swine to repeated vaccination with formalin-inactivated, purified swine influenza virus.** I. W. McLEAN, JR., D. BEARD, A. R. TAYLOR, D. G. SHARP, and J. W. BEARD (*Soc. Expt. Biol. and Med. Proc.*, 60 (1945), No. 1, pp. 152-159, illus. 3).—Continuing earlier work (E. S. R., 94, p. 258), it was found that the antibody response of swine to a second vaccination with formalin-inactivated swine influenza virus was greatly influenced by the period between vaccinations. Second vaccination at intervals of 1 to 4 weeks resulted in antibody titers and amounts progressively greater in direct relation to the length of the interval. In parallel higher antibody levels were maintained for longer periods in those animals receiving the second vaccination after the longer intervals. Considering the height of titer after the second vaccination, together with the rapid loss of antibody after the first injection, the interval between vaccinations optimum for maintenance of the highest antibody levels appeared to be about 3 weeks.

**Transmission of Sarcocystis to swine.** L. A. SPINDLER, H. E. ZIMMERMAN, JR., and D. S. JAQUETTE. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 18 (1946), No. 1, pp. 1-11).—A series of 16 experiments to ascertain the mode of transmission of *Sarcocystis* to swine and the clinical pathologic effects of the parasites on the host animals revealed that pigs, dogs, cats, rats, mice, and chickens are, after consuming flesh of infected swine, capable of transmitting *Sarcocystis* through elimination, with their feces and/or urine, a stage that is infective to swine, the latter becoming infected by consuming such feces or urine. In these experiments, transmission was not accomplished by feeding feces and urine eliminated by animals prior to 15 days after infected flesh had been consumed, but infection was accomplished by such feeding subsequent to 15 days.

Pigs fed feces and urine of pigs, rats, and mice that had not consumed meat did not become infected with *Sarcocystis* and showed none of the symptoms and lesions observed in infected animals. Pigs fed infected flesh did not acquire *Sarcocystis* unless they consumed their own feces and urine. The heaviest infections were found in those animals that consumed the greatest amounts of urine along with the feces.

Symptoms observed in pigs following ingestion by these animals of heavily infected flesh included vomiting, diarrhea, inappetence, weakness of the loins, and temporary posterior paralysis. Symptoms observed in pigs fed feces and urine eliminated by animals subsequent to consumption of infected flesh included unthriftiness, weakness of the loins, and temporary posterior paralysis, sometimes recurring at intervals. Pigs found at autopsy to harbor the heaviest infections were the most severely affected. In general, infections of 40 or more sarcocysts per gram of diaphragm tissue were associated with unthriftiness and stiffness of the muscles. Lesions found at autopsy of the infected animals were enlargement and paleness of the kidneys and hyperemia of the mucosa of the stomach and intestines.

**The efficacy of sodium fluoride in removing ascarids of swine.** R. W. ALLEN and L. D. JONES. (U. S. D. A. et al.). (*North Amer. Vet.*, 27 (1946), No. 6, pp. 358-360).—Continuing earlier work (E. S. R., 94, p. 521), four tests involving a total of 60 hogs were conducted to determine the efficacy of sodium fluoride as an ascaricide when administered as 1 percent by weight of the feed for 1 day. The percentage efficacies of the treatment in the four tests

were, respectively, 94.6, 95.6, 93.8, and 96.7. On the basis of the evidence at hand, the dosage used seemed to be reasonably well tolerated by the test animals.

**On the etiology of epizootic or infectious equine abortion,** M. W. HENNING (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 21 (1946), No. 1, pp. 17-10).—Continuing earlier work (E. S. R., 91, p. 75), two additional outbreaks are reported, both with a very high incidence. In the majority of the abortions studied the fetal organs were found to be extensively invaded by *Salmonella abortus-equi*, but in others this organism could not be recovered from the fetus or afterbirth. Both donkey and horse mares were found to be susceptible, donkeys being on the whole more resistant than horses. Abortion was successfully produced in both horse and donkey mares by means of (1) the oral administration of minced *S. abortus-equi* infected fetal organs, (2) intravenous inoculation of collodion membrane or Berkefeld candle filtrates of these organs, and (3) the oral administration of minced fetal organs that were culturally free from *S. abortus-equi*.

It is concluded that the primary cause of infectious equine abortion is an infecting agent that will pass either through collodion membrane, with the size of the pores 810  $\mu$ , or through Berkefeld candles. The advisability of further investigating the etiological significance of *Salmonella* encountered in epizootic diseases like calf paratyphoid and fowl typhoid is suggested.

**Equine infectious anemia in brood mares and their offspring,** C. D. STEIN and L. O. MORI. (U. S. D. A.). (*Vet. Med.*, 41 (1946), No. 8, pp. 274-278, illus. 4).—Continuing earlier work (E. S. R., 88, p. 633), transmission studies on equine infectious anemia were conducted in 1942 and 1943 with 7 susceptible brood mares and 14 colts, the latter varying in age from suckling to 3 yr. The strains of virus used were from horses experimentally infected with strains isolated from field cases occurring in Wyoming, New York, and California. The mares in the experiments were of the light type and were held in screened isolation stables with concrete floors. The colts were born and raised in an isolated breeding unit.

No definite evidence was obtained that foals may become infected with infectious anemia with typical clinical symptoms by suckling their infected dams or by close contact with their dams. In one of three cases, questionable evidence was obtained to indicate the possibility that a highly modified subclinical form of the disease may be so transmitted. This confirms previous findings that it is difficult to transmit the disease by administering infective material per os or by direct contact.

Milk from infected dams imparts no immunity to sucking colts since the latter animals are susceptible to artificial infection. Pregnant mares, when infected, may or may not abort their fetuses during febrile attacks. Full-term but weak infected colts may be foaled by infected mares. Surviving foals from infected mares may be inapparent carriers. The milk secretion and intrauterine circulation of infected mares may contain the virus. Normal suckling colts and weaned colts of different ages are as susceptible to the virus by subcutaneous injection as adult horses.

**Influence of anesthesia on experimental western equine encephalomyelitis,** S. E. SULKIN, A. GOTH, and C. ZARAFONETIS (*Science*, 104 (1946), No. 2690, pp. 53-54).—Anesthesia by ether was found to be effective in the treatment of western equine encephalomyelitis in mice. When treated with deep ether anesthesia soon after the intracerebral injection of western equine virus, only 58 percent of the mice developed the disease as compared with 92.4 percent of control animals. When anesthesia was delayed the approximate

length of the incubation period, 60 percent of the animals developed the disease as compared with 22.4 percent of the controls. In addition, ether anesthesia delayed the development of central nervous system symptoms not only when administered soon after the injection of the virus but also when administered after the disease had progressed far enough to cause objective signs of encephalitis.

**Clinical observations of "1089" poisoning.** E. J. FRICK and F. W. BOEBEL (*Vet. Med.*, 41 (1946), No. 6, pp. 196-197).—The authors conclude from a test of this new rodenticide on two horses that it appears to act primarily on the heart and is a slow-acting poison for solipeds. That it is very toxic was indicated by the small amount proving lethal—5 mg. per kilogram body weight. Heart muscle from poisoned animals transmitted the poison to other animals consuming it; apparently it has an affinity for cardiac tissue. There was practically no struggling or violence shown by the animals used in the test.

**The chemotherapy of cecal coccidiosis (*Eimeria tenella*) of chickens.**—IV, Experiments on the use of chemotherapy during the immunizing exposure of chicks, W. E. SWALES (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 393-400, illus. 2).—In this part of the series (E. S. R., 95, p. 251), the protective effect of small amounts of sulfamerazine in the feed of chicks at the time they are exposed to oocysts of *E. tenella* has been tested experimentally. One gm. of the drug per pound of dry mash, given for the first 6 days of exposure, resulted in complete protection of the chicks against fatal cecal coccidiosis, yet allowed them to develop a strong degree of resistance; when challenged in 14 days, the chicks were found to be immune. Other doses and periods of medication were tried and found to be less efficient. It is suggested that other sulforamides which include the pyrimidine-ring structure will be likewise protective.

In these experiments, the blood hemoglobin levels of the chicks were used as measurements of the degree of resistance to cecal coccidiosis. The records of the weights of the bird did not reveal any serious effect from the "chemically protected" exposure to coccidiosis.

"The practical application of this work might involve a system whereby infected chicks should be treated immediately by the sulfonamide method as previously demonstrated, and that succeeding groups of chicks on the contaminated premises should be accorded the protective treatment while they are acquiring immunity from exposure to contaminated floors."

**Effect of vitamin K deficiency on liver lipids in the chick,** J. B. FIELD and H. DAM (*Soc. Expt. Biol. and Med. Proc.*, 60 (1945), No. 1, pp. 146-148).—The hypoprothrombinemia induced in chicks by feeding a vitamin K-free diet was not significantly influenced by the addition of choline to the diet. Chicks raised on a vitamin K-free diet exhibited the typical hypoprothrombinemia, but their fibrinogen levels and total liver lipids resembled those of control chicks. The total lipids of the livers of chicks receiving synthetic diets were somewhat increased over the lipids from chicks given a natural ration, but this condition was not corrected by vitamin K.

**The status of avian pneumoencephalitis and Newcastle disease in the United States,** J. R. BEACH. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 108 (1946), No. 831, pp. 372-376).—"The purpose of this communication is to clarify the rather confusing situation created by application of the term 'avian pneumoencephalitis' on the west coast and 'Newcastle disease' on the east coast to what appears to be the same disease. To accomplish this purpose, a brief historical review of our observations and studies of the disease is presented."

**Preliminary observation on the modification of a strain of Newcastle disease virus by intracerebral passage through ducklings**, A. KOMAROV and L. GOLDSMIT (*Vet. Jour.*, 102 (1946), No. 7, pp. 212-218).—The virus used in this study was recovered from an outbreak of disease in fowls in northern Palestine characterized by respiratory-nervous symptoms and associated with over 80 percent mortality. It was maintained by serial passages in fowls and passaged intracerebrally in a series of pigeons. Apparently 9 such passages did not modify its virulence for fowls, but 14 passages in ducklings modified the strain. Fowls inoculated intradermally into the wattle with virus modified by 10 intracerebral duck passages did not develop symptoms of Newcastle disease. They were apparently immunized and resisted an inoculum of fowl virus which killed control birds in 4-5 days. Immunity to the virulent fowl virus was apparently fully established 18 days after inoculation of the birds with modified duck virus.

**Studies on pullorum disease using various rapid antigens**, W. B. DURRELL (*Canad. Jour. Compar. Med. and Vet. Sci.*, 10 (1946), No. 5, pp. 143-148).—A flock of 1,467 birds was subjected to rapid tests, using 4 antigens: (1) Regular, containing *Salmonella pullorum*, strains 4, 10, and 11; (2) variant, containing *S. pullorum*, Younie strains 2 and 296; (3) commercial, containing *S. pullorum*, Regular + Younie; and (4) commercial containing *S. pullorum*, Regular. A correlation of serological findings in a flock and bacteriological findings in the gonads of reactors revealed that regular antigen detected 92 percent, variant 78, commercial (R + Y) 100, and Commercial (R) 86 percent of the total infected birds. A case of leucosis was detected by one antigen, commercial (R + Y). This was the only evidence of possible antigenic hypersensitivity encountered.

Of the male and female gonads of reactors, 40.6 percent were found to be harboring the causative organism in its "typical" or "atypical" form. Pullorum testing prior to the hatching season is deemed of epidemiological importance. Due to antigenic difference of variant and regular strains, a mixed antigen is necessary to detect the heterologous agglutinins. The necessity for retests of infected flocks was also confirmed by this work.

"By proper interpretation of mixed antigen agglutination, use of fly control measures, incubator disinfection, and modern knowledge of poultry husbandry, losses in a poultry plant from this disease should be materially decreased in forthcoming years."

**A survey of avian salmonellosis in Great Britain**, R. F. GORDON and A. BUXTON (*Vet. Jour.*, 102 (1946), No. 7, pp. 187-206, illus. 2).—During the period 1933-44, out of a total of 6,578 groups of chicks examined 273 were infected with *Salmonella* organisms other than *S. pullorum* and *S. gallinarum*. There has been a definite increase in the occurrence of avian salmonellosis during the last 3 yr. of the period under review, and it is now second only to *S. pullorum* as a cause of fatal septicemia in young poultry. The strains of *Salmonella* organisms isolated were *S. pullorum*, *S. gallinarum*, *S. typhimurium*, *S. thompson*, *S. enteritidis*, *S. californica*, *S. bareilly*, *S. montevideo*, *S. anatum*, and *S. london*. The occurrence of *S. californica*, *S. bareilly*, *S. montevideo*, *S. london*, and *S. anatum* among poultry in Great Britain is reported for the first time. Chicks and ducklings were the species of poultry most commonly affected, but *Salmonella* organisms were also isolated from adult fowls, ducks, turkeys, turkey poults, goslings, pheasant chicks, pigeons, guinea fowls, and a sparrow.

The importance of avian salmonellosis is stressed, both from the agricultural and public health points of view. The epidemiology is discussed, and suggestions are made regarding methods of control and eradication.

**Studies on flagellates from domesticated birds.—1, The behavior of *Trichomonas gallinarum* in culture, M. W. KAY. (Ohio State Univ.). (*Jour. Expt. Zool.*, 101 (1946), No. 3, pp. 407-424, illus. 3).—This is a detailed study of this organism in culture.**

## AGRICULTURAL ENGINEERING

**Farm mechanics text and handbook, G. C. COOK, L. L. SCRANTON, and H. F. MCCOLLY (Danville, Ill.: Interstate, 1946, [rev. and enl.], pp. 744, illus. 520).—This revised and enlarged handbook (E. S. R., 75, p. 130) contains sections on woodwork and farm carpentry; painting, refinishing, and glazing; rope work; harness work; sheet metal work; farm forge work; welding; transmission of power by pulleys, belts, and shafts; farm motors; trucks and tractors; concrete work; farm buildings; farm home conveniences and sanitation; rural electrification; soil and water management; and processing farm products. The design of the book is such that it should lend itself well as a basic text for any of the usual types of farm mechanics courses.**

**Bluegrass terrace outlet channel design, D. D. SMITH. (Maine Expt. Sta. coop. U. S. D. A.). (*Agr. Engin.*, 27 (1946), No. 3, pp. 125-130, illus. 8).—Bluegrass terrace outlet channels were tested hydraulically at two growth stages, one in late May when the grass was headed out and offered its greatest resistance to flow, and the other in the late fall when only the pliable leaves shingled the channel to give a very smooth flow surface. Depth of flow varied from a fraction of an inch to about 1 ft. to give design data for the grass erect, through shingling, and when shingling was completed. Maximum average velocity of flow was limited by the density of grass that the soil can produce and maintain, the possibility of damage from rodents, cattle, and farm machinery, and the uncertainty of maintenance and weather.**

Recommendations are made for a 4 f. p. s. average velocity for the claypan prairie soils of Missouri, and for velocities up to 8 f. p. s. for soil and climate areas in which high quality sod with a density of 7 to 8 strikes per needle can be assured over a long period of time. A design chart is presented by which outlet size may be determined quickly when the maximum velocity of flow has been selected and the slope of the outlet and the expected maximum quantity of flow are known.

**General purpose soil auger, J. L. NIELSEN and B. G. WEST. (U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.]*, 8 (1946), No. 3, pp. 2, 15, illus. 1).—Results of practical experimentation with a number of types of soil augers indicate that a single-twist ship auger of  $\frac{3}{4}$ - to 1-in. diameter is the best for general purposes. In construction it is ground off and the point sharpened to an angle of about 30°. The shaft of the bit is welded to a piece of  $\frac{1}{4}$  in. heavy-duty water pipe of a length adjusted to individual needs. Materials and labor for a 6-ft. auger cost approximately \$3.**

**Sugar-beet harvester trials in Michigan in 1945, C. M. HANSEN, L. E. SMITH, and R. W. BELL (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 338-343, illus. 2).—These data for 1945 supplement those previously noted (E. S. R., 94, p. 525).**

**Mechanical field loading of sacked potatoes, W. J. PROMERSBERGER, J. C. RUSSELL, and A. MALLOW (*North Dakota Sta. Biom. Bul.*, 8 (1946), No. 5, pp. 26-31, illus. 5).—An experimental one row mechanical field loader for sacked potatoes has been designed, built, and tested under actual field conditions. The loader consists of an elevator about 11.5 ft. long mounted across a four-wheel trailer made from an old automobile chassis. The entire loading**

unit is attached to the truck being loaded by a special hitch arrangement. The elevator frame is constructed of angle iron and the conveyor is a standard conveyor chain normally used for transporting potatoes from bin to cleaning and sorting machinery with pieces of garden hose bolted crosswise at 16 in. intervals to aid in elevating the sacks. Power for the mechanism is provided by a 1¾-hp. gasoline engine connected through an automobile transmission which serves as a variable step speed reducer. When the transmission is in second gear a highly satisfactory elevator speed of about 180 ft. per minute is provided. Ordinary hand loading requires four men besides the truck driver, but mechanical loading requires only three men besides the truck driver, two men on the truck to build the load and one man that lifts the sacks from the ground to the elevator a distance of about 10 in. The loader rides on a platform just ahead of the elevator. The platform and lower end of the elevator are adjustable vertically so that they can both be set close to the ground while loading and raised for transporting. The authors report that field loading tests indicate that untrained loading crews handled more sacks per man per minute by using the machine than when loading by hand.

**Grass seed harvesting, cleaning, and processing: A summary of techniques developed by the Soil Conservation Service, U. S. Department of Agriculture, J. E. SMITH, JR. (U. S. D. A.). (*Oklahoma Sta. Bul. 295 (1946)*, pp. 96-99).**—The author presents recommendations for the selection of combine types to be used in grass seed harvesting, together with the necessary adjustments of the machines when collecting the seeds of bluestems, grammas, lovegrasses, buffalo grass, western wheatgrass, Canada wild-rye, and switchgrass. Suggested cleaning and processing operations for these grasses are also given.

**Curing bright tobacco with coal and oil, E. M. MATTHEWS, M. H. McVICKAR, and R. B. DAVIS, JR. (*Virginia Sta. Bul. 396 (1946)*, pp. 8, illus. 4).**—The authors present test comparisons of curing bright leaf tobacco using coal and oil stoker installations in barns of 500-stick capacity. Equipment and installation costs of the two systems were approximately \$200 for oil and \$325 for coal. However, average costs for fuel for curing 520 lb. of tobacco by oil was \$8.69 while for 538 lb. of tobacco by coal it was \$3.52. Normally 1½ to 2 cords of unpeeled pulpwood are required for curing an equal quantity of tobacco, and using a figure of average cost per cord of \$12 either system has a definite advantage over wood.

**A study of moisture absorption of hay when exposed to atmospheres with various moisture content, S. T. DEXTER, W. H. SHELDON, and D. ROSE (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 317-319, illus. 1).**—Samples of freshly cut and barn dried alfalfa hay were exposed to atmospheres of various selected relative humidities to observe their effect on the moisture absorption of hay. Results obtained enable the conclusion to be drawn that the relative humidity of the atmosphere need not be known with any great degree of accuracy in order to operate a mow-drier effectively. When the humidity is greater than 85 percent—which is common only during actual rain or fog—little water is evaporated from damp hay, and the function of the blower is largely to keep the hay from heating. Operation of the blower at night, when humidities are relatively high, seems to offer little possibility of depositing moisture in partly cured hay. If water is absorbed from the damp air, it will be only at the bottom of the mow and by hay that is already dry enough to keep. This partially dried air would then be capable of evaporating water from the upper, damper layers of hay. Until the top layer

of the hay has dried, the only time that it seems advisable to turn off the fan is during fog or heavy rainfall.

**Building your new house**, M. and G. CATLIN (*New York: A. A. Wyn, 1946*, pp. 267, illus. 42).—A practical treatment of the problem, based on the authors' building experiences, with their mistakes as well as their foresight candidly recorded.

**Master service manuals: Household refrigeration manual No. 1**, K. M. NEWCUM (*Detroit, Mich.: Business News Pub. Co., [1946], pp. 144, illus. 115*).—This manual contains basic information on the theory and principles of refrigeration and discusses the characteristics of the common refrigerants and the major parts of household refrigeration systems, including their adjustment, repair, and replacement. It forms the groundwork for step-by-step instructions on servicing all types of household refrigerators.

**Sewage and garbage disposal on the farm**, J. W. ROCKEY and J. W. SIMONS (*U. S. Dept. Agr., Farmers' Bul. 1950, rev. (1946), pp. 28+, illus. 17*).—This revision (E. S. R., 91, p. 204) is a guide to up-to-date methods for the sanitary disposal of sewage and other household and farm wastes. It tells how to construct and maintain satisfactory sanitary facilities, and gives special attention to the questions on sanitation asked most frequently by farm people. Where there are no specific local requirements it may be accepted as a guide to safe practice.

**Watch your step: Avoid farm accidents** (*U. S. Dept. Agr., Misc. Pub. 608 (1946), pp. 32, several illus.*).—This publication is a revision of and supersedes Miscellaneous Publication 481 (E. S. R., 86, p. 844).

## AGRICULTURAL ECONOMICS

[**Papers and notes on agricultural economics**] (*Jour. Farm Econ., 28 (1946), No. 2, pp. 413-607, about 19 illus.*).—Included are the following papers, not noted elsewhere: International Price Control Through Buffer Stocks, by O. Zaglits (pp. 413-443); Production and Welfare Objectives for American Agriculture, by T. W. Schultz (pp. 444-457); The National Food Allotment Program, by R. Schickele (pp. 515-533); Economic Functions and Units in Farm Organization, by R. J. Smith (pp. 534-542) (Univ. Calif.); and Benefits From Irrigation Under Sub-Humid Conditions, by A. Joss (pp. 543-559).

The following notes are included: National Income and Farm Income, by J. D. Black (pp. 560-562); Some Theoretical Aspects of Agricultural Parity Price Policies and National Employment, by H. R. Wellman and G. L. Mehren (pp. 563-571) (Univ. Calif.); Agricultural Prices and National Income, by A. P. Ruderman (pp. 571-575); A Quantitative Comparison of Agricultural Price Plans, by W. C. Waite (pp. 575-587) (Univ. Minn.); An Approach to the Determination of Intraseasonal Shifting of Demand, by G. L. Mehren and H. E. Erdman (pp. 587-596) (Univ. Calif.); Tailored Credit for Land Improvements, by J. D. Black (pp. 596-604); and Agricultural Economists' Views on Farm Price Policy (pp. 604-607), a summarization of the views of 305 agricultural economists in a survey by the committee on parity concept of the American Farm Economic Association.

**Foreign Agriculture [June-July 1946]** (*U. S. Dept. Agr., Foreign Agr., 10 (1946), No. 6-7, pp. 81-104, illus. 5*).—Included are the following articles: Structure of Agricultural Prices and Wages in Colombia, by J. A. Hopkins (pp. 82-96), the general objective of which is to appraise the general, overall economic efficiency of Colombian agriculture; Policy Measures and Food Production in Venezuela, by O. Moore (pp. 96-104), in which the high-cost

economy of the country, foreign-trade control, agricultural-production policy, etc., are discussed; and Soviet Aid to Agricultural Specialists, by S. Goodstein (p. 104), describing the terms of the decree issued by the Soviet Government on November 2, 1945, for the improvement of the material welfare of agricultural specialists in the Soviet Union.

**Input-output relationships in fattening cattle,** A. G. NELSON. (U. S. D. A.). (*Jour. Farm Econ.*, 28 (1946), No. 2, pp. 495-514, illus. 5).—"The purpose of this paper is (1) to set up and analyze input-output relationships throughout the fattening period of calves, yearlings, and 2-year-old feeders; (2) to point out significant relationships; and (3) to indicate the usefulness of this analysis in the development of necessary food programs and as the foundation for an analysis of costs and returns relationships.

"The efficiency with which feed is utilized in the production of food and food constituents at various stages in the fattening period is indicated by an analysis of relationships in data on feed consumption, gain in live weight, slaughter grade, dressing percentage and body composition during the fattening period."

Charts show for the three types of animals throughout the fattening period the relations of live weight and of weights of chemically determined constituents of the edible body to total quantity of feed consumed; gain of live weight to 100 lb. of total digestible nutrients consumed; gain in edible body nutrients per 100 lb. of total digestible nutrients consumed; and gain in edible crude protein and edible ether extract per 100 lb. of total digestible nutrients consumed. Tables show (1) the estimated percentage increase in live weight, edible body and edible nutrients on choice feeder steers fattened to average good and average choice slaughter grades, and (2) comparison of edible product and food nutrients produced per 1,000 feed units by fattening cattle and other livestock. The charts and tables, together with others, have been presented and discussed in U. S. D. A. Technical Bulletin 900 (E. S. R., 94, p. 387).

**Feed consumption and the production of pork and lard,** L. J. ATKINSON and J. W. KLEIN (*U. S. Dept. Agr., Tech. Bul. 917* (1946), pp. 21+, illus. 4).—The same basic data for 12 feeding experiments in five Corn Belt States are used as in Technical Bulletin 894 (E. S. R., 93, p. 788). The present study explores further the relationship between feed consumption and the output of different constituent elements of the hog carcass. The purpose of the bulletin "is to show the relationships between consumption of feed by hogs and output of pork and lard. These relationships are analyzed for three sets of assumptions: (1) The total number of hogs is assumed to be fixed. The feed consumption is then related to the output of live weight, dressed weight, and edible pork and lard resulting from hogs marketed at specified weights and resulting from specified changes in marketing weight. (2) The supply of feed is assumed to be fixed, whereas the number of hogs varies. The feed consumption is related to the output of pork and lard at specified weights and to indicated changes in marketing weights. (3) One of the two joint products is assumed to be fixed while the other varies. (a) The output of pork is assumed to be fixed while the number of hogs varies. Changes in feed consumption are related to changes in output of lard between specified points as the marketing weight of hogs changes. (b) The output of lard is assumed to be fixed while the number of hogs varies. Changes in feed consumption are related to changes in output of pork between specified points as the marketing weight of hogs changes." The data are analyzed and discussed under the following headings: Feed consumption and output of live

weight, dressed weight, and edible product, with sections on chemical composition of the carcass and physical composition—input-output relationship; feed consumption and joint output of standardized pork and residual fat from a fixed number of hogs, and alternative output combinations of standardized pork and residual fat with a fixed feed supply; feed consumption and output of pork and fat taken separately; and meaning and interpretation of adjusted additional output. An appendix includes the formulas used in the analysis of the composition of the individual hog, the tables on which the charts in the bulletin are based, and the glossary of terms used in a more or less specialized sense. A bibliography is included.

**Cost of producing sheep in southwestern Utah in 1945.** D. A. BROADBENT (*Farm and Home Sci. [Utah Sta.], 7 (1946), No. 2, pp. 7-8, 16*).—A table is included comparing the different expenses, receipts, and profits for breeding ewes 1939-41 and 1945. The data were obtained in a detailed study of 60 ranches for 1939-41 and 17 of the same ranches for 1945. The reasons for changes in the various items are discussed. The total expenses and receipts per ewe were \$5.55 and \$7.93 respectively in 1939-41 and \$10.70 and \$10.31 respectively in 1945.

**Cost of producing butterfat in Utah.** G. T. BLANCH and G. Q. BATEMAN. (Coop. U. S. D. A.). (*Farm and Home Sci. [Utah Sta.], 7 (1946), No. 2, pp. 6, 16, 17, 18-19*).—A table is included and discussed comparing the costs per cow and per pound in producing butterfat in 1937-39 and the estimated costs in 1945. The 1937-39 costs were obtained in a study of 452 cost-of-production farms supplying milk to Ogden (E. S. R., 89, p. 737). The estimates for 1945 are based on farm prices of feed and labor from price reports of the U. S. D. A. Bureau of Agricultural Economics, and a study of 45 dairy farms in Summit County made by the Utah Agricultural Extension Service and other current general and economic data. Other tables show the amounts and costs per cow of different feeds fed during the two periods; the quantity of feeds normally required and the feed costs per pound of butterfat, and different levels of butterfat production per cow per year; the cost of man labor per pound of butterfat at varying levels of production, and costs of man labor per hour; and the production and feed costs for cows in Utah dairy herd improvement associations, 1944-45.

The net costs of producing butterfat per cow and per pound were \$107.16 and 42.4 ct., respectively in 1937-39 and \$219.20 and 82.7 ct. in 1945. Costs for feed per cow was \$51.58 and \$118.30, respectively, in the two periods and costs of man labor \$40.61 and \$81.00. The average number of man hours labor per cow and price per hour used were 163 hr. and 25 ct. in 1937-39, and 135 hr. and 60 ct. in 1945.

**Economic aspects of canning peas in Wisconsin.** W. W. WILCOX and J. B. BOWDITCH. (Coop. U. S. D. A.). (*Wisconsin Sta. Res. Bul. 158 (1945), pp. 17+, illus. 4*).—Two hundred and sixteen representative canning-pea growers in the eastern, Spencer-loam, and northwest areas of the State were interviewed regarding production practices, yields, costs, and returns; and 27 companies regarding services furnished growers, comparative yields and quality of company- and farmer-grown peas, and average returns of farmer growers. Analyses are made of the trends in acreages of canning peas in Wisconsin and the United States; the yields per acre in Wisconsin of peas, oats, and corn, 1919-45; the costs and returns, 1944, for canning peas in the three areas studied, with a table showing the physical and money costs; and the competitive position of canning peas and oats in the State. The factors important for high yields of peas, the reduction of feed production

due to growing of peas, canners' services to growers, company- v. farmer-grown peas, and the farmers' comments on the advantages and disadvantages of growing canning peas are discussed.

The average yields and net returns per acre, including return to land, in the three areas were: Eastern, 1,918 lb. and \$40.25; Spencer-loam, 1,661 lb. and \$22.80; and northwest, 1,414 lb. and \$21.15. In each area the farmers with the highest yields found canning peas a profitable crop, but those with yields below the average were usually dissatisfied with returns. Oat yields in all sections during 1939-43 would have had to be about 30 bu. per acre higher to equal the returns obtained from canning peas. The yields of oats required to equal the returns from 1,200- to 2,400-lb. yields of peas were 37 to 38, and 108 to 110 bu., respectively.

**A credit study on 167 tobacco farms, Puerto Rico, 1939-40, J. O. MORALES and S. L. DESCARTES** (*Puerto Rico Univ. Sta. Bul.* 69 (1946), pp. 54+, illus. 2; *Span. abs.*, pp. 52-54).—The study is based on records for 167 farms taken in the intensive tobacco producing area of Puerto Rico. Additional information was obtained from 21 lending agencies. Analyses are made of the financial conditions of the farmers; the amounts and sources of long-time credit; and of short-time loans for production of tobacco and other purposes, and the purposes for which the loans were used. The number of months the loans were outstanding, the seasonal distribution of loans, the collateral required, the methods of charging interest, the credit costs, and the attitude of borrowers toward the lenders are discussed. Analyses are made of the amount advanced per cuerda, per hundred-weight of tobacco, and per value of crop; the relation between credit advanced per cuerda and size of business, and yield per cuerda; between amount advanced and value of crop and size of the tobacco plantings; and between cuerda of tobacco to the amount advanced per cuerda.

The average assets of the farmers were \$3,707, and the average liabilities on June 30, 1940, were \$1,251, consisting of mortgages averaging \$549, production credit \$488, store credit \$65, other liabilities \$147, and unpaid balances on preview production loans \$2. Forty-nine of the farms were mortgaged, the average mortgage being \$1,667. Twenty-seven of the loans were from the Federal Land Bank and Land Bank Commissioner and 21 from individuals. There were 321 short-term loans, totaling \$97,017, of which amount 86 percent was for tobacco production, 6 percent for other crops, and 8 percent for personal accounts. Of the 185 loans totaling \$83,386 for tobacco production costs, 80 totaling \$63,144 were made by dealer-lenders. Loans were outstanding an average of 9.4 mo. The tobacco production credit outstanding at the time of liquidation constituted 73 percent of the value of the crop. Other short-term personal debts brought the total borrowings to 80 percent of the value of the crop.

**Price tendencies in farm land of high and low productivity** (*Ohio Sta. Bul.* 659 (1945), pp. 12-13, illus. 1).—This analysis covering more than 1,700 tracts of farm real estate sold in the period of January 1941 to July 1944 depicts the tendency in an inflationary period for the price of land of low-productive capacity to advance relatively faster than the price of land of high-productive capacity. That this tendency existed during the last period of rising land prices has been emphasized by the observation that the majority of farms involved in financial distress during the late 1920's and early 1930's were lands of poor productive capacity purchased a few years previously when prices were inflated. The general level of farm real estate prices in Ohio advanced from an index value of 80 as of March 1941 to 111 in

March 1944, a change of 39 percent. As indicated by this study, there was a price advance of 28 percent for the better and of 58 percent for the poorer lands.

**Farming systems and practices, red soil area, Eastern Highland Rim, Tennessee. 1944.** S. W. ATKINS and C. C. MANTLE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 200 (1946), pp. 58+, illus. 4*).—"The primary purpose of this report is to make available information on land use, systems of farming, sizes of farms, crop and livestock management, and other related data describing important phases of the agriculture of this area." Information was obtained largely through interviews regarding 84 commercial and 25 semicommercial (self-sufficing and part-time) farms in Putnam, White, and Warren Counties. In the analysis the commercial farms are grouped as general, dairy, and beef farms, and also on the basis of size.

[**Economic land classification in Virginia counties**] (*Virginia Sta. Buls. 391 (1946), pp. 10, illus. 1; 392, pp. 8, illus. 1*).—These bulletins continue the series (E. S. R., 95, p. 582). The counties covered are: Bulletin 391, Hanover, by G. W. Patteson and A. J. Harris; and 392, Grayson, by G. W. Patteson and Z. M. K. Fulton, Jr.

**Long-time adjustments in forage land utilization in the northeast region, V. L. HURLBURT.** (U. S. D. A.). (*Jour. Farm Econ., 28 (1946), No. 2, pp. 476-494, illus. 4*).—"The purpose of this report is to analyze from the standpoint of land requirements the direction and the nature of the adjustments that appear imminent, rather than to determine the most desirable level of production for the region." The region studied included the New England States and New York, Pennsylvania, New Jersey, Delaware, and Maryland. The problem situation in and economic aspects of forage land utilization and the significance of the adjustments to the land economy are discussed.

**The economy of small farms in Wisconsin, W. W. WILCOX.** (Univ. Wis.). (*Jour. Farm Econ., 28 (1946), No. 2, pp. 458-475, illus. 3*).—The study is based on a sample of 150 farms with 20 to 39 acres, and of 150 with 40 to 59 acres of cropland in 25 townships representative of the better farm areas (eastern, western, and southern) of the State. Among the phases discussed are decline in farm numbers, 1936-44; productiveness of soils; intensiveness and diversification in use of croplands; use of labor saving machinery; buildings; incomes earned and causes of variations; the human side of small farms; family characteristics; the financial situation; and occupational experience and plans of the small farm operators.

**Labor saving through farm job analysis.—II. Hay harvesting, R. M. CARTER** (*Vermont Sta. Bul. 531 (1946), pp. 52, illus. 19*).—This is a study of the time used in performing different operations in the jobs of cutting, raking, bunching, loading, hauling to storage, unloading, and mowing away hay with different types of equipment and power. It is based on observations on approximately 140 commercial dairy farms visited in 1944 and 1945. On about half of the farms detailed time studies were made of all observed operations, roads and fields were measured, and the hay handled was weighed. Charts show for the individual farms the time required for different operations in doing the different jobs in handling 1 ton of hay, using different methods and types of equipment and power. Tables accompanying the charts show for each job and operation the average time required and the time required on the farms using the least and the most time. The facts presented in the charts and tables are discussed. "The facts presented are not intended in any way to indicate general averages, but rather a summary record of ob-

servations made at given times and places." A section—the farm operator's problem—discusses the utilization of the data obtained in the study, job inter-relationships, job-method combinations, the importance of farm equipment, and the importance of knowing how to do a job. Appendixes analyze the average, the highest, and the lowest time costs in getting 500 lb. of hay out of the mow and feeding it; give estimates of costs of farm equipment required for various job-method combinations; and describe the construction and operating costs of a buck rake built and operated by the station, and the two-piece hay racks in use in the State.

This study continues the series (E. S. R., 90, p. 262).

**Marketing the 1944 Wyoming wool clip under the Commodity Credit Corporation Purchase Plan**, J. L. VAN HORN and H. H. HULBERT (*U. S. Dept. Agr., Farm Credit Admin., Misc. Rpt. 98 (1946), pp. 29 +, illus. 1*).—Under Food Distribution Order 50, effective April 25, 1943, the Commodity Credit Corporation became the sole purchaser of all domestically produced wool, and was authorized to purchase the domestic clip at the ceiling prices established by the Office of Price Administration in the fall of 1942. The administration of the purchase program by the Corporation is described. Tables are included and discussed for the 1944 Wyoming wool clip, showing among other items, the types of sales, grades and types of wool, distribution of the volume by areas of the State and grades, gross ranch prices, handling charges, sales results by area and grade, shrinkage and yield by grades, tonnage received by handlers, and similar items.

**Causes of changes in the price of potatoes**, G. E. BRANDOW (*Pennsylvania Sta., Jour. Ser. Paper 1331 (1946), pp. 23 +, illus. 9*).—The period considered is from 1921, when the price collapse following World War I had halted, to 1940, the year before the United States entered World War II. The general price level and the price of potatoes; the relation of potato supply to price; the explained and unexplained changes in the price of potatoes from year to year; seasonal variation in potato prices; the demand for potatoes; and the margins between prices received by farmers and paid by consumers are analyzed and discussed. Potato prices in the postwar period are briefly discussed.

**Wholesale marketing of Irish potatoes in Knoxville, Tennessee**, B. H. LUEBKE and C. C. MANTLE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 199 (1946), pp. 29 +, illus. 16*).—Among the subjects discussed are: The volume, total and seasonal, of potatoes handled by wholesale dealers; the origin, total and seasonal, of the potatoes; seasonal variation in volume handled; origin of truck receipts; varieties and grades handled; method of buying; average and seasonal wholesale prices; storage by wholesalers; and the wholesale margin in handling.

**Retailing and consumption of Irish potatoes in Knoxville**, B. H. LUEBKE and C. C. MANTLE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 201 (1946), pp. 21 +, illus. 4*).—Part 1, retailing of potatoes (pp. 1-8), is based on data obtained from a sample of 20 grocery stores and covers annual sales; frequency, size, and channels of purchases; consumers' preferences as to varieties; price mark-up by stores; seasonal consumption; etc. Part 2, consumption of Irish potatoes by food establishments (pp. 8-15), is based on a sample of 40 of the approximately 175 public and semipublic places where food is served in the city. Annual purchases; source, frequency, and size of purchases; varieties served; variety preferences for different preparations; substitutes, etc., are discussed.

**The fall shortage of milk:** A problem in price adjustment, L. SPENCER and H. A. LUKE ([*New York*] *Cornell Sta.*, A. E. 559 (1946), pp. 31+, illus. 6).—The fall shortage of milk, especially in New York State, the factors that are responsible for the shortage, the seasonal pattern of milk production, price incentives for fall production and ways of producing such incentives, etc., are discussed. Proposed adjustments for the period April 1946 to June 1947 are suggested in the prices of dairy products and in butterfat subsidy payments on a national basis, and in the prices of fluid milk and cream in the New York milkshed, and comparisons are made with the period April 1945 to June 1946.

**Should cheese be priced on a solids and butterfat basis?** W. V. PRICE and A. B. EREKSON (*Natl. Butter and Cheese Jour.*, 37 (1946), No. 7, pp. 40, 41, 86, 88, 90-92).—These two articles discuss the problems of pricing cheese. Each approaches the subject in a different way. The article by Price (pp. 40, 86, 88) (Univ. Wis.) includes a general formula for the "fat and dry basis" price by which tables can be built up to show the value of any cheese on the "fat and dry basis" for any combination of butter and cheese prices. The article by Erekson (pp. 41, 90-92) presents three methods for calculating the increased value of high fat cheese.

**Apple quality and its effect on price and rate of sale,** G. E. BLANCH ([*New York*] *Cornell Sta. Bul.* 826 (1946), pp. 50, illus. 5).—Data were obtained on 401 lots of apples at the G. L. F. Mid-Hudson Fruit Auction at Milton, N. Y., from September 17 to October 2, 1942, and 303 lots offered for sale in 112 retail stores in Syracuse and Buffalo, N. Y., between October 1942 and January 1943. Data from the auction sales are analyzed and discussed under the headings: Variation in price and reasons for price differences—variety, size, grade, and quality defects; and those for the retail store sales under the following headings: Types of influence of quality factors; variations in price and rate of sale; factors affecting price and rate of sale—"store characteristics" and elements of quality; retail margins; and source of supply. The adequacy of grade standards is also discussed.

In the auction study, the average price paid for the varieties studied (McIntosh, Cortland, Rhode Island Greening, and Northern Spy) was 71 ct. per bushel, the total range being from 20 ct. to \$1.70. A premium (net) of 30 ct. per bushel was paid for good color over poor color. The most seriously bruised lots were discounted 28 ct. per bushel over the least affected lots. Lots most seriously affected by apple scab were discounted 23 ct. per bushel over lots free of fungus. Red bug injury where abundant decreased the price 24 ct. per bushel. The price differential between lots free from codling moth stings and the most seriously affected lots was 21 ct. per bushel. Stage of maturity, except for apples reaching the ripe stage, did not have an important effect on price. "As the number of defects increased, prices decreased regularly (disregarding the fact that some defects have a greater influence on price than do others). Over the entire range from 2.4 to 8.5 defects, the decrease in price averaged 8 1/3 ct. per defect."

The price of apples at the time of visit to the retail stores varied from 2 to 15 ct. per pound, averaging 6.2 ct. The daily rate of sale from individual lots varied from 0 to 300 lb. An average of slightly more than 1/2 bu. was sold per lot. Increase in size of store, as measured by sale of a selected group of products, caused apple sales to increase rapidly but not in proportion to the increase in size of store. McIntosh, Cortland, Northern Spy, Rhode Island Greening, and local Delicious were the fastest-selling and highest-priced varieties. "The third of the lots with the best color was 11 percent higher

in price than the third with the poorest color, but the rate of sale was double. The total premium for best color was about the same as at the auction. . . . The least clean lots were priced 0.8 ct. per pound lower than the clean lots, and the rate of sale was 10 lb. less. No lot offered for sale was free of bruised fruit. The influence of this defect was primarily on rate of sale, for retailers did not reduce price as the fruit became more bruised after entering the store. Lots seriously affected with apple scab were discounted 0.8 ct. per pound and the rate of sale depressed 1/3 bu. per day. When decay was encountered the selling price was reduced 1/3 ct. per pound and the rate of sale about 35 percent. "Fruit loses condition when in a store at relatively high temperatures and low humidity. The surface eventually becomes wrinkled and the flesh spongy, a condition commonly called shrivel. This condition reduced price somewhat. It reduced the rate of sale by a large amount that became increasingly serious from day to day." The retailers' average margin was 63 percent of the retail price, or approximately 2.3 ct. per pound. Retailers tended to add about the same mark-up in cents regardless of the amount paid for the fruit.

**Postwar purchase and improvement plans of farmers, A. M. AHALT, S. H. DEVAULT, and L. E. FLECH** (*Maryland Sta. Bul. A40 (1945), pp. 87-123 +, illus. 13*).—On the basis of records obtained by questionnaires and personal interviews covering 1,084 farms in six counties representative of the type-of-farming areas of the State, analyses are made of the estimated expenditures during the first two postwar years (1946 and 1947) for farm equipment, construction and repair of buildings, general service improvements (fencing, electricity, and water, heating, and sewage systems), and household equipment. Other analyses are made of the farmers' plans for financing the expenditures and of the postwar labor opportunities in the State. Analyses are made for the State as a whole, for each type-of-farming area, and by size-of-farm groups. The sample used included 9.9 percent of the 10,943 farms in the six counties with 10 acres or over, according to the U. S. Census of 1940. The estimated expenditures for the State are based on 36,610 farms that had 10 acres or over. Some of the findings were:

The estimated cost of purchases and improvements planned during the first two postwar years is \$72,670,000, or \$1,990 per farm of 10 or more acres. The estimated expenditures per farm for the four classes of improvements are: Farm equipment \$1,010, buildings \$750, general service \$110, and household equipment \$120. Approximately 52 percent of the farmers plan to purchase some type of motor vehicle, and about 30 percent plan to purchase a tractor. New construction and repair of dwellings will account for one-third of all anticipated building expenditures, with new dairy barns and repairs on old barns a close second to dwellings. Construction of new buildings will account for 70 percent and repairs for 30 percent of the building expenditures. Expenditures for fencing and electricity will be greater than for any of the other general service improvements. Refrigerators, bathroom fixtures, and washing machines are expected to account for 73 percent of the expenditures for household equipment. Estimated expenditures per farm range from \$1,455 to \$3,016 for the different type-of-farming areas, and from \$1,159 for farms of 10 to 49 acres to \$3,016 for farms of 180 or more acres. The farmers plan to finance 55 percent of the postwar expenditures from income earned during the immediate postwar period, 34 percent from accumulated savings, and 11 percent from loans. It is expected that 23,600 regular farm laborers will be employed in the postwar period, as compared with 18,200 in 1940 and 11,900 in 1944. The number of family workers, exclusive

of operators, decreased from 26,400 in 1940 to 25,300 in 1944. A total of 9,400 farms are operated with the help of farmers' sons. Approximately 4,700 farmers were planning to enter into sharing or partnership arrangements with their sons if they returned to the farm after the war.

## RURAL SOCIOLOGY

**War relocation of subsistence farmers** (*Ohio Sta. Bul. 659* (1945), p. 12).—From November 1942 through March 1943 the U. S. D. A. Farm Security Administration, in cooperation with the U. S. Employment Service and the Ohio State University, aided in the relocation of workers and their families from comparatively unproductive farms in eastern Kentucky to Ohio for training and placement as farm laborers. Of the 316 workers transported from Kentucky to Ohio who were included in the study, 214 were hired by Ohio farmers. In August 1943, 5 to 9 mo. after their employment, it was found that only 101 remained in their original farm jobs in Ohio. The majority of these who moved went back to Kentucky or into some nonfarm employment. It was found that the relocation of people from the hills of Kentucky to the commercial and mechanized farming areas of Ohio involved the workers and their families in difficult problems of personal and social adjustment. The workers most successful in making the readjustment included those in the age range of 20-40 yr. who had had at least eight grades of schooling.

**Farmer co-operation to meet emergency labor needs during the war years**, S. T. KIMBALL (*Michigan Sta. Quart. Bul.*, 28 (1946), No. 4, pp. 320-325).—The author tells how the farm labor problem was met in Shiawassee County, Mich., during the war years.

**American cooperation, 1942-1945** (*Philadelphia: Amer. Inst. Coop.*, 1945, pp. 432+).—This is an extensive collection of papers summarizing the problems of farm cooperatives during the war period and how they were met.

**Twelve out of every 100 farm youths not enrolled in school: Rural schools face a major problem**, S. C. MAYO (*Res. and Farming* [*North Carolina Sta.*], 4 (1946), *Prog. Rpt.* 3, pp. 5-6, 10, *illus.* 2).—At the time of the 1940 census there were in North Carolina 76,227 young people 8-16 yr. of age out of school. Twelve percent, a larger proportion than in any other residence class, of each 100 farm boys and girls were not associated with the school system, and rural areas had more than their proportionate share of these out-of-school youths. Rural-farm areas of the State were especially heavily weighted—52.9 percent of the population 8-16 yr. of age were living on farms, but 59 percent of the out-of-school youths were on farms, including 13.8 percent of the boys and 9.8 percent of the girls. The proportion of nonwhite youth out of school was larger than in the white in all residence classes, but in rural-farm areas it included 16.4 percent of the nonwhite boys 8-16 yr. on farms. At age 16, half of the rural farm nonwhite boys were in school and half were out.

**[Studies of health and human resources in Ohio]** (*Ohio Sta. Bul. 659* (1945), pp. 13-14).—Death rates among infants, children, youths, and very old people were generally higher in rural areas than in the cities where health services and facilities are more adequate. Death rates were highest of all in the economically and socially disadvantaged rural areas. Doctors, dentists, and hospitals, as well as other health services and facilities, were heavily concentrated in the large cities and were least adequate where levels of living were lowest. Before the war, the Ohio counties with the eight largest cities had 160 doctors, 70 dentists, and 383 general hospital beds for

each 100,000 of the population. The remainder of the State, including most of the rural population, had only 91 doctors, 39 dentists, and 159 general hospital beds per 100,000 people. The most disadvantaged rural area in Ohio had only 75 doctors, 31 dentists, and 113 general hospital beds per 100,000 people. A much larger proportion of rural than of urban doctors and dentists were aged men who had passed the peak of their efficiency as practitioners.

**The development and financing of local governmental institutions in nine Vermont towns,** R. M. CARTER (*Vermont Sta. Bul.* 529 (1946), pp. 66+, *illus.* 13).—This is the second in a series of four bulletins covering the land use and local institutions in nine of the commercial agricultural towns in Vermont (E. S. R., 94, p. 824). Governmental institutions in nine Vermont towns were analyzed for a 12-mo. period to determine local geographic sources of incomes and allocations of expenditures, mainly for the year 1939. Over 80 percent of the tax base in these towns was made up of real estate, more than half of which was within village limits. In the open country, property values per square mile declined from land class to land class. While total maintenance costs for all highways are divided about equally between town and State, local officials have responsibility for disbursing about two-thirds of all funds. For the towns as a whole, taxes raised on village property were used to support highways in rural areas, expenses in every land class being greater than average taxes assessed for that purpose. A few large schools provided for the needs of the villages, while many small, and sometimes inadequate, schools were required for rural children. The proportion of rural families needing relief was related to average physical conditions within a land class, ranging from 1 percent of all families in land class 1, to 12 percent in land class 4. The major demand for assistance, however, was from village families. When taxes collected were allocated to the various areas on the basis of their needs, indications were that villages required about 52 percent of the total; land class 2, 24 percent; land class 1, 12 percent; land class 5, 10 percent; and land class 4, 2 percent. Indebtedness amounted to \$40 on each \$1,000 of assessed valuation, or approximately one year's tax revenue at the current rate. The tax resources of the villages are sufficient to meet the costs of these services and also to provide a small margin for use in rural areas. In the open country, only in land class 1 is revenue collected in excess of outlays.

**Postwar revenues for rural public services in Maryland,** W. P. WALKER and S. H. DEVAULT (*Maryland Sta. Bul.* A41 (1946), pp. 125-154+, *illus.* 3).—The purposes of this study were to examine the adequacy of State and local tax resources; to review basic principles and policies underlying tax support of major rural governmental services; and to suggest changes in law or policy which will produce more equitable taxation and result in more comparable public services for rural people. The basic data were obtained from reports of the Comptroller of Maryland, Maryland State Tax Commission, State Department of Education, State Roads Commission, State Board of Welfare, Boards of County Commissioners, U. S. Bureau of Internal Revenue, and U. S. Bureau of the Census. The first section describes the services and amounts of the tax revenues of the State and the different counties. The second part—Modification of Tax Structure—calls attention to the tax procedure in State income taxation and property taxation, "which seems inconsistent with other declared State policies and which produces inequalities in tax burdens, with special reference to income and property taxation and rural public services." The third section—Functional Aspects of Tax Rev-

enue System—discusses the three governmental functions—public education, county roads, and public welfare—which account for the major part of State and local expenditures, and how “their proper support depends upon a State policy which results in balancing the needs of each and levying and distributing equitable taxes for their support.”

**A case study in township zoning**, S. T. KIMBALL (*Michigan Sta. Quart. Bul.*, 20 (1946), No. 4, pp. 253-269).—This is an analysis of objections to zoning in a suburban residential neighborhood.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Report of cooperative extension work in agriculture and home economics, 1945**, M. L. WILSON (*U. S. Dept. Agr., Ext. Serv. Rpt.*, 1946, pp. 43).—This annual report (E. S. R., 93, p. 93) of the Director of the Extension Service for the year ended June 30, 1945, deals briefly with the activities in different fields of about 9,000 extension workers. The usual statistics are included as to the number of counties with county extension agents, sources of funds, and expenditures in the different States, Alaska, Hawaii, and Puerto Rico.

**Teaching grade labeling**, J. V. COLES. (Calif. Expt. Sta.). (*Jour. Home Econ.*, 38 (1946), No. 4, pp. 211-212).—This paper points out pertinent points for impartially presenting grade labeling to consumer or student groups. The study of grade labeling may be satisfactorily approached as a problem itself, or in connection with different groups of commodities. It involves a study of how it affects consumers, producers, and distributors, including its relation to and its effects on brands and advertising.

## FOODS — HUMAN NUTRITION

**Foods used by Filipinos in Hawaii**, C. D. MILLER, L. LOUIS, and K. YANAZAWA (*Hawaii Sta. Bul.* 98 (1946), pp. 20, illus. 17).—This well illustrated bulletin, written primarily for the use of teachers, extension agents, public health nurses, dietitians, and others interested in the welfare of Filipinos in Hawaii, is based chiefly upon a study of foods and dietary habits of Filipinos whose incomes are low, but its dietary and food expenditure recommendations should also apply to those financially well situated. Brief discussion is devoted to the emigration of various dialect groups from the Philippines to Hawaii and their present distribution in the Territory, and to a comparison of the diet and health of Filipinos in the Philippines and in Hawaii. Detailed consideration is given to 22 food products much used by Filipinos in Hawaii, their use and nutritive value being discussed and data on their proximate mineral (Ca, P, Fe) and vitamin (vitamin A, thiamine, ascorbic acid) content being reported. Other foods used by the Filipinos are listed, and the place of rice, corn, and wheat in the Filipino diet is considered. Recommendations for improving the diet of the Filipinos in Hawaii are given, and Filipino methods of food preparation are suggested by the recipes presented for the use of the various foods analyzed. A short technical section describes the preparation of the samples and the methods of chemical analyses and vitamin assays employed. There are 59 literature citations.

**Ways to use vegetables in Hawaii**, H. Y. LIND, M. L. BARTOW, and C. D. MILLER (*Hawaii Sta. Bul.* 97 (1946), pp. 110).—This bulletin, planned especially for the homemaker, gives simple and concise directions based on the findings of recent scientific research for the selection and preparation of

about 40 vegetables available in Hawaii. Concerning each vegetable there are notes on nutritive values, points to consider in selection, recipes for preparing in a number of appetizing ways, and specific directions for preserving the maximum nutritive value. A brief discussion on the contribution which vegetables in general make to the well-planned diet, the general principles involved in storing and cooking vegetables, and the selection and care of utensils used in vegetable cookery precede the sections which include recipes. A convenient tabulation shows which vegetables are to be regarded as excellent, good, fair, and poor sources of vitamin A, thiamine, and ascorbic acid; the classification is based on the vitamin values of the cooked vegetables, except in the case of cucumbers, lettuce, tomatoes, and water cress.

**Organoleptic tests pertaining to apples and pears.** W. D. EATEN. (Mich. Expt. Sta.). (*Food Res.*, 11 (1946), No. 1, pp. 84-91, illus. 2; abs. in *Mich. Sta. Quart. Bul.*, 28 (1946), No. 4, p. 361).—Tests were made on Delicious and Grimes Golden varieties of apples held in cold storage at 33° F., room temperature (72°), and at various times of the day. Judges scored the apples on the basis of their desirability and juiciness. The author summarizes the findings: "This study has shown that the average mature person likes cold apples and pears better than those served at room temperature. The average mature person also believes that fruits held at 33° are juicier than similar fruits held at about 72°. A large majority of layman judges are consistent in their decisions concerning desirability of the fruits examined. . . . Cold fruits of inferior quality are considered by the average person to be about as good, if not better than, fruits of superior quality at room temperature. One time of the day is about as good as any other time for testing apples."

**Ascorbic acid prevents frozen peaches from browning.** J. G. WOODROOF (*Georgia Sta. Press Bul* 567 (1946), p. [1]).—This mimeographed report presents two home formulas and two commercial formulas for packing Elberta peaches for freezing. Ascorbic acid is recommended for preventing browning, and citric acid is suggested for stabilizing the ascorbic acid. Lemon juice may be substituted for the citric acid, serving also to enhance the color and flavor of the peaches.

**Community canning centers.** (U. S. Dept. Agr., Misc. Pub. 544, rev. (1946), pp. 86 |, illus. 66). This publication, a revision of an earlier edition (E. S. R., 91, p. 355), provides an additional section on the establishment and operation of small canning centers using gas burners. Slight modifications are made in some of the techniques described earlier in order to conform with State laws on food, safety, health, and sanitation.

**Changing pattern of food preparation of small town families in Mississippi.** D. DICKINS (*Mississippi Sta. Bul.* 445 (1945), pp. 51 |).—This study of changing food preparation practices and of the factors underlying these changes was based on data gathered by personal interviews with 1,158 white and Negro families living in four small Mississippi towns, two in the Delta and two in the Short Leaf Pine area. A study of the findings reported in detail in this bulletin indicated wide variation between white and Negro families in use and preparation practices; it appeared also that variations in towns of different soil areas were due in some part to differences in home food production programs but more to differences in socioeconomic status of the families as indicated by differences in monthly rent or rental value.

One method used in studying changes in food preparation involved a study of new dishes tried during the year. Among the white families, those in the intermediate housing groups (\$7.51 to \$20.00 and \$20.01 to \$40.00 monthly rental value) tried new dishes more often and averaged more new dishes than

those in the very low or the high rental groups. Of the total number of new dishes tried, relatively more of those tried in families of lower housing value were desserts than in the case of those tried in higher housing value families; the latter group tried relatively more salads than did the former group. Thirteen percent of all the new dishes tried were also new foods. Eighteen percent of the new foods tried were rated as poor or fair, while only 3 percent of the new combinations of familiar foods were thus rated. Sixty percent of the dishes receiving fair or poor rating were vegetable dishes. New dishes were tried most often upon the recommendation of friends, although homemakers in the higher housing value groups sometimes tried recipes from magazines, newspapers, and cookbooks; in the lower housing value groups advertisements were relatively more often the source of new recipe suggestions. Suggestions for new dishes tried by the Negro woman often came from the white woman.

Another approach to the study of changing food preparation patterns was through comparison of the methods of preparing 12 commonly used foods in the family and in the parental home. With the exception of cooked cabbage and slaw, it was found that the majority of the homemakers in all groups prepared these foods as they had learned to do in the parental home. Families of higher housing values made relatively more changes than families of lower housing values. Negro families made somewhat fewer changes than white families. In most cases, change in the method of preparation was attributed to family preference.

Findings of the study suggest (1) that any improved practices in food preparation will be brought about through the recommendation of friends or local leaders who could recommend adoption of new practices on the basis of their own personal experience; (2) that recommended changes in preparation practices must result in palatable foods acceptable to the family members; (3) that improved practices must be introduced through application to familiar rather than new foods; (4) that better time scheduling and change in tastes perpetuated since childhood must be stressed in attempts to introduce shorter cooking times for improved vegetable cookery; (5) that home economists who attempt to influence the food preparation pattern of families in the community need to cooperate with local groups and should cooperate with food and equipment manufacturers, advertising agencies, and publishers of women's magazines in order to assure technically sound suggestions from these sources; and (6) that home economists should cash in on good changes wrought by the war in perpetuating improved practices in food preparation.

**Simple meals are time savers.** D. DICKINS (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, p. 2).—This is a report of 80 white and 80 Negro homemakers' records, which shows the relationship of the number of dishes served at breakfast, dinner, supper, and the average time spent in preparation and clearing away the meals. When the number of dishes served was the same, there was little difference in time expenditures in clearing away in white and Negro groups, but time expenditures in preparation were greater for the Negroes, due probably to their poorer facilities for food preparation.

**The utilization of d-amino acids by man.**—V, Histidine. A. A. ALBANESE, J. E. FRANKSTON, and V. IRBY (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 441-447, illus. 2).—A detailed description is given of the colorimetric procedure used in the estimation of histidine in urine. Measurements are made of the intensity of the red color produced by the diazo test following the destruction of interfering phenols by acid permanganate.

Adult humans were fed 0.01 mole of *l*(-)-histidine·HCl·H<sub>2</sub>O and *dl*-histidine·HCl·H<sub>2</sub>O. Within 9 hr. after administration of the *dl*-histidine, a total excess of urinary histidine was excreted which was approximately equal to the amount of *d* component so ingested. Based on this observation and the optical activity of an isolated fraction of this excess histidine, the authors adduce that *d*(+)-histidine is poorly utilized by man.

**The effect of dietary proteins and amino acids on liver fat,** J. M. R. BEVERIDGE, C. C. LUCAS, and M. K. O'GRADY (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 505-518, illus. 2).—Elaborating upon their previous studies (E. S. R., 95, p. 793), the authors have studied the lipotropic effects of various diets. Fourteen different high-fat (40 percent beef drippings) diets were studied. Casein and/or gelatin provided protein in amounts equal to 35 or 40 percent of the total diet. The casein content ranged from 10 to 40 percent. The methionine and cystine contents of all the diets were maintained constant. Other essential amino acids were added in varying concentrations to the test diets.

Tabulated results indicate that the apparently superior lipotropic effect of free methionine over an equal quantity bound in casein (at casein levels below 22 percent) was obliterated when the quantities of the essential amino acids in the two diets under comparison were made approximately equal. Thus the lipotropic effect of a diet is determined not only by its content of sulfur-containing amino acids but also by its adequacy in other respects.

The authors conclude that the lipotropic activity of a protein is determined not only by its methionine and cystine contents, but also by the nature and quantity of the sulfur-free essential amino acids in the protein. These amino acids act indirectly; through their well-known influence on growth and maintenance they influence the formation of new tissue, thus modifying the amount of methionine left available for lipotropic action.

"Some evidence is presented for the existence in casein of a lipotropic factor other than methionine. Indirect evidence suggests that tyrosine may be involved."

A discussion is presented analyzing the discrepancies which arose in previous attempts to account for the lipotropic effect of casein. Fifty-three references are cited.

**The inability of human or beef globin to support normal hematopoiesis in the rat without added isoleucine,** J. M. ORTEN, J. E. BOURQUE, and A. U. ORTEN (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 435-440).—Rats were fed a synthetic diet containing casein (22.5 percent), purified human globin (19.6 percent), or beef globin (19.6 percent) as the sole source of protein. Both globins failed to support growth and normal hemoglobin formation.

Supplementation of either type of globin with isoleucine was sufficient to produce maintenance of a normal concentration of hemoglobin in the blood. Subsequent removal of isoleucine was followed by the development of a mild to severe anemia and death of the animal. These observations indicate that isoleucine is necessary for normal blood formation in the rat.

**Corneal vascularization in rats on a tryptophane deficient diet,** A. A. ALBANESE (*Science*, 101 (1945), No. 2633, p. 619).—On a tryptophan-deficient diet, weanling rats developed corneal vascularization and cataracts. Although this diet was considered adequate in riboflavin, additional supplements of riboflavin amounting to 120γ per day were fed to a second group but no amelioration of the symptoms occurred.

The addition of tryptophan to the deficient diet resulted in rapid gain in weight, complete recovery from the corneal lesions, and partial disappear-

ance of the cataracts. Similar results occurred when the riboflavin supplements were discontinued in the second group and tryptophan supplementation was initiated.

**Growth and lipotropism.**—I, The dietary requirements of methionine, cystine, and choline, C. R. TREADWELL (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 601–607).—Rats were fed a basal diet containing 40 percent lard, 15.4 percent casein (vitamin free), 3.2 percent arachin, 5 percent salt mixture, 2 percent Cellu flour, and 34.4 percent glucose. Supplements of the necessary vitamins were added. The methionine and cystine contents were 500 mg. and 100 mg. per 100 gm. diet, respectively. Varying amounts of methionine, cystine, and choline were then added to this basal diet.

Results showed that the total methionine requirement of rats receiving a choline-free diet was approximately 1,200 mg. per 100 gm. of diet. This total was differentiated into a growth requirement of 600 mg. and a lipotropic requirement of 600 mg.

Amounts of cystine greater than 100 mg. per 100 gm. of diet did not exhibit any effect on the growth rate or any antilipotropic activity; 600 mg. of cystine excited a slight lipotropic effect when the methionine content was 500 mg.

When the basal diet was supplemented with 100 or 200 mg. of choline per 100 gm. of diet, there was no significant change in the growth rate.

The rats' need for lipotropic factors may be met by choline, methionine, betaine, or other substances capable of donating methyl groups. When these substances are present in the diet, no methionine is required for lipotropism. If the diet lacks these other lipotropic factors, then the methionine needed for lipotropic action is a high proportion of the total methionine requirement.

**The influence of age and diet on the lipid composition of the rat**, H. H. WILLIAMS, H. GALBRAITH, M. KAUCHER, and I. G. MACY (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 463–474).—Newborn rats and animals 15, 45, and 70 days old were assayed for their lipid constituents. The whole bodies of the rats were ground and dried and determination made of the following lipid fractions: Phospholipide (cephalin, lecithin, and sphingomyelin), free and combined cholesterol, cerebroside, and neutral fat. Experiments were also carried out using 22-day-old rats as controls and litter mates which had ingested 3,000 calories (in an average of 66 days) of an adequate high-fat or low-fat diet.

The importance of separating the lipides of the body into (1) neutral, or storage lipid, fat and (2) essential, or structural, lipid is stressed. Alterations in the essential lipid composition of the body during growth were not reflected in the changes occurring in total lipid composition; the latter reflected the variations in the neutral fat which composed the largest portion (50 to 90 percent) of the total fat.

The essential lipid pattern changed appreciably during growth and development. The concentrations of phospholipide and free cholesterol decreased, whereas those of cerebroside and cholesterol esters increased.

Diets in which 40 to 70 percent of the calories were derived from fat had no influence on the essential lipid composition of the body. A diet in which less than 10 percent of the calories was furnished by fat produced an apparently significant alteration. On the latter diet, the rats contained less cerebroside and free cholesterol and more esterified cholesterol.

**The effect of growth on the lipid composition of rat tissues**, H. H. WILLIAMS, H. GALBRAITH, M. KAUCHER, E. Z. MOYER, A. J. RICHARDS, and I. G. MACY (*Jour. Biol. Chem.*, 161 (1945), No. 2, pp. 475–484).—As part of the above

study, certain animals were sacrificed for a study of lipid distribution in the tissues (brain, heart, kidney, lung, testes, liver, thymus, spleen, and skeletal muscle). All of the tissues showed an increase in essential lipid content during growth, primarily due to an increase of phospholipide. The other components of the essential lipid, cerebrosides and cholesterol, varied independently, not only with respect to each other but also to the total.

In these experiments, the fundamental change in lipid composition common to all the tissues studied appeared to be a quantitative increase in cephalin concentration. Specific changes in the various organs during growth were an increase in cerebrosides in testes and in skeletal muscle and a decrease in cardiac muscle; a decrease in free cholesterol and sphingomyelin in both skeletal and cardiac muscle; and an increase in sphingomyelin in kidney, lung and spleen. All essential lipid components except lecithin and cholesterol esters showed a marked increase in the brain during growth.

The probable relationships of these changes in lipid composition and pattern among the various tissues to the structural and functional growth of the tissue are discussed.

**The effect of tocopherol and of fat on the resistance of rats to anoxic anoxia.** E. L. HOVE, K. HICKMAN, and P. L. HARRIS (*Arch. Biochem.*, 8 (1945), No. 3, pp. 395-404, illus. 1).—Various groups of rats previously maintained on a stock diet were fed a stock diet or vitamin E-deficient diets containing 0 to 12 percent lard. Anoxia was produced in the rats by gradual decompression for 15 min. to about 185 mm. Hg.

Results showed that natural mixed tocopherols given orally in physiological quantities to adult rats resulted in a time of survival to anoxic anoxia greater (+89 percent) than that of controls on a vitamin E-free, low fat diet. The effectiveness of tocopherol was decreased (to about +31 percent) when the diet contained fat at a 12 percent level.

Fat in the diet decreased survival time of rats under conditions of anoxia. This was thought to be due to a decrease in the animals' R. Q.

The injection of large single doses of *d*- $\alpha$ -tocopheryl phosphate greatly increased the time of survival to anoxia of guinea pigs on a rabbit chow diet, but had no effect on rats.

**Influence of the calcium intake level upon the complete life cycle of the albino rat.** H. L. CAMPBELL and H. C. SHERMAN (*Amer. Jour. Physiol.*, 144 (1945), No. 5, pp. 717-719).—Continuing the studies of Campbell et al. (*E. S. R.*, 92, p. 298) the life histories of 72 female and 48 male rats on each of three levels of calcium have been investigated. Calcium levels were 0.34, 0.48, and 0.64 percent of the air-dry food mixture fed. The basal diet was considered as optimal as possible in all other respects.

The data on number of young reared, duration of reproductive life, and length of life are tabulated. The authors conclude from the results obtained that, under the favorable dietary conditions of the experiment, "the three levels of calcium intake here studied resulted in essentially equally good records throughout the life histories of the experimental animals. Thus with a diet sufficiently good in other respects, the range of optimal calcium intake extended from 0.34 to at least 0.64 percent of the air-dry food mixture."

**Factors influencing the destructive effects of acidic beverages on the teeth of white rats and hamsters.** R. A. GORTNER, JR., J. S. RESTARSKI, J. G. BIERI, and C. M. MCCAY (*Arch. Biochem.*, 8 (1945), No. 3, pp. 405-414, illus. 4).—The studies of Restarski et al. (*E. S. R.*, 94, p. 271) have been confirmed and elaborated. Solutions of citric, lactic, phosphoric, and sulfuric acids at pH 2.6 were found to attack the teeth of rats in different degrees.

Citric and lactic acid solutions and a synthetic lemonade caused severe damage to lower molars and had little effect on the uppers.

The addition of 10 percent sucrose, glucose, or maltose increased the tooth-destructive properties of phosphoric acid solutions in vivo. Lactose, on the contrary, had no such effect. The decalcifying properties of citric, lactic and sulfuric acid solutions were not influenced by the addition of 10 percent sucrose.

Experiments with hamsters receiving citric acid solutions containing 1, 5, 10, and 20 p. p. m. of fluorine (as sodium fluoride) produced results comparable with those reported previously for the rat. In most instances, fluorine provided partial protection against tooth destruction by acid. The differential action of citric acid in vivo on the upper v. lower molars of rats was not observed in the hamster.

Studies in vitro on the decalcification of pulverized human enamel by various acids, both alone and in the presence of sucrose or saccharin, yielded results differing from those noted in vivo with the rat. Phosphoric acid-sucrose caused greater tooth destruction in vivo than did citric acid, but this situation was reversed in vitro. Also, in vitro sucrose failed to increase the decalcification of enamel by phosphoric acid. When fluoride was added to the acid solutions, however, the enamel solubility in vitro was lowered 14 to 30 percent.

**The excretion of ascorbic acid and dehydroascorbic acid in sweat and urine under different environmental conditions,** J. B. SHIELDS, B. C. JOHNSON, T. S. HAMILTON, and H. H. MITCHELL. (Univ. Ill.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 351-356).—Four young adult male subjects were tested in a controlled environment with temperature and humidity so regulated as to provide comfortable, hot dry, and hot moist conditions. Ascorbic acid assays were made by the method of Roe and Kuether (E. S. R., 90, p. 297), as the indophenol method was found to give false results when rubber materials were used in collecting the sweat. Results showed that when no extra vitamin C was added to the diet, excretion of ascorbic acid and dehydroascorbic acid averaged, respectively, 33 $\gamma$  and 34 $\gamma$  per 100 cc. of sweat. After a dose of 500 mg. of ascorbic acid/day had been fed for 7 days, the ascorbic acid excretion became 0 in 3 out of 4 subjects, while the dehydroascorbic acid excretion averaged 107 $\gamma$ /100 cc. sweat.

"The data indicate an increased skin excretion of dehydroascorbic acid following ascorbic acid dosage, and a decreased excretion of ascorbic acid. The average total 24 hr. excretion of dehydroascorbic acid varied from 0.8 mg. under 'comfortable' conditions to 2.7 mg. under conditions inducing profuse sweating throughout the day."

Urinary excretion of ascorbic acid on a constant ascorbic acid intake was markedly increased under hot moist environmental conditions as compared to either comfortable or to hot dry conditions.

**The occurrence of inositol and of p-aminobenzoic acid in sweat,** B. C. JOHNSON, H. H. MITCHELL, and T. S. HAMILTON. (Univ. Ill.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 357-360).—The same hot moist and comfortable environmental conditions described above were used, and the sweat and urine of the subjects were assayed for inositol (I) and p-aminobenzoic (PAB) acid by microbiological methods.

The concentrations of I and PAB acid in sweat averaged, respectively, 21 and 0.24 $\gamma$ /100 cc. Under comfortable and hot moist conditions, the average hourly excretion of I in sweat was 0.027 and 0.118 mg., respectively. Corresponding average urinary losses were 0.626 and 0.494 mg./hr.

The effect of environmental temperature and potassium iodide supplementation on the excretion of iodine by normal human subjects, H. SPECTOR, H. H. MITCHELL, and T. S. HAMILTON. (Univ. Ill.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 137-143).—The micromethod of Spector and Hamilton (*E. S. R.*, 94, p. 580) was used in estimating the iodine excretion. Under hot moist conditions (38.3° dry bulb, 69 percent relative humidity), the concentration of iodine in undiluted sweat was 0.95 $\gamma$  per 100 cc. A 2-mg. dose of KI increased the average concentration to 3.18 $\gamma$  per 100 cc., while 14 daily doses of 2 mg. of KI did not produce any significant additional increase.

Profuse sweating (averaging about 677 gm. per hour) increases dermal losses of iodine at high levels of iodine intake (2,200 $\gamma$  per day, KI dosage), but at low levels (700 $\gamma$  per day) no consistent change was observed. The effect of a sweating environment on urinary output of iodine was variable. No evidence was obtained that a sweating environment will increase iodine requirements.

At least three-fourths of the total iodine lost from the body was excreted through the urine. When the iodine intake was increased with KI supplementation, most of the increased excretion of iodine was found in the urine.

The fecal excretion of iodine was greater under hot moist than under comfortable conditions at high levels of iodine intake. No differences were apparent at the basal levels. Iodine dosage raised the fecal output of iodine significantly in a hot moist, but not in a comfortable, environment.

The effect of pantothenic acid dosage and environmental temperature and humidity upon the dermal and renal excretion of pantothenic acid, H. SPECTOR, T. S. HAMILTON, and H. H. MITCHELL. (Univ. Ill.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 145-152).—Dermal excretions for a period of 8 hr. and urines for 24 hr. were collected from five young men under comfortable and under hot moist conditions, both with and without pantothenic acid dosage. These collections were analyzed for pantothenic acid by the method of Krehl et al. (*E. S. R.*, 90, p. 727), with *Lactobacillus arabinosus* as the test organism.

Daily dosage with about 18 mg. of pantothenic acid did not alter the pantothenic acid concentration of undiluted sweat, which averaged 3.8 $\gamma$  per 100 cc.

An increase in the relative humidity from 65 to 92 percent with a dry bulb temperature of about 32.22° C. produced an increase of 176 percent in the average net loss of body weight and a concomitant increase of 221 percent in the average dermal excretion of pantothenic acid.

On an unsupplemented diet the average dermal excretion of pantothenic acid was 5.1 $\gamma$  per hour under comfortable conditions, but under hot moist conditions this was increased to 27.7 $\gamma$  per hour. An increase in the urinary excretion of pantothenic acid was also noted under hot moist conditions, even though the volume of urine under these conditions was only about one-half to one-third of the volume under comfortable conditions. Under hot moist conditions 31 percent of an 18 mg. dose of pantothenic acid was recovered in the urine.

The combined urinary and dermal excretion of pantothenic acid under hot moist conditions on a normal diet averaged 5.66 mg. per day in 1 week and 3.84 mg. per day in another. This was 11.6 percent greater than the excretion under comfortable conditions. The authors conclude that the data suggest, but do not prove, that the total excretion of pantothenic acid in urine and sweat may be increased under conditions of profuse sweating induced by environmental conditions.

**Nutritive value of canned foods.**—[XIII], Influence of temperature and time of storage on vitamin contents, N. B. GUERRANT, M. G. VAVICH, and R. A. DUTCHER. (Pa. State Col.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1240-1243, illus. 5).—Continuing this series, noted on page 623, the effect of storage on the vitamin content of tomato juice, green lima beans, and whole-kernel yellow corn has been studied at 30° to 110° F. over a 365-day period. The vitamin content of each food was affected adversely by prolonged storage at the higher temperatures. The amount of vitamins retained varied with the type of product and the particular vitamin. Both time and temperature affected the retention of ascorbic acid. When corn and lima beans were stored at higher temperatures for long periods, reducing substances were formed which interfered with ascorbic acid determinations unless special procedures were adopted. Temperature of storage had a limited effect on carotene retention but a marked effect on thiamine retention. Riboflavin retention was not seriously affected by any of the conditions employed. Pantothenic acid retention was affected adversely by both time and temperature of storage, the temperature effect being most significant. Storage at extremely high temperatures (110°) for relatively short periods resulted in marked losses of vitamins, especially ascorbic acid and thiamine. These data emphasize the necessity of storing canned foods under the most favorable conditions in order to retain maximum vitamin content. It is suggested that the vitamin content of canned foods can be preserved most effectively at storage temperatures ranging from just above the freezing point of the respective food to approximately 42°.

**Studies on vitamin content of canned pineapple**, A. J. HAAGEN-SMIT, A. G. R. STRICKLAND, C. E. P. JEFFREYS, and J. G. KIRCHNER (*Food Res.*, 11 (1946), No. 2, pp. 142-147).—Vitamin A (carotene), thiamine, riboflavin, ascorbic acid, pantothenic acid, and *p*-aminobenzoic acid were determined on five types of commercially canned pineapple. Vitamin A, thiamine, riboflavin, and ascorbic acid were assayed biologically as well as by recommended chemical or physicochemical procedures. The other vitamins were assayed microbiologically. Assays were made on winter- and summer-packed fruit, and on the solid and liquid portion of the content of the can, as well as on the fresh fruit.

Results showed lower values for vitamin A (approximately 50 percent) and thiamine (approximately 20 percent) in the winter-packed fruit, higher values (approximately 30 percent in the solid portion) for ascorbic acid and pantothenic acid in the winter-packed fruit, and no significant changes in riboflavin content due to seasonal variation.

Ascorbic acid values for fresh pineapple ranged from 70 to 142 International Units, with an average of 100 I. U./100 gm. Thiamine in fresh pineapple ranged from 25.3 to 42.0 I. U., with an average of 35 I. U./100 gm.

**The effects of fertilizer treatments, curing, storage, and cooking on the carotene and ascorbic acid content of sweetpotatoes**, M. SPEIRS, H. L. COCHRAN, W. J. PETERSON, F. W. SHERWOOD, and J. G. WEAVER (*Georgia and North Carolina Stas., South. Coop. Ser. Bul. 3* (1945), pp. 31, illus. 1).—This bulletin, the third in a series of Southern cooperative bulletins (E. S. R., 93, p. 643), presents a detailed technical report on work conducted cooperatively by experiment station nutrition workers in Georgia and North Carolina. Materials and methods, including the growing of the crop from sweetpotato plants obtained from a common source, the harvesting of the crop, curing and storage of the roots, the cooking and sampling procedures, and the methods of chemical analysis and statistical analysis, are discussed in detail.

Experimental results, tabulated and discussed, indicate that "sweetpotatoes of the Unit I Porto Rico variety retained their original carotene content from time of harvest through curing and 6 mo. of storage under controlled conditions. A slight loss of carotene, 9.9 percent, occurred on boiling whole roots, and a greater loss, 23.9 percent, resulted from baking. The ascorbic acid content of this variety at harvest was reduced 17 percent by curing. A progressive loss of ascorbic acid, about 6 percent of the original content in a month, occurred during storage. Neither boiling nor baking whole sweetpotatoes caused any loss of ascorbic acid. Fertilization with various combinations of N, P, K, and Ca had relatively little effect on the moisture, carotene, or ascorbic acid content of this variety of sweetpotato. Significant variations in composition were found between individual sweetpotatoes and also between root, center, and stem transverse sections."

**The antioxygenic synergism of tocopherol and rice bran extract in the preservation of carotene.** R. M. TOMARELLI and P. GYORGY (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 367-379, illus. 5).—Vitamin A-deficient rats were fed a suboptimum dose of carotene in linoleic acid. Certain groups received additional supplements of mixed tocopherols (T) in linoleic acid and/or a rice bran extract (RB). Rats fed carotene  $\pm$  RB failed to gain weight and died in approximately 16-20 days. With the addition of T to the carotene supplements, the rats gained an average of 9.2 gm./week; in the presence of T + RB, the gain was 10.9 gm./week.

In vitro tests showed that carotene in linoleic acid is oxidized or destroyed within 24 hr. The addition of RB alone had no effect on this destruction. The addition of T alone extended the time required for 50 percent destruction of carotene to 2 days. With the addition of both RB and T, approximately 60 percent of the carotene remained after 8 days.

This same antioxidant synergistic effect was noted on solutions of carotene in cottonseed or soybean oil. While RB alone partially stabilized the solutions of carotene (due to the presence of natural tocopherol in these oils), the simultaneous addition of T and RB improved the stability of the carotene in both cottonseed and soybean oil.

**The vitamin A activity of neo- $\beta$ -carotene U and its steric rearrangement in the digestive tract of rats.** A. R. KEMMERER and G. S. FRAPS. (*Tex. Expt. Sta.*). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 305-309).—Biological rat growth tests were carried out with samples of neo- $\beta$ -carotene U extracted from alfalfa, or prepared by iodine catalyses of  $\beta$ -carotene. Results showed that the vitamin A activity of neo- $\beta$ -carotene U approximated 25 percent of that of all trans- $\beta$ -carotene.

Tests were made on the intestinal contents of the rats 6 hr. after administration of neo- $\beta$ -carotene U, and on the rat feces. Results indicated that the vitamin A activity found was due to a steric rearrangement in the digestive tract of the rat of part of the neo- $\beta$ -carotene U into  $\beta$ -carotene and neo- $\beta$ -carotene B.

**Preserve vitamin B<sub>1</sub> in lima beans.** L. MCWHIRTER (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, p. 7).—This is a brief report of a study on the loss of vitamin B<sub>1</sub> during the cooking of Henderson Bush variety lima beans. The raw beans at the green stage of maturity contained 0.256 mg. of vitamin B<sub>1</sub> per 100 gm. of beans; when matured to the white (but not dry) stage of maturity, the raw beans contained 0.270 mg. per 100 gm. Cooking experiments in which the raw beans were slowly dropped into twice their weight of boiling water and cooked for 30 min. showed that the green limas lost only 2.3 percent of their original vitamin B<sub>1</sub> content but that the

mature white beans lost 17 percent during this cooking period; when the cooking period was extended to 3 hr. the losses were 41 and 37 percent, respectively.

**The microbiological activity of dl-oxybiotin and related compounds.** T. WINNICK, K. HOFMANN, F. J. PILGRIM, and A. E. AXELROD (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 405-410, illus. 1).—The relative activity of dl-oxybiotin (in terms of d-biotin) was tested by comparing the amount required to produce half maximum growth of the following four organisms: (1) *Lactobacillus arabinosus*, (2) *L. casei*, (3) *Saccharomyces cerevisiae*, and (4) *Rhizobium trifolii*. On a percentage bases, the activity of dl-oxybiotin was 50, 40, 25, and 15 percent for the four organisms, respectively.

The hydrolysis of the urea ring in oxybiotin resulted in almost complete inactivation of the compound for *S. cerevisiae* and *L. arabinosus*. Replacement of the carboxyl group in oxybiotin by a primary alcohol group decreased the activity for these two organisms to 1/300 that of the parent substance.

Inhibition experiments with avidin demonstrate that oxybiotin, its methyl ester, and its pentanol derivative all combined with avidin in approximately the same molecular proportions as does biotin. The diamino derivative of oxybiotin was not inhibited by avidin.

**Human biotin metabolism on various levels of biotin intake.** J. GARDNER, H. T. PARSONS, and W. H. PETERSON. (Wis. Expt. Sta.). (*Arch. Biochem.*, 8 (1945), No. 3, pp. 339-348).—Studies were made of the biotin metabolism of 10 college women who consumed a low-, moderate-, and high-biotin diet, and the moderate diet supplemented with 50 $\gamma$  and 100 $\gamma$  of biotin as the methyl ester. These diets contained from 9 $\gamma$  to 171 $\gamma$  of biotin daily.

An increase in dietary biotin intake from 9 $\gamma$  to 33 $\gamma$  failed to cause a rise in urinary biotin, but the fecal biotin increased 40 percent. When 171 $\gamma$  of dietary biotin were ingested, the urinary biotin increased to more than 5 times that excreted on the low- or moderate-biotin diet, while the fecal biotin increased 80 percent over that of the low-biotin diet.

Total biotin output averaged 9, 3, and 1.5 times the dietary intake for the low-, moderate-, and high-biotin diets, respectively, indicating biotin synthesis with relatively less synthesis taking place on the high-biotin diet.

When 50 $\gamma$  of biotin were added to the moderate-biotin diet, a maximum of 30 percent of the additional biotin was accounted for in the urine. This occurred on the third or fourth day after the beginning of the biotin feeding.

When 100 $\gamma$  of biotin were ingested, a maximum of 72 percent was accounted for in the urine. The rise in excretion continued for the entire 6 days of higher intake. No change in fecal biotin occurred when either 50 $\gamma$  or 100 $\gamma$  biotin were fed. The water-soluble biotin in dried feces varied from 2-15 percent of the fecal biotin. An increase in measurable biotin occurred when a water extract of feces was acid hydrolyzed.

Twenty-five or 50 $\gamma$  of biotin given with breakfast and dinner were excreted promptly, a large portion of the additional biotin being found in the urine within 6 hr. after ingestion.

**Nutritive value of fish from Michigan waters.**—I, Nicotinic acid of lake herring, carp, common suckers, and burbot, J. F. KLOCKE, T. PORTER, P. I. TACK, E. LEFFLER, N. S. HENRY, and R. NITCHALS. (Mich. Expt. Sta.). (*Food Res.*, 11 (1946), No. 2, pp. 179-186).—Lake herring (*Leucichthys artedii*), common suckers (*Catostomus c. commersoni*), carp (*Cyprinus carpio*), and burbot (*Lota lota maculosa*) were assayed at different seasons of the year over a 2-yr. period. Assays were made on fresh, frozen, smoked, and baked samples. A modification of the chemical method of Dann and Handler

(E. S. R., 87, p. 14) was used for the determination of nicotinic acid. Preliminary extraction studies with various enzyme preparations (takadiastase and papain, and polidase) as well as concentrated acid or alkali digestion indicated the best results were obtained by digesting with polidase at pH 7.0 for 16-18 hr. at 45° C.

The results are tabulated and show that lake herring from Saginaw Bay had an average of 55, 31, and 23  $\mu$ g. of nicotinic acid per gram of tissue in November 1943 and June and November 1944, respectively. Green Bay herring contained an average of 27  $\mu$ g. per gram in February and 23  $\mu$ g. per gram in June and November. The highly significant differences in nicotinic acid content could only be explained by the effect of seasonal or environmental conditions.

Common suckers contained an average of 13 and 11  $\mu$ g. of nicotinic acid per gram of tissue in March and October, respectively. In May and October carp had 15  $\mu$ g. per gram, burbot averaged 16  $\mu$ g. per gram, carp roe had values of 13  $\mu$ g. of nicotinic acid per gram, while herring roe contained 6  $\mu$ g. per gram. Wide individual variation occurred in each species studied.

Freezing and subsequent storage for 2½ to 3 mo. caused insignificant loss of nicotinic acid in carp, common suckers, and two groups of lake herring. Herring analyzed after 9 months' storage retained an average of 67 percent of the initial nicotinic acid present.

When fresh or frozen fish were baked no loss of nicotinic acid was noted. Smoked herring and common suckers retained 66 and 72 percent, respectively, of nicotinic acid in the processed fish.

The nicotinic acid content of fresh, frozen, and smoked lake herring is considered comparable to the nicotinic acid content of lean meat. The content of carp, burbot, and common suckers is slightly lower.

**The fate of N-methylnicotinamide in man,** W. A. PERLZWEIG and J. W. HUFF (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 417-418).—Data are briefly presented to explain steps in the transformation niacin in the body. The excretion of  $F_1$  is considered to represent the resultant of the rates of two or more metabolic reactions involving niacin: (1) Its methylation to  $F_2$  and (2) the subsequent conversion of  $F_2$  to some as yet unknown product(s).

**Riboflavin content of tropical foods,** C. F. ASENJO, H. GARCIA DE LA NOCEDA, and P. SERRANO. (P. R. Univ. Expt. Sta. et al.). (*Food Res.*, 11 (1946), No. 2, pp. 137-141).—Determinations were made on the riboflavin content of 93 foods either produced or commonly consumed in Puerto Rico and the neighboring islands. The microbiological method of Snell and Strong (E. S. R., 82, p. 587) and its modification by Strong and Carpenter (E. S. R., 89, p. 514) were used.

The data are tabulated by food groups: Cereals and cereal products, fruits, root vegetables, beans, greens, seeds, other vegetables, dairy products, eggs, fish, meat and miscellaneous. The English and Spanish common names, as well as the scientific names, are listed, and brief descriptions of the samples and indication of the number of samples tested are also included in the tabulation. Riboflavin values are presented in terms of micrograms per 100 gm. of fresh edible portion; maximum, minimum, and average values are given.

**The effect of varied thiamine intake on the growth of rats in tropical environment,** A. O. EDISON, R. H. SILBER, and D. M. TENNENT (*Amer. Jour. Physiol.*, 144 (1945), No. 5, pp. 643-651, illus. 3).—Experiments were conducted on rats maintained at 90° F. and 70 percent relative humidity (tropical environment) and 72° and 50 percent relative humidity (temperate

environment). A purified diet was fed, supplemented with adequate vitamins, including thiamine at a concentration of 0.2  $\mu$ g. per 100 gm. of diet.

In the first experiment the rats were fed as follows: (1) Ad libitum at both temperatures, (2) those at 72° restricted to the intake of those at 90°, and (3) same as (2) with additional supplement of thiamine. Results showed that a loss of weight occurred with lowered food consumption which was not markedly improved in group (3) receiving additional thiamine. The ad libitum-fed rats at 90° consumed 10 gm. of food daily v. approximately 20 gm. consumed by those maintained at 72°.

A similar type of experiment with restricted and ad libitum feeding was carried out in which the daily thiamine intake was limited to 5, 10, and 30  $\mu$ g. per day. Results were comparable in that the amount of food consumed was a greater factor in weight change than the amount of thiamine in the diet. However, with restricted food consumption, best growth occurred at the highest levels of thiamine, although better growth resulted under tropical conditions than under temperate ones.

A third experiment used thiamine doses of 0, 30, and 300  $\mu$ g. per day. Even with the highest level of thiamine intake, the rats in a tropical environment consumed 30 to 50 percent less food than their paired mates at 72°. On a thiamine deficient diet, the incidence of polyneuritis was greater and appeared earlier in the rats maintained at 72° than those held at 90°. There was no significant difference among tropical and temperate groups in concentration of riboflavin, pantothenic acid, or nicotinic acid.

**Surveys of the nutrition of populations.—V, The vitamin C nutrition of a rural population in middle Tennessee,** J. B. YOUNG, E. W. PATTON, W. R. SUTTON, R. KERN, and R. STEINKAMP (*Amer. Jour. Hyg.*, 42 (1945), No. 3, pp. 254-261).—This report deals with the vitamin C nutrition of a population whose nutritional status with respect to other factors has been previously described (E. S. R., 93, p. 652). Records of the dietary intake revealed a vitamin C deficiency in a large proportion of the population. Medical history and physical examination of the subjects studied disclosed no cases of scurvy and infrequent clinical evidence of significant deficiencies; X-ray examinations revealed only one instance of bone changes indicative of mild scurvy. No subject tested failed to show some vitamin C in the blood, and only 10 subjects had a concentration less than 0.1 mg. per 100 cc. Assuming that concentrations below 0.3 mg. represent a subnormal state, 92 subjects (adult), representing 8.6 percent of those examined, were deficient.

**Effect of home cooking practices on the ascorbic acid content of frozen and canned lima beans,** H. I. WADSWORTH and E. B. WILCOX. (Utah Expt. Sta.), (*Jour. Amer. Dietet. Assoc.*, 21 (1945), No. 5, pp. 289-290).—Assays were made on the Henderson Bush variety of lima beans harvested green. The beans were shelled, washed, blanched 2½ min. in steam, cooled, then either quick frozen or canned in No. 2 cans. The fresh and blanched samples were assayed immediately, while the canned samples were stored at 72° F. for 4-9 weeks and the frozen beans kept at 0° for 14-18 weeks before testing. The fresh beans contained an average of 27.9 mg. ascorbic acid per 100 gm. fresh weight. The steaming-blanching caused a loss of ascorbic acid averaging 28 percent (19.9 mg./100 gm. beans).

The canned beans were assayed after various treatments—(1) after removal from can, (2) boiled 10 min. in a covered saucepan, and (3) held 24 hr. at 5° C. after the boiling and then reheated. Slightly less than 50 percent of the amount retained after blanching remained in the drained canned beans. Further losses occurred during the heating and holding procedures. Ascorbic

acid values of the drained beans were as follows: (1) 9.0, (2) 8.3, and (3) 6.0 mg./100 gm.

The frozen beans were assayed at the following stages: (1) Unthawed, (2) boiled 17 min. in tap water, (3) after holding the boiled beans 20 min. at 65°, (4) after holding 45 min. at 65°, (5) after holding the boiled beans 24 hr. at 5° then reheating to the boiling point, (6) boiled 17 min. in distilled water, and (7) boiled 15 min. in tap water containing  $\text{NaHCO}_3$  (0.22 gm. in 75 cc. water). Ascorbic acid retention in the boiled frozen beans was somewhat greater than in the canned beans. Losses on holding were high. The ascorbic acid content, per 100 gm. of beans, in milligrams, were as follows: (1) 19.1, (2) 9.9, (3) 7.6, (4) 5.0, (5) 4.0, (6) 10.6, and (7) 11.2.

The results showed that sodium bicarbonate in the concentration used did not affect the retention of ascorbic acid in lima beans.

**Ascorbic acid content of the mango in relation to variety, H. E. MUNSELL** (*Food Res.*, 11 (1946), No. 2, pp. 95-98).—The majority of the fruits studied were selected with regard to uniform conditions of quality and ripeness at either the Federal or the University Experiment Station in Puerto Rico. Some samples were also obtained from St. Thomas, V. I., and from local vendors. Twenty-eight varieties were assayed, two samples of each variety being examined in most cases. Ascorbic acid was determined by an indophenol dye titration method.

Ascorbic acid values were found to range from 6.87 to 130.81 mg. per 100 gm. edible portion. Results obtained on two fruits of the same variety were similar irrespective of the locality in which they were obtained. Fruits of the Cambodiana variety (of equal maturity), whether from Mayaguez or Rio Piedras, assayed within the range of 30.59 to 37.50 mg. Mangoes of the Martinique variety from Mayaguez and from St. Thomas assayed 51.09 to 59.34 mg.

The common variety (mango pasote) averaged about 10 mg. per 100 gm. Three of the varieties studied: Climoise No. 3304, Governor Seedling No. 2, and Mango de hilo averaged over 120 mg. per 100 gm.

**Tolerance curve of vitamin, C. M. ANDERSON.** (Ohio State Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 60 (1945), No. 1, pp. 12-14, illus. 1).—Twelve young college women, in a fasting state, were given 250, 500, 750 and 1,000 mg. of ascorbic acid orally. Lunch was limited to vitamin C-free foods. Blood samples were withdrawn at hourly intervals from immediately before to 6 to 10 hr. after the test dose. Vitamin C was assayed on the blood plasma by the Farmer-Abt micro-method (E. S. R., 75, p. 588).

Results showed that the maximum increase in ascorbic acid concentration occurred 1 to 4 hr. after a test dose was given. After the 250 mg. test dose, plasma levels reached their highest point (approximately 0.32 mg. increase) after 2 hr. With the other levels of dosage, peaks occurred in about 3 hr. (increases of approximately 0.62 to 0.67 mg. per 100 cc. plasma), with all three curves falling within a narrow range of less than 0.1 mg. variation over the 10-hr. period.

**Effect of feeding glucoascorbic acid to white rats, chicks, and guinea pigs, S. BANERJEE and C. A. ELEVEHJEM.** (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 60 (1945), No. 1, pp. 4-7, illus. 1).—Cotton rats and mice failed to grow, developed severe diarrhea, and showed hemorrhages in various parts of the body when fed a synthetic diet containing 10 percent glucoascorbic acid. Similar but less severe symptoms appeared where ascorbic acid alone was used. Autopsy revealed no hemorrhages in any part of the body. Animals fed 2 percent liver powder in addition to either 10 per-

cent glucoascorbic acid or ascorbic acid showed moderate diarrhea but normal growth. Glucoascorbic acid at levels of 5 and 1 percent also produced diarrhea.

Chicks showed no adverse effect of 10 percent glucoascorbic acid when it was added to a synthetic ration containing 2 percent solubilized liver. Severe loss of weight and diarrhea occurred in guinea pigs when 10 percent glucoascorbic acid was added to a natural diet. The addition of 10 percent ascorbic acid did not alleviate the symptoms, which were prevented by the addition of 6 percent 1 : 20 liver powder.

The authors suggest that the unfavorable effect of glucoascorbic acid in the diet of rats and guinea pigs may not be due solely to avitaminosis C action, but to a "lack of some factor other than vitamin C which is normally supplied by the intestinal flora and which is present in the liver 1 : 20 powder."

**Secretion of vitamin D in milks of women fed fish liver oil**, L. J. POLSKIN, B. KRAMER, and A. E. SOBEL (*Jour. Nutr.*, 30 (1945), No. 6, pp. 451-466).—Mothers appearing at the prenatal clinic were divided into groups and received varying amounts of vitamin D during pregnancy. A high protein, low fat diet was prescribed at the time but could not be checked.

Of those mothers receiving no preformed vitamin D during pregnancy, the majority showed less than 10 International Units per quart in their milk.

The average vitamin D content per quart of milk in the supplemented groups was as follows: (1) 10 I. U. for those receiving less than 100,000 I. U. of supplement; (2) 53 I. U. for those receiving between 128,000 to 224,000 I. U. of supplement; (3) 62 I. U. for those receiving between 256,000 to 320,000 I. U. of supplement; and (4) 53 I. U. for those receiving between 416,000 to 480,000 I. U. of supplement.

When the supplements were given during labor or for about 10 days thereafter, values of 91 to 583 I. U. were found.

The authors conclude "that for the purpose of fortifying human milk with vitamin D for infant use, supplementation of the mother with fish liver oil during pregnancy is not a practical method. . . . Vitamin D must be taken just prior to or during lactation in order to enrich the milk with the factor appreciably.

"The minimal dose of vitamin D which, when added as a supplement to the mother's basal diet, will yield a satisfactory increase of vitamin D in her milk has not been determined."

References cited number 61.

**Experimental rickets in the hamster**, J. H. JONES (*Jour. Nutr.*, 30 (1945), No. 2, pp. 143-146).—Experiments showed that on a diet containing approximately 0.4 percent calcium and 0.02 percent phosphorus, with no added vitamin D, hamsters developed all of the symptoms characteristic of experimental rickets observed in the rat on similar diets. On a diet containing optimal amounts of calcium and phosphorus and no vitamin D, calcification was as rapid as on the same diet containing added vitamin D. To produce typical rickets in the hamster, the diet must be low in phosphorus as well as deficient in vitamin D.

**The relationship between vitamin M and the Lactobacillus casei factor**, P. L. DAY, V. MIMS, and J. R. TOTTER. (Univ. Ark.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 45-52, illus. 4).—Young rhesus monkeys were fed a vitamin M-deficient diet until characteristic symptoms appeared—anemic, leucopenia, loss of appetite, mild necrosis of the gums, and severe diarrhea. Highly purified *L. casei* factor was given intramuscularly, and produced immediate and marked improvement in the deficient animals. Erythrocyte counts, hemo-

globin levels, and white blood cells increased to normal or near normal levels. Reticulocytes increased sharply within 4-7 days after injection. The authors conclude that these experiments furnish "convincing evidence of the effectiveness of highly purified *L. casei* factor in vitamin M-deficient monkeys."

Further tests indicated that *L. casei* factor was relatively inert in stimulating the growth of *Streptococcus faecalis* until treated with an enzyme preparation from rat liver. After enzyme treatment, the activity for *S. faecalis* was comparable to that of a standard B<sub>12</sub> preparation. The authors assume that for nutrition of the higher forms of life (rat, chick, and monkey) the *L. casei* factor, vitamin B<sub>12</sub>, and vitamin B<sub>12</sub> conjugate are interchangeable.

**Vitamin P content of vegetables as influenced by chemical treatment, T. Y. Lo and S. M. CHEN** (*Food Res.*, 11 (1946), No. 2, pp. 159-162).—Chinese red pepper (*Capsicum annuum*), peas (*Pisum sativum* L.), and Chinese lettuce were studied in experiments designed to test the influence of specific chemical substances upon the formation of vitamin P in vegetables. Field experiments were carried out using sulfates and nitrates of Ni, Al, Zn, Mg, Cu, and Fe, uranyl acetate, and molybdenum oxide, and a "complete fertilizer" singly or in combination. Vitamin P was estimated according to the method of Lorenz and Arnold (*E. S. R.*, 87, p. 482).

Values in milligrams per gram fresh basis ranged as follows: Peppers, 1.360-1.763; pea shoots, 1.335-1.671; green peas, 2.250-2.922; Chinese lettuce leaves, 3.531-5.570; and Chinese lettuce stems, 0.352-0.565.

Tabulated results indicate that compounds of Ni, Zn, and Mo seem to promote vitamin P formation in plant metabolism.

## TEXTILES AND CLOTHING

**A comparison of some Alabama manufactured chambrays, seersuckers, and denims with similar fabrics in ready-to-wear, G. M. SMITH and H. M. THOMPSON** (*Ala. Univ., School Home Econ. Bul.* 10 (1946), pp. 16+).—The physical characteristics of 16 Alabama-manufactured chambrays, seersuckers, and denims were compared with 12 ready-made dresses, slack suits, and overalls obtained in retail stores or mail-order catalogs. Determinations were made on count in yarns per inch, twist, raveled strip breaking strength, elongation (warp and filling) weight per square yard, sizing, staple length of fiber, abrasion resistance, shrinkage, and colorfastness to light and laundering. The procedures found in A. S. T. M. standards were followed for tests except for staple length of fiber, shrinkage, desizing, and abrasion resistance.

The Alabama-manufactured chambrays and seersuckers were superior in breaking strength and resistance to abrasion, faded less when exposed to light or when laundered, although they shrank more and had a higher percentage of sizing than the ready-to-wear studied. As a whole, there was little difference between the Alabama denim fabrics and ready-to-wear overalls, although the former showed greater resistance to abrasion and faded less when exposed to light.

**Smart styles from Alabama cottons, H. M. THOMPSON and G. SMITH** (*Ala. Univ., Ext. News Bul.*, 3 (1946), No. 10, pp. 16, about 20 illus.).—This leaflet presents information based on a study which was conducted in the textile, clothing, and related art department of the school of home economics. Special emphasis is made on the original clothing designs worked out by the students for utilization of cotton fabrics.

**Cotton and rayon fabrics used for glass curtains** (*Ohio Sta. Bul.* 659 (1945), pp. 170-171).—Previously noted (*E. S. R.*, 90, p. 573).

"In general, cotton glass curtain fabrics gave evidence of being more durable and serviceable than rayon fabrics of similar construction because of their greater dry strength, gain in strength when wet, and smaller loss in strength after laundering. There was some relation between price and breaking strength, especially in the low and medium priced ranges. However, the most expensive fabrics were sometimes made of such fine yarns that they were weaker than lower priced fabrics. Effects of exposure to light varied with individual fabrics, loss in strength being appreciable in fabrics exposed at north windows. Except for acetate rayon, all fabrics lost more strength when stretched than when ironed. Of the rayons which were ironed, viscose voile lost the least strength and cellulose acetate ninon the most. When stretched, cellulose acetate lost less strength than viscose or cuprammonium rayon. Upon exposure to light the three fabrics which changed most in hue were cellulose acetate rayons. The colorfastness to light of cotton marquisesettes and fllet and colorfastness to laundering of cotton marquisesettes had some relation to price. There was appreciable shrinkage in most fabrics, especially in marquissette and bobbinet. Price was not closely related to shrinkage."

**Effect of fiber content and care on resiliency, thickness, and thermal conductivity of blankets.** P. A. GILMORE and K. P. HESS. (*Kans. Expt. Sta.*). (*Rayon Textile Mo.*, 27 (1946), No. 5, pp. 78-82, *illus.* 3).—The breaking strength, weave, thread count, weight per square yard, and percentage of finish of 13 blankets of varying fiber contents were determined by standard A. S. T. M. methods. Resiliency and thickness tests were made by means of a Saxl Compressometer. Wool blankets were found to be more resilient than blends, and blends containing wool were, in most cases, more resilient than those containing no wool.

The Cenco Fitch conductivity apparatus was used in determining the thermal conductivity of the blankets. Blends of cotton and rayon and of rayon, wool, and cotton, and an all-cotton blanket were found warmer than all wool ones. However, variation in protective value was comparatively small in the blankets of the same thickness.

With one exception, laundering and dry cleaning increased the protective value of all blankets containing wool and decreased with those containing cotton. Five launderings resulted in warp shrinkage of 6 to 16 percent, with all-wool blankets having the lowest percentage. Five dry cleanings caused the fabrics to shrink in the warp from one-tenth to five-tenths as much as did the five launderings.

**Devices for producing artificial rainfall for tests of water-repellent and waterproof materials.** M. I. LANDSBERG and F. J. MOODY (*Textile Res. Jour.*, 16 (1946), No. 5, pp. 211-218, *illus.* 12).—This article is one of a series of technical papers emanating from the laboratories participating in the Quartermaster Corps research program dealing with the principal phases of the research, development, and production problems of water-repellency. Simulating rainfall intensities, drop sizes, and drop velocities similar to those found in natural rainfall were produced by three nozzles furnishing approximately 0.1, 1, and 3 in. of rainfall per hour. Measurements have indicated that the sizes of the drops produced by the three nozzles agree with the sizes of the drops found in natural rains of similar intensities. These measurements are described, and variables were studied in the development of the work, including water pressure, nozzle height, design, and orientation with respect to the horizontal.

**Selection of sewing thread** (*Ohio Sta. Bul. 659 (1945), p. 170*).—"Heavy duty thread was outstanding in single strand strength, and it was the strongest when made up into seams, nylon thread being next highest in seam strength. Elongation at break was much greater for nylon thread than for any cotton thread, and 6-cord cotton thread had slightly higher elongation than 3-cord unmercerized cotton thread. In general, unmercerized cotton thread had the best balance of twist and caused least difficulty in hand sewing, while mercerized cotton thread and nylon thread were most poorly balanced and caused the greatest difficulty in hand sewing. Thread characteristics which varied considerably among different brands of the same type of thread were price, balance of twist, seam strength, ease of use in hand sewing, and color-fastness to laundering. The only consistent relationship of price to quality of a given type of thread applied to 6-cord thread, the lowest priced brand being the weakest and having the lowest elongation. Some useful information was supplied on labels of most of the thread tested."

See also a previous note (E. S. R., 91, p. 367).

## HOME MANAGEMENT AND EQUIPMENT

**Time expenditures on homemaking activities in 183 Vermont farm homes, VI. MUSE** (*Vermont Sta. Bul. 530 (1946), pp. 72, illus. 9*).—This bulletin reports data obtained from 183 housewives of Chittenden County, Vt., during a period of 3 weeks in 1943. Through eligibility requirements set up for the families, a sufficiently homogeneous sample was provided for the purpose of study. The findings concerned with the allocation of the housewife's time showed that homemaking activities averaged 64½ hr. during 1 week, amounting to 38 percent of their total time and 59 percent of their waking hours. Food preparation, house cleaning (including care and upkeep), and dishwashing took 28, 21, and 12 percent of housewives' time. The homemaker did all the child care in 46 of the homes reporting and part of it in 32 of them, spending an average of 11½ hr.

Persons other than the housewife gave an average of 17¼ hr. to homemaking, with hired workers in 26 cases averaging 25½ hr. for the week. In 9 percent of the homes, women and girls of the family, other than the housewife, spent a total of 35 hr. or more during the week on homemaking activities—an additional 29 percent of the cases spent between 10 and 34¼ hr. Food preparation took 25 percent of all persons' time contributing to homemaking, dishwashing 15, housecleaning, care, and upkeep 22, care of household members 10, care of clothing and household linens 9, food preservation 6, and marketing and household business 3 percent.

Relationships were found between the amount of time spent on homemaking activities and the number of persons living in the household, as well as to the age of these persons. The time spent on these activities averaged 50 hr. for the week for two-person-households and rose to 119¼ for nine-person ones. Relationships between time expenditures and accomplishment of job as well as between time expenditures and efficiency, were also factors contributing to the allocation of the homemakers' time.

**Some effects of the height of ironing surface on the worker, E. KNOWLES** (*[New York] Cornell Sta. Bul. 833 (1946), pp. 57, illus. 35*).—Certain physiological responses of a homemaker while ironing have been previously noted (E. S. R., 95, p. 285); however, this full report gives technical detailed analyses of the results of the controlled laboratory tests given to the 23 subjects. In the study of selection of desirable working heights the use of a

leveling platform was employed to measure stature; the wooden anthropometer for height of shoulder, bust, hip, and knee; a protractor head for slope of shoulder; spreading calipers for breadth or arc of the body; and tapes for certain measurements.

In addition to analyses of posture from motion films, mechanical platforms and attachments recorded the force exerted on the ironing board, postural balance, heart rate, and time. In this portion of the study, the subjects were found to assume a less favorable posture, pressed harder on the ironing board, and moved about too often to maintain posture at a height that was selected by them as more desirable. It was not until the subjects were given the opportunity to try different heights for ironing that they finally selected a board at a height at which their responses were most favorable.

"This study offers evidence that a desirable height cannot be established by rule-of-thumb method, nor can the body height be the criterion for the selection. . . . From the experience of the writer with this and previous studies, there seems, as yet, no satisfactory way for prescribing desirable working heights for an individual except through individual experimentation, which can be of a simple nature. Many factors influence the selection."

## REPORTS AND PROCEEDINGS

**Fifty-eighth Annual Report of the [Michigan Station], 1945, V. R. GARDNER** (*Michigan Sta. Rpt. 1945, pp. 215-241*).—This consists mainly of lists of the publications of the year and of the active projects as of May 1, 1945. Results are also noted of studies on the mow drying of hay, new oil-wax emulsions, sheep parasites, penicillin and phemerol for mastitis control, a disease-resistant strain of the Honey Rock cantaloup, chemical control of weeds, a wilt-resistant mint, role of vitamins for dairy calves, use of DDT, fertilizers for fish ponds, a field-size vacuum sweeper for harvesting clover seed, relation of bees to clover and alfalfa seed production, control of potato scab, farm land prices, farm efficiency, radish seed vitality, band distribution of fertilizers in sod-culture orchards, and use of disease-free stock to control cherry yellows.

**Farm science and practice. Sixty-third annual report of the Ohio Agricultural Experiment Station for the year ended June 30, 1944, E. SECREST** (*Ohio Sta. Bul. 659 (1945), pp. 197, illus. 52*).—In addition to results noted elsewhere in this issue, this report includes data on farm income and living, including suggestions for attaining maximum agricultural production in Ohio in 1945, postwar problems, prepaid medical care for low-income farm families, country transportation of milk, factors affecting the milk supply in Akron, Canton, Dayton, and Portsmouth, and relationships between co-operative organizations; soil management, including the use of alfalfa, soybeans, and sweet-clover in rotations, and of alfalfa in soil erosion control, crown vetch as a bank cover, plowing under heavy applications of fertilizer and chemical nitrogen to increase corn yields, potash as a limiting factor in crop production, livestock v. a grain rotation, effect of rotation on soil structure and crop yield and of soil compaction on legume seedlings, mobility of added potash, injury by wheat straw to meadow seedlings, and a limestone evaluation chart; pasture and hay, including improved varieties and strains of alfalfa, bromegrass, Cumberland clover, hot-weather legumes for permanent pastures, pasture rotation, and white grub investigations; silage, including corn, sorgo, and alfalfa-cheat silage, density data, tests of the "silage carburetor," chemical and microbiological studies, effects of temperature and

chopping, palatability studies, and value of trench silos; grain, including corn studies as to hybrids and storage, oat and soybean varieties, defoliating soybeans to facilitate harvesting, wheat varieties and quality tests, and control of the European corn borer; livestock and poultry, including the value of corncocks for fattening steers, cross-breeding beef cattle, effect of calcium and phosphorus levels on reproduction in dairy cattle, levels of carotene and vitamin A in the plasma of dairy cows, vitamin D as an aid in controlling milk fever, value of amino acids in prolonging the storage of spermatozoa, effect of skim milk and potassium iodide on semen quality, legume silage as a roughage for sheep, protein sources for pigs on pasture, soybean oil meal for pigs on dry lot, cross-breeding hogs, crystal violet vaccine for hog cholera preventive, need of pantothenic acid by swine, poultry feed requirements, free choice v. limited feeding of whole grain to pullets, value of pasurage for chickens and pullets, need and sources of calcium and vitamin D by layers, a device for testing the breaking strength of eggshells, debeaking to control cannibalism, and dried fermentation solubles v. milk products in chick rations; fruits, including apple varieties and production costs, soil factors limiting grape yields in Ohio, cultural studies with peaches and raspberries, pear breeding for blight resistance, spraying for apple scab and cherry leaf spot, new fungicides for apple bitter rot, studies of the oriental fruit moth, Comstock's mealybug as a pest of apples, the peach tree borer, and lespedeza as a soil cover; vegetables, including studies of the susceptibility of cucumbers to bacterial wilt, quick freezing to control the bean weevil, susceptibility of bean varieties to various insects and onion varieties to thrips, potato varieties for yield and leafhopper resistance, new materials for potato sprays, hormone tests with potatoes, barley as a potato cover crop, sunflowers and rye as supplementary crops, resistant varieties of tomatoes to wilt and anthracnose, control of soil-borne diseases of glasshouse vegetables by nutrient solutions, new fungicides for vegetables, and the influence of a leaf character on adhesion of copper fungicides to vegetable leaves; foods, including vitamin potency of Ohio butter and evaporated milk, therapeutic value of milk from thyroidectomized goats, mineral content of tomatoes, conservation of vitamin C and calcium in tomatoes, collards, cabbage, and strawberries, fertility levels and carotene content of vegetables, and varieties of vegetables recommended for freezing; special crops, including the use of segmented sugar beet seed, loss of sugar beet seedlings due to *Aphanomyces cochlioides*, tobacco cultural tests, and production of belladonna; forestry, including timber production for war and postwar years, reforestation, recreational use, fire protection, timber marketing, preservative treatment of fence posts, blight-resistant chestnuts, and sawfly damage to forest plantings; turf and ornamentals, including control of buckhorn by Sinox, white grubs by arsenate of lead, aster wilt by breeding, and black spot of roses by organic fungicides, culture of greenhouse roses, early flowering of gardenias, propagation of chysanthemums and roses, effect of the photoperiod and temperature on the flowering of azaleas, and flower-bud differentiation in hydrangeas; agricultural engineering, including farm refrigeration, ventilation of ear corn and grain, forced ventilation of partially cured hay, and food dehydration; control of the Japanese beetle in Ohio; and meteorological observations for 1943.

**Oklahoma crops and soils, 1946** (*Oklahoma Sta. Bul. 295 (1946)*, pp. 111, illus. 10).—This is a report on current research as presented at the First Annual Oklahoma Crops and Soils Conference, and includes the following papers: Cooperative Studies at the Stillwater Outdoor Hydraulic Laboratory,

by V. J. Palmer (pp. 5-13) (U. S. D. A.); The Value and Interpretation of Chemical Tests for Available Plant Nutrients in Soil, by H. J. Harper (pp. 14-22); Summary of Chlorosis Experiments With Grapes at the Southern Great Plains Field Station, Woodward, Okla., by L. F. Locke (pp. 23-28) (U. S. D. A.), noted on p. 679; Wide Row Spacing of Small Grain As a Nurse Crop for Sweet Clover and Lespedeza, by H. J. Harper (pp. 29-30); New Developments and Interpretation of Conservation Surveys, by L. E. Derr (pp. 31-35) (U. S. D. A.); Competition Between Alfalfa and Pecan Trees for Available Moisture, by F. B. Cross (pp. 36-37); Fertilizer in Relation to Oklahoma Agriculture, by H. F. Murphy (pp. 38-44); Effect of Dates and Depth of Tillage on Wheat Yields, by W. M. Osborn (pp. 45-50) (U. S. D. A.); Moisture Conservation and Wheat Production, by H. A. Daniel (pp. 51-54) (coop. U. S. D. A.); Grass in Crop Rotations, by V. C. Hubbard (pp. 55-59) (U. S. D. A.); Progress in Corn Improvement (abs.), by J. S. Brooks (p. 60) (E. S. R., 95, p. 195); Progress in Sorghum Improvement, by J. B. Seiglinger (pp. 61-64) (U. S. D. A.); A Year-Round Pasture Program, by H. W. Staten (pp. 65-67); Results of Sagebrush Control Studies at Woodward, Okla., by D. A. Savage (pp. 68-70) (U. S. D. A.); Machinery for Brush Removal and Control, by M. B. Cox (pp. 71-74) (coop. U. S. D. A.); Poisons for Eradicating Brush—Progress Report, by H. M. Elwell (pp. 75-76) (U. S. D. A.); Chemicals for Eradicating Weeds—Progress Report, by W. C. Elder, (pp. 77-78); and Revegetation of Eroded Land, by H. M. Elwell (pp. 79-84), Establishing Bermuda Grass From Seed, by C. W. Sittel (pp. 85-90), Kobe and *Sericea* Lespedeza in East-Central Oklahoma, by W. C. McCollum, (pp. 91-95), Grass Seed Harvesting, Cleaning, and Processing: A Summary of Techniques Developed by the Soil Conservation Service, U. S. Department of Agriculture, by J. E. Smith, Jr. (pp. 96-99), noted on p. 723; A Preliminary Study of the Distribution of Roots of *Ulmus pumila* in a Sand Dune, by E. W. Johnson (pp. 100-103), The Status and Use of Shelterbelts in Western Oklahoma, by H. R. Wells (pp. 104-108), and Urgent Agronomic Problems, by W. M. Nixon (pp. 109-111) (all U. S. D. A.).

**Fifty-seventh Annual Report [of Tennessee Station], 1944, [C. A. MOORES ET AL.]** (Partly coop. U. S. D. A.). (*Tennessee Sta. Rpt. 1944, pp. 107, figs. 23*).—Progress results are reported in agronomy, including variety tests with soybeans, sorghum, cotton, oats, and barley, cultural studies with hemp, Sudan grass and millets alone and with soybeans as emergency hay crops, button clover, crimson clover, hairy vetch, and Austrian winter peas as winter annual legumes and as green manure, seeding dates for pasture, grazing oats, barley, wheat, and rye, nitrogen sources for wheat, fertilizer tests with cotton, and tests of cyanamid as a defoliant, corn hybrids, grass breeding, erosion control, and physical properties of cotton; agricultural engineering, including transplanting studies with tobacco, irrigation for tobacco, alfalfa, corn, lespedeza, potatoes, and truck crops, use of a new disk scarifier and a power hay distributor, and tests of hot-water seed treatments; animal husbandry, including comparisons of corn silage v. sorghum silage for fattening steers and barley v. corn for hog feeding, protein supplements for hogs on pasture, grazing and feeding tests with beef steers, breeding studies with beef cattle, ewes, and mules, once v. twice daily feeding for fattening cattle, finishing yearlings under war conditions, sorghum-corn silage v. chopped sweetpotatoes for fattening yearlings, feeding cattle in mineral-deficiency areas, fused tricalcium phosphate as a feed supplement and its effects on breeding, feeding systems for dry cows, and pastures for laying hens and growing chickens; chemistry, including studies of the decomposition of car-

bonates in soils, economic additions of liming materials, calcium silicate slag v. limestone, lime-potash relationships, potassium sulfate v. potassium metaphosphate, lime-phosphate studies, home dehydration and freezing of fruits and vegetables, composition and preparation of legume silage, preparation of fruit juice concentrates, sweetpotato dehydration, and protein and minerals in forage crops; economics and sociology, including agricultural adjustments, types of farming, and cotton marketing; forest and farm economic surveys; entomology, including studies of sweetpotato injury by the flea beetle *Systema clongata*, bean beetle control, and insecticidal properties of some coal-tar products; home economics, including the retention of ascorbic acid in foods and ascorbic acid metabolism; horticulture, including irrigation for strawberries and turnips, varieties of strawberries, raspberries, and blackberries, peas, tomatoes, cabbage, sweetpotatoes, sweet corn, and gladiolus, and spacing and mulching tests with garden sage; plant pathology, including bean diseases, wilt-resistant cotton, and leaf spot and wilt of tomatoes and watermelons; and at the branch stations variety and fertilizer tests with wheat, oats, and barley, seeding tests with oats and barley, varieties and rate of seeding with sorghums, rate of liming, eradication of bitterweed, pasture grazing crops, rotations, fertilizers, varieties and rates and dates for planting corn, tobacco irrigation and topping of tobacco, legume silages and grain for calves and steers, and fertilizers and irrigation needs for bush beans and tomatoes.

## MISCELLANEOUS

**Abbreviations of generic names.** C. E. SKINNER. (Univ. Minn.). (*Science*, 104 (1946), No. 2690, p. 62).—The author points out that "the practice of using abbreviations for generic names is admissible only in cases where it does not lead to confusion," and argues that since there are no official generic abbreviations, in the interests of scientific accuracy the full scientific name should be used at least once in an article in which generic abbreviations are used.

**A multiple light source microscope.** G. I. LAVIN (*Science*, 104 (1946), No. 2690, p. 61, illus. 1).—The apparatus described renders it possible to photomicrograph tissues, using visible, infrared, polarized, fluorescent, and 2,537 a. u. light, for purposes of comparison under the different wavelengths.

**Particle counts in the ultramicroscope.** E. H. M. BADGER (*Nature* [London], 157 (1946), No. 3989, p. 480).—A brief note on errors in counting.

**Polk County, Texas—a geographic survey.** E. M. SMELLEY (*Tex. Geog. Mag.*, 9 (1945), No. 1, pp. 15–21, illus. 3).—This survey includes brief reports on the geographic divisions, forestry industries, agriculture, oil industry, livestock production, and trade and transportation of the county.

**Canada's agricultural resources** (*Agr. Inst. Rev.* [Canada], 1 (1946), No. 5, pp. 277–295, about 40 illus.).—Papers are included as follows: The Place of Agriculture in the Canadian Economy, by W. M. Drummond (pp. 279–283, 321); The Agricultural Soil Resources of Canada, by A. Leahey (pp. 285–289); Water for Irrigation, by B. Russell (pp. 291–294); Cultivated Hay and Pasture Crops and Natural Grazing Lands, by T. M. Stevenson and S. E. Clarke (pp. 295–301); Cereal Grains, by L. H. Newman (pp. 303–304, 307–309); Fruits and Vegetables, by M. B. Davis (pp. 311–313, 315); Meat and Wool, by J. G. Taggart and F. M. Schrader (pp. 317–321); Dairy Cattle, by A. R. Ness (pp. 323–325, 327); Poultry and Egg Production, by J. R. Cavers (pp. 329–333); Special Crops, by J. Coke (pp. 335–341); The Farm Woodlot, by G. A. Mulloy (pp. 343–345); Fur Farming, by C. K. Gunn

(pp. 347-349); Farm Mechanization and Electrification, by E. A. Hardy (pp. 351-353); Marketing and Processing Facilities, by W. C. Hopper (pp. 355-361); Industrial Use of Agricultural Products, by W. H. Cook (pp. 363-368); Canada's Contribution to World Food Requirements, by F. Shefrin (pp. 369-371, 373-375); The Farmer, by H. S. Fry (pp. 377-379, 381-382); Agricultural Science and Education, by L. E. Kirk (pp. 383-387); and The Future of Canadian Agriculture, by E. S. Archibald (pp. 389-391, 393, 395).

**Colorado Farm Bulletin [May-June 1946]** (*Colo. Farm Bul. [Colorado Sta.]*, 8 (1946), No. 3, pp. 15, illus. 11).—In addition to several articles noted elsewhere in this issue, this number contains Gadgets Load Hay the Easy Way (pp. 4-5), which describes the use of an 18-ft. "needle" made from a pump rod, two chains, and a low-platform hayrack; and Feed the Right Amino Acids, by A. R. Patton (pp. 13-14).

This is the final issue of this publication, which has been superseded by the *Colorado A & M News*.

**Mississippi Farm Research [February 1946]** (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 2, pp. 8, illus. 2).—In addition to articles noted elsewhere in this issue and meteorological notes for January 1946, this number contains Soil Survey Program for Mississippi, by H. B. Vanderford (pp. 1, 2, 4); Cotton Production Costs in Northeast Mississippi, by W. J. Edens (pp. 3, 4), also to be issued as a station bulletin; Suggestions for Control of Parasites in Horses, by J. W. Scales (pp. 1, 6); and High Vitamin A Content in Creamery Butter Kept in Winter by Supplemental Grazing, by F. H. Herzer (p. 8).

**Research and Farming [April 1946]** (*Res. and Farming [North Carolina Sta.]*, 4 (1946), Prog. Rpt. 3, pp. 12, illus. 11).—In addition to several articles noted elsewhere in this issue, this number contains The Trend in N. C. Crops, by R. E. L. Greene (pp. 3, 9), showing the yields per acre, acreage, and production of the major crops in North Carolina, 1866-1945; and Summer Rains Take the Soil, by T. L. Copley and L. A. Forrest (p. 12) (coop. U. S. D. A.).

**Bimonthly Bulletin [May-June 1946]** (*North Dakota Sta. Bimo. Bul.*, 8 (1946), No. 5, pp. 31, illus. 6).—In addition to articles noted elsewhere in this issue and several reviews and abstracts, this number contains Diseases of the Respiratory System of Chickens, by D. F. Eveleth and F. M. Bolin (pp. 3-6); How to Use the Veterinary Laboratory (pp. 7-8) and Mastitis or Garget (pp. 9-10), both by D. F. Eveleth; Brand Inspection of Livestock for North Dakota, by L. E. Arndt (pp. 13-18); The Land Market in North Dakota, 1941-1945, by J. W. Porter and R. Engelking (pp. 19-22) (coop. U. S. D. A.); and North Dakota Farm Prices, by P. V. Hemphill (pp. 23-25).

**Abstract of new publications and list of publications available** (*Oklahoma Sta., What's New in Okla. Farm Res. No. 10* (1945), pp. 16).—This consists mainly of Bulletins 284-290, Circular 119, Technical Bulletins 21 and 22, and Mimeographed Publications 136, 139, and 145, all of which have been previously noted; and also of the following: Mimeographed Publications 135, Fattening Lambs on Wheat Pasture, by H. M. Briggs (pp. 2); 137, Swine Improvement Through Inbreeding and Outcrossing, by O. W. Willham (pp. 3); 138, Protein Supplements for Fattening Swine, by C. P. Thompson and J. C. Hillier (pp. 3); 140, Rural Farm Housing Characteristics in Oklahoma, by R. T. McMillan (pp. 9); 141, Small Grain Results, 1945: Wheat, Oats, Barley, Flax (mistitled "rye" for "flax"), by C. B. Cross (pp. 11); 142, Grazing Trials: Winter Small Grains and Ryegrass, by H. W. Staten (pp. 13); 143, Forage Production of Winter Small Grain Varieties and Annual

Rye Grass, and Effect of Clipping Upon Grain Yields, by H. W. Staten and E. H. Muncrief (pp. 7); 144, Elm Diseases in Oklahoma, by K. S. Chester (pp. 3); 146, The Oklahoma Vegetable Research Station at Bixby—Progress Report, 1945, by H. B. Cordner and F. A. Romshe (pp. 10); 147, DDT—A New Insecticide, by F. A. Fenton et al. (pp. 8); 148, Instructions for Using DDT as a Barn and Cattle Spray, by F. A. Fenton (pp. 2); 149, Supplements for Fattening Two-Year-Old Steers on Grass, by A. E. Darlow et al. (pp. 5); 150, Oklahoma Farm Production Prospects for 1946 (coop. U. S. D. A.); 151, Oklahoma Farm Wheat Improvement Program, 1944–45, by R. M. Oswalt (pp. 5); 152, DDT as a House, Restaurant, or Dairy Spray, by F. A. Fenton (pp. 33); 153, The Southwestern Corn Borer, by R. R. Walton (pp. 4); and 154, Brush Mowing Machines, by M. B. Cox (pp. 5). A list of available station and extension publications is appended.

**Farm and Home Science [June 1946]** (*Farm and Home Sci. [Utah Sta.]*, 7 (1946), No. 2, pp. 20, about 20 illus.).—In addition to several articles noted elsewhere, this number contains Economical Turkey Production in Utah, by B. Alder (pp. 1, 17), which stresses the importance of using economical feeds; *Lygus* Control on Sugar Beets Grown for Seed, by G. F. Knowlton and W. E. Peay (pp. 11–12) (coop. U. S. D. A.), pointing out that dusting with 10 percent DDT increases seed production; and Yield of Onion Seed Increased by Thrips Control, by W. E. Peay and C. J. Sorenson (p. 12).

**Bibliografía puertorriqueña, 1493–1930**, A. S. PEDREIRA (*Puerto Rico Univ. Monog., Estud. Hispánicos, Ser. A, No. 1* (1932), pp. 707+).—This comprehensive bibliography of Puerto Rican literature includes subsections on agriculture (pp. 148–199), silviculture (pp. 199–202), and zootechny (pp. 202–210).

**Jewish agriculture in Palestine**, L. SAMUEL (*Jerusalem: Jewish Agency for Palestine, Econ. Res. Inst., 1946*, pp. 143+, illus. 6).—This survey contains much statistical data. The first section deals with the markets for the main products other than citrus and the second with suggestions for a sound agricultural policy.

**[Recent advances in science]** (*Sci. Prog. [London]*, 34 (1946), No. 136, pp. 778–786, 795–805).—The following are included: Biochemistry, by W. O. Kermack (pp. 778–786); Plant Physiology, by W. Stiles (pp. 795–800); and Entomology, by A. D. Lees (pp. 800–805).

**Confidence limits for biological assays**, C. I. BLISS. (Conn. [New Haven] *Expt. Sta. et al. (Biometrics Bul., 1* (1945), No. 5, pp. 57–65, illus. 1).—"A large-sample approximation may be involved when fiducial or confidence limits are computed from the standard errors of the terms used in biological assays. In many cases a correct answer requires the exact limits, which are not difficult to compute when their equations are reduced to a uniform symbolism. For experiments based upon a graded response the exact limits cover the log-dose for both a given and an observed response and for two-dose design and the confounded two-dose design. Equivalent limits based upon an all-or-none or quantal response include these for a required effect, such as the LD50 and for the log-ratio of potencies." There are 24 references.

**The shadow-casting technique in electron microscopy**, T. F. ANDERSON (*Jour. Bact., 51* (1946), No. 4, p. 563).—An abstract.

**One man—Edward Asbury O'Neal III of Alabama**, P. O. DAVIS (*Auburn: Ala. Polytech. Inst., [1946]*, pp. 123, illus. 2).—This is an appreciative account by the director of the Alabama State Extension Service.

## NOTES

**Missouri University and Station.**—The death on November 12 is noted of Dr. F. B. Mumford following an automobile accident in October in which Mrs. Mumford was also killed. A detailed account of his life and service appeared in the *Record* at the time of his retirement as dean and director in 1938 (E. S. R., 79, p. 145). Since that time he had continued his interest in agricultural education and research, bringing out a series of station circulars on the postwar experiment station and a 300-page history of the Missouri College of Agriculture. He was also active in the Association of Land-Grant Colleges and Universities, serving as a member of the executive committee until 1941 and as president at the annual convention of that year.

**Nebraska University and Station.**—The resignations are noted of Dr. H. D. Tate, professor and chairman of the department of entomology, to engage in commercial work, and Arnold Gadeken, assistant in rural economics, to go into agricultural extension. Recent appointments include Drs. Ephraim Hixson and Carl Olson, Jr., as professors of entomology and animal pathology, respectively, and chairmen of their departments; Dr. Ian W. Tervet as associate professor of plant pathology; Ralph Benton and I. L. Williams, Darrell D. Deane, and Lester F. Larsen as assistant professors of poultry husbandry, dairy husbandry, and agricultural engineering, respectively; Dr. Max L. Schuster as instructor in plant pathology; Gerald E. Abbenhaus and Arden Sherf as assistants in rural economics and plant pathology, respectively; and James C. Adams as superintendent of the North Platte Substation.

**New Hampshire University.**—Laurence A. Bevan has been appointed associate director of extension.

**Rutgers University.**—Edwin V. Bearer, associate professor of agricultural education since 1920, was killed in an automobile accident while traveling to address a group of high school students. He was 60 years of age.

**North Carolina College and Station.**—C. E. Van Deman, in charge of apple research at North Wilkesboro since 1937, has resigned to engage in commercial work. Mary E. Thomas, extension specialist in foods and nutrition since 1926, retired September 30. Eugene A. Wilkenning has been appointed instructor in rural sociology.

**North Dakota College and Station.**—Clifford C. Volkerding has been appointed associate soil scientist and assistant dean of agriculture.

**Ohio Station and State University.**—Dr. Carlos G. Williams, associated with the station since 1903, died October 4 at the age of 83 years. A native of Ohio, he served as station agronomist from 1903 to 1921, as director from 1921 until his retirement in 1937, and subsequently as consulting agronomist. He was president of the American Society of Agronomy in 1926 and vice president of Section O of the American Association for the Advancement of Science in 1931.

Dr. Joseph H. Gourley, chairman of the department of horticulture of the university and chief of horticulture in the station, died October 27 aged 63 years. A native of Pennsylvania, he received the B. S. degree from the University in 1908, the M. S. degree in 1915 from the University of Chicago, and

the Ph. D. degree in 1931. Beginning as assistant horticulturist in the station in 1908 he became assistant professor of horticulture in the university in 1910, and professor of horticulture and horticulturist in the New Hampshire College and Station in 1912 and the West Virginia University and Station in 1920, returning to Ohio in 1921. He served as president of the American Society of Horticultural Science in 1923 and subsequently as vice president of Section O in the American Association for the Advancement of Science.

**Oklahoma College and Station.**—Dr. R. C. Jaap, professor of poultry husbandry and poultry husbandman, has accepted a similar position in the Ohio State University. T. L. Runnels, who has been on naval leave from the West Virginia University and Station, has been appointed associate professor of poultry husbandry and Harry L. Hathaway assistant professor and assistant in that subject.

**Texas College.**—A department of range and forest management has been established with Vernon A. Young, professor of range management in the University of Idaho, as head and with Omer E. Sperry in charge of range plants and plant and range ecology and Robert R. Rhodes in charge of forestry work. D. H. Reid has been succeeded as head professor of poultry husbandry by Dr. J. H. Quisenberry, who has been serving as associate professor and poultry husbandman in the Hawaii University and Station.

**Washington College.**—Dean E. C. Johnson has been granted a year's leave of absence to go to Colombia as an agricultural advisor to the National Director of Agriculture at Bogota.

**Wisconsin University and Station.**—Recent grants for research include one of \$108,350 to aid a study of factors affecting the production and action of antibiotics on animal and plant diseases and one of \$30,000 for an industrial fellowship to study the nature and production of antibiotics; \$6,500 to assist in work on the subfractionation of globulins of horse serum and seasonal variations and other phases of the antigen-antibody relationship; \$2,000 for an industrial fellowship to study the nutritional requirements of micro-organisms; and two grants of \$850 each by the Holstein-Friesian and Guernsey breed associations for continuing the studies of the genetic factors in the blood of cattle.

Dr. J. J. Porter, instructor in veterinary science, was killed recently in an automobile accident while returning to his home after addressing a meeting of the State Veterinary Medical Association.

Dr. Conrad E. Elvehjem, professor and chairman of the department of biochemistry, has been appointed dean of the Graduate School.

**Office of Experiment Stations.**—Dr. Edward R. McGovran, entomologist in the division of control investigations of the U. S. D. A. Bureau of Entomology and Plant Quarantine, has been appointed experiment station administrator (entomology), vice Dr. Floyd Andre, whose appointment as assistant director of the Wisconsin Station and professor of entomology has been previously noted.

**U. S. Department of Agriculture.**—Harris P. Gould, associated with the horticultural work of the Bureau of Plant Industry, Soils, and Agricultural Engineering since its establishment in 1901 until his retirement in 1941 and from 1939 chief of its division of fruit and vegetable crops and diseases, died October 17 at the age of 75 years. A native of Maine, he had received the B. S. degree from the University of Maine and the M. S. A. degree from Cornell University. Prior to his coming to the Department he had served as assistant horticulturist in the Maine and Cornell Stations, as nursery and orchard inspector in New York, and as assistant entomologist and horticul-

turist in the Maryland College and Station. He was widely known as an investigator in fruit production and an authority on fruit nomenclature.

**Joint U. S. D. A.-Land-Grant College Policy Committee.**—A joint committee representing the U. S. Department of Agriculture and the Association of Land-Grant Colleges and Universities has been appointed by Secretary of Agriculture Clinton P. Anderson and Dean T. P. Cooper, president of the association. The purpose of this committee is to study cooperative extension policies and programs in view of the needs for additional educational services in agriculture and home economics. President Emeritus Walter C. Coffey, University of Minnesota, is to serve as chairman of the committee, the remaining members being Dr. Edmund deS. Brunner, professor of rural sociology, Teachers College, Columbia University; P. V. Cardon, U. S. D. A. Agricultural Research Administration; President Herman L. Donovan, University of Kentucky; President Roy M. Green, Colorado State College; President John A. Hannah, Michigan State College; President John R. Hutcheson, Virginia Polytechnic Institute; W. A. Minor, Assistant to the Secretary, U. S. Department of Agriculture; Thomas E. Wilson, chairman of the board of Wilson and Company; and David Meeker, manager of education for Harry Ferguson, Inc.

**National Advisory Research Committee.**—The advisory committee provided for in the Research and Marketing Act of 1946 (E. S. R., 95, p. 448) has been named by Secretary of Agriculture Clinton P. Anderson as follows: H. E. Babcock, chairman of the board of trustees of Cornell University; Fred Bailey, legislative counsel for the National Grange; Robert R. Coker, vice president of Coker's Pedigreed Seed Company, Hartsville, S. C.; John H. Davis, executive secretary of the National Council of Farmer Cooperatives; Charles F. Kettering, general manager of the Research Laboratory Division, General Motors Corporation; C. W. Kitchen, executive vice president of the United Fresh Fruit and Vegetable Association; Albert K. Mitchell, manager and co-owner of the 470,000-acre Bell Ranch located in New Mexico; James G. Patton, president of the National Farmers Union; Walter L. Randolph, president of the Alabama Farm Bureau Federation; H. J. Reed, dean of the Purdue University School of Agriculture and director of the Indiana Experiment Station and the department of agricultural extension; and Kerr Scott, North Carolina State Commissioner of Agriculture. The act specifies that the Secretary of Agriculture shall be chairman of the committee.

**Tobacco Research Stations in India.**—According to a recent note from the American Consulate in Calcutta, a number of research stations are being opened. These include one at Rajahmundry for cigarette tobacco, one at Anand for Bidi tobacco, and a central research station for all types at Guntur in Madras.

## RECENT WORK IN AGRICULTURAL SCIENCE

---

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

**Currents in biochemical research**, edited by D. E. GREEN (*New York 3: Interscience Pubs., 1946, pp. 486+, illus. 8*).—This treatise "represents an attempt by some 30 research workers to describe in as simple language as possible the important developments in their own fields and to speculate a little on the most likely paths of future progress." The articles are as follows: The Gene and Biochemistry, by G. W. Beadle (pp. 1-12); Viruses, by W. M. Stanley (pp. 13-23); Photosynthesis and the Production of Organic Matter on Earth, by H. Gaffron (pp. 25-48); The Bacterial Cell, by R. J. Dubos (pp. 49-60); The Nutrition and Biochemistry of Plants, by D. R. Hoagland (pp. 61-77), (Calif. Expt. Sta.); Biological Significance of Vitamins, by C. A. Elvehjem (pp. 79-88), (Univ. Wis.); Some Aspects of Vitamin Research, by K. Folkers (pp. 89-107); Quantitative Analysis in Biochemistry, by D. D. Van Slyke (pp. 109-121); Enzymic Hydrolysis and Synthesis of Peptide Bonds, by J. S. Fruton (pp. 123-135); Metabolic Process Patterns, by F. Lipmann (pp. 137-148); Biochemistry From the Standpoint of Enzymes, by D. E. Green (pp. 149-164); Enzymic Mechanisms of Carbon Dioxide Assimilation, by S. Ochoa (pp. 165-185); Hormones, by B. A. Houssay (pp. 187-206); Fundamentals of Oxidation and Reduction, by L. Michaelis (pp. 207-227); Mesomeric Concepts in the Biological Sciences, by H. M. Kalckar (pp. 229-240); Viscometry in Biochemical Investigations, by M. A. Lauffer (pp. 241-260); Isotope Technique in the Study of Intermediary Metabolism, by D. Rittenberg and D. Shemin (pp. 261-276); Mucolytic Enzymes, by K. Meyer (pp. 277-290); Some Aspects of Intermediary Metabolism, by K. Bloch (pp. 291-304); The Steroid Hormones, by G. Pincus (pp. 305-320); Plant Hormones and the Analysis of Growth, by K. V. Thimann (pp. 321-333); Chemical Mechanism of Nervous Action, by D. Nachmansohn (pp. 335-356); Some Aspects of Biochemical Antagonism, by D. W. Woolley (pp. 357-377); Chemotherapy—<sup>1</sup>Applied Cytochemistry, by R. D. Hotchkiss (pp. 379-398); Biochemical Aspects of Pharmacology, by A. D. Welch and E. Bueding (pp. 399-412); Some Biochemical Problems Posed by a Disease of

<sup>1</sup> The publications abstracted in these columns are seldom available for distribution by the Office of Experiment Stations. In general, application should be made to the Office of Information of the U. S. Department of Agriculture, Washington 25, D. C., for publications of the Department; to the directors of the State agricultural experiment stations, as listed on page 3 of the cover of this issue, for publications of the several experiment stations; and to publishers of books and journals for material issued by them. Microfilms and photo-static copies, the latter legible without magnifying equipment, may be purchased from the Library, U. S. Department of Agriculture, Washington 25, D. C. Rates and other details will be supplied by the Library on request.

Muscle, by C. L. Hoagland (pp. 413-425); Physiology and Biochemistry, by C. H. Best (pp. 427-438); X-Ray Diffraction and the Study of Fibrous Proteins, by I. Fankuchen and H. Marks (pp. 439-452); Immunochemistry, by M. Heidelberger (pp. 453-490); Social Aspects of Nutrition, by W. H. Sebrell (pp. 461-472); and Organization and Support of Science in the United States, by L. C. Dunn (pp. 473-486).

**Advances in enzymology and related subjects of biochemistry, VI**, edited by F. F. NORD (*New York 3: Interscience Pubs., 1946, vol. 6, pp. 563+, about 50 illus.*).—This series was initiated for publishing critical reports abutting on the borderland between physiology, chemistry, microbiology, and physical chemistry; continued participation in keeping abreast of this vast subject has again (E. S. R., 94, p. 147) resulted in a volume which—as has been the endeavor since its inception—"approaches the true polis of the enzymologist." The following papers are included, with bibliographies at the end of each. The Bacterial Amino Acid Decarboxylases, by E. F. Gale (pp. 1-32); Enzyme Problems in Relation to Chemotherapy. "Adaptation," Mutations, Resistance, and Immunity, by M. G. Segal (pp. 33-127); Biological Antagonisms Between Structurally Related Compounds, by D. W. Woolley (pp. 129-146); Adenosinetriphosphatase Properties of Myosin, by V. A. Engelhardt (pp. 147-191); States of Altered Metabolism in Diseases of Muscle, by C. L. Hoagland (pp. 193-230); Acetyl Phosphate, by F. Lipmann (pp. 231-267); Microbial Assimilations, by C. E. Clifton (pp. 269-308); Chemical Changes in the Harvested Tobacco Leaf—Part I. Chemical and Enzymic Conversions During the Curing Process, by W. G. Frankenburg (pp. 309-387); The Actions of the Amylases, by R. H. Hopkins (pp. 389-414); The Amylases of Wheat and Their Significance in Milling and Baking Technology, by W. F. Geddes (pp. 415-467); and Tocopherol Interrelationships, by K. C. D. Hickman and P. L. Harris (pp. 469-524). Author and subject indexes and a cumulative index to volumes I-VI are provided.

**Enzymes and their role in wheat technology**, edited by J. A. ANDERSON (*New York 3: Interscience Pubs., 1946, pp. 371+, about 40 illus.*).—This volume, the first of a series of monographs sponsored by the American Association of Cereal Chemists, deals with enzymes because of the important part they play in wheat technology and the rapid progress that has recently been made in our knowledge of them. Only the enzymes of the greatest interest to the cereal chemists are here treated, with a broad review of existing knowledge of each class and a discussion of what is known of the part played by the enzymes in wheat technology. The topics covered in the several chapters are as follows: The General Chemistry of Enzymes, by W. M. Sandstrom (pp. 1-21) (Univ. Minn.); Amylases, by M. L. Caldwell and M. Adams (pp. 23-58); Applications of the Amylases in Milling and Baking Technology, by E. Kaen and R. M. Sandstedt (pp. 59-126) (Univ. Nebr.); Esterases, by H. E. Longenecker (pp. 127-152); Esterases in Relation to Milling and Baking, by B. Sullivan (pp. 153-174); Oxidizing Enzyme Systems, by E. S. C. Barron (pp. 175-214); Oxidizing Enzyme Systems of Wheat and Flour, by B. Sullivan (pp. 215-230); Proteases, by A. K. Balls and M. W. Kies (pp. 231-273) (U. S. D. A.); Role of Proteases in Baking, by F. C. Hildebrand (pp. 275-294); The Mechanism of Alcoholic Fermentation, by C. H. Werkman (pp. 295-320) (Iowa State Col.); and Yeast Fermentation, by L. Atkin, A. S. Schultz, and C. N. Frey (pp. 321-352).

**Physical methods of organic chemistry, II**, edited by A. WEISSBERGER (*New York 3: Interscience Pubs., 1946, vol. 2, pp. 737-1367+, illus. 234*).—This second volume of methods for the observation of the physical properties of organic compounds continues the plan of treatment adopted in volume I (E. S. R., 94, p. 145), containing articles of the proportions and nature of small monographs on Spec

troscopy and Spectrophotometry (pp. 737-821), and Colorimetry, Photometric Analysis, and Fluorimetry (pp. 823-867), both by W. West; Polarimetry, by W. Heller (pp. 869-955); Determination of Dipole Moments, by C. P. Smyth (pp. 959-1009); Conductometry, by T. Shedlovsky (pp. 1011-1150); Potentiometry, by L. Michaelis (pp. 1051-1114); Polarography, by O. H. Müller (pp. 1115-1211); Determination of Magnetic Susceptibility, by L. Michaelis (pp. 1213-1247); Determination of Radioactivity, by W. F. Bale and J. F. Bonner, Jr. (pp. 1249-1289); and Mass Spectrometry, by D. W. Stewart (pp. 1291-1314): followed by a detailed subject index (52 pages) for the two volumes.

**Electrophoretic investigation of peanut proteins, I, II.** (U. S. D. A.) (*Arch. Biochem.*, 7 (1945), No. 3, pp. 475-489, illus. 4; 8 (1945), No. 2, pp. 239-249, illus. 4).—Of the two opening papers of this series, the first is concerned with the indications of electrophoretic analyses as to the protein components present and their approximate percentages, whereas the second, in addition to further electrophoretic observations, includes some notes on possible industrial applications of peanut protein preparations.

I. *Peanut meal extract, arachin, and conarachin*. G. W. Irving, Jr., T. D. Fontaine, and R. C. Warner.—Electrophoretic analysis of an extract believed to contain at least 98 percent of the protein of peanut meal indicated the presence of two major protein components which occur in the approximate ratio of 7:1, and which, together, comprise approximately 87 percent of the protein in the extract. The remaining 13 percent of the protein in the extract is held probably to consist of at least two minor protein components present in approximately equal amounts. Arachin, which comprises approximately 63 percent of the protein of peanut meal, was found to consist only of the two major protein components, the proportions being approximately 76 percent of the electrophoretically faster moving component (A) and approximately 24 percent of the slower moving component (B). Arachin was found to contain none of the minor protein components of the meal. Conarachin, which comprises approximately 33 percent of the protein of peanut meal, was found to consist of approximately 80 percent of component A, 20 percent of the minor components, and apparently none of the B component. The protein which remained after the successive removal of arachin and conarachin from a peanut meal extract consisted largely, if not exclusively, of the minor protein components and comprised approximately 3 percent of the protein of the meal. This protein fraction was isolated and found to contain 2.9 percent sulfur, a particularly high sulfur content for a vegetable protein. Deductions made from the results presented and from published analytical data indicated that the high-sulfur fraction may contain relatively large amounts of methionine and, possibly, large amounts of hydroxy-amino acids other than serine and threonine.

II. *Composition of several peanut protein fractions*, T. D. Fontaine, G. W. Irving, Jr., and R. C. Warner.—The electrophoretic analysis of several protein fractions obtained by simple precipitation procedures from slightly alkaline extracts of peanut meal is presented.

A fraction which comprised approximately 90 percent of the total protein of peanut meal, obtained by adjusting a slightly alkaline extract of peanut meal to pH 4.5, was shown to contain approximately 99 percent of the major protein components and approximately 58 percent of the minor protein components of the meal. "Although this fraction is not truly representative of the total protein of the peanut, it is, nevertheless, more nearly representative than is either arachin or conarachin, each of which is completely deficient in one of the protein components of the meal." A protein fraction nearly identical electrophoretically with that obtained by precipitation at pH 4.5 could be obtained by precipitation at pH 6.0. This fraction exhibited plastic properties not possessed by the fraction

precipitated at pH 4.5. The protein which remained in solution after the removal of the fraction precipitable at pH 6.0 could be precipitated by adjusting the solution to pH 4.5. The protein fraction thus obtained had a quantitative electrophoretic composition which was markedly different from that of either of the other fractions described and from arachin and conarachin. A protein fraction which had a comparatively high sulfur content could be isolated from the mother liquor remaining after the removal of the protein precipitable at pH 4.5. The protein of this fraction was shown electrophoretically to be composed almost exclusively of the minor protein components of the peanut and is a readily available source of material for the investigation of these sulfur-rich vegetable proteins.

The electrophoretic composition and physical properties of these fractions and the high yields with which they could be obtained strongly suggested the applicability of certain of these fractions in food products or in the preparation of adhesives, fibers, and other industrial materials.

**Improvement in the color of peanut and cottonseed proteins,** T. D. FORTAINE, S. B. DETWILER, JR., and G. W. IRVING, JR. (U. S. D. A.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1232-1236, illus. 3).—Protein preparations as light in color as commercial samples of soybean protein or lighter than these could be obtained from the meals of white-skin peanuts and blanched red-skin peanuts, without the use of bleaching agents. The color of proteins prepared from meals of unblanched red-skin peanuts and cottonseed was improved considerably through the use of controlled protein extraction and precipitation technics and by washing and the moist protein precipitates with organic solvents such as dioxane, acetone, and methyl ethyl ketone. By following procedures here given it was possible to obtain from meal of unblanched red-skin peanuts and from cottonseed meal satisfactory yields of protein preparations lighter in color than those obtained heretofore from similar raw materials. These preparations approached in color very near to the range of practical usefulness for the production of adhesives and fibers. The use of heat in drying was shown to exert inappreciable influence upon the color of dried peanut protein.

**Zein fibers: Preparation by wet spinning,** C. B. CROSTON, C. D. EVANS, and A. K. SMITH. (U. S. D. A.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12 pp. 1193-1198, illus. 6).—A new method for producing textile fibers from zein and the equipment used in the process are described. Zein fibers which had high tensile strength and wool-like properties were produced from alkaline dispersions of zein. The spinning dispersions were formulated to give a product of high viscosity by the use of denaturing agents, such as alcohol or urea, or by aging the solutions. The filaments were coagulated in an acid bath in which salts may or may not be used. The coagulated filaments were given a mild formaldehyde precure prior to stretching and drying. The influence of the extent of precure on the load-elongation properties of the fiber and on fiber strength was determined. Shrinkage and water resistance of the fibers were controlled by acetylation followed by a strong formaldehyde treatment.

**The protein-formaldehyde reaction: The question of methylene bridges and the unreactivity of benzoyl-d (—)-alanine toward formaldehyde,** D. C. CARPENTER. (N. Y. State Expt. Sta.). (*Arch. Biochem.*, 9 (1946), No. 2, pp. 159-164, illus. 1).—In extension of a considerable number of previous investigations of the nature of both stable and unstable combinations of formaldehyde with proteins and amino acids (E. S. R., 95, p. 2), the author here discusses calculations of bond distances which show that methylene groups cannot be expected to bridge the distance found by X-ray diffraction methods between parallel peptide chains in proteins. Specifically, the methylene group is shown to be capable of bridging

a distance of no more than 2.40 a. u. between nitrogen atoms, 2.52 a. u. between carbon atoms, or 2.46 a. u. between a nitrogen and a carbon atom, whereas the X-ray data show the distance between peptide chains to be 4.5 a. u. It was further observed that experiment carried out with benzoyl-*d* (—)-alanine showed no indication of reaction between the imino group of the —CCNH linkage and formaldehyde; a reaction which would be a necessary prelude to the formation of methylene bridges between peptide chains.

**An electrophoretic analysis of changes produced in blood serum and plasma proteins by heat in the presence of sugars,** C. R. HART, I. F. HUDDLESON, and C. D. BALL. (Mich. Exp. Sta.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 211–220, illus. 15.)—*d*-Glucose inhibited the formation of the C component when bovine plasma was heated under conditions that caused its formation in the absence of *d*-glucose. *d*-Galactose, *l*-arabinose, sucrose, *d*-fructose, lactose, *d*-mannitol, and *d*-xylose all showed some degree of inhibiting action against the C component formation in heated bovine serum. Aging in the presence of *d*-glucose did not alter the electrophoretic patterns of bovine plasma. Studies on bovine plasma fractions gave further evidence of the inhibiting action of *d*-glucose against C component formation but did not explain the mechanism of its formation. The C component was formed by heating an albumin- $\alpha$ -globulin fraction of bovine plasma.

**Studies on the enzymatic synthesis of dextran from sucrose,** E. J. HEHR. (Cornell Univ.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 221–233, illus. 2).—A bacterial enzyme which catalyzed the formation of a serologically reactive polysaccharide (dextran) from sucrose was obtained from sucrose broth cultures of a strain of *Leuconostoc mesenteroides* by a method which yielded preparations more potent than those previously available.

Analyses of enzyme-sucrose mixtures for each of the known reactants showed that the conversion of sucrose to dextran proceeded nearly to completion according to the equation,  $n$  sucrose  $\rightarrow$  dextran +  $n$  fructose. The concentration of sucrose influenced the initial activity of the dextran-synthesizing enzyme in the same way as it does invertase. The enzymatic synthesis of dextran simulated a first order reaction in systems containing 1 percent sucrose but resembled a zero order reaction in systems containing 5 percent sucrose. The corresponding unimolecular and zero order velocity constants can therefore be utilized to measure the activity of the enzyme. The addition of purified dextran to enzyme-sucrose mixtures did not increase the initial velocity of dextran formation. It is pointed out, however, that this observation does not exclude a possible activating effect of dextran, since small quantities of the preformed dextran, possibly sufficient to prime the reaction, were found regularly to accompany the active enzyme. A number of well-known enzyme inhibitors, including azide, cyanide, fluoride, and iodoacetate, were shown to be without effect upon the dextran-synthesizing enzyme.

**New methods of preparing invert sirup,** T. R. FREEMAN. (Fla. Expt. Sta.) (*Ice Cream Rev.*, 29 (1946), No. 10, pp. 48, 50, 58).—The author's observations on sucrose inversion noted above are here discussed in relation to their practical application in ice cream manufacture. Methods for the preparation of an invert sirup of high quality by the use either of phosphoric acid (at a cost, for the acid, of about 5 ct. per 100 lb. of sucrose) or of tartaric acid (at about 45 ct. per 100 lb. of sucrose inverted) are formulated, the required temperature (175° F.) being attainable in a pasteurizing vat. A practical advantage of this temperature over that of the boiling point of a heavy sugar solution (about 225°) lies in the fact that the lower-temperature inversion can be performed in equipment used for other work in the ice cream plant, whereas the higher-temperature steam kettles are usually not at hand or are of limited size. The phosphoric acid

method given calls for mixing 100 lb. of cane or beet sugar with 44 lb. of water. to which is added at the beginning of the heating 45 cc. of 85-percent phosphoric acid. The mixture is heated as quickly as possible to 175°, held during 1.5 hr. at this temperature, with the vat covered to prevent evaporation, and then added directly to the ice cream mix.

**The oxidative pathway of glucose decomposition** ([New York] Cornell Sta. Rpt. 1945, p. 108).—By means of preparations of the enzymes from *Micrococcus lysodeikticus*, the reactions involved in the initial stages of the oxidation of glucose by organisms not able to ferment this sugar were studied. The reactions established include, first, a phosphorylation of the glucose to glucose-6-phosphate; second, an oxidation of this phosphogluconic acid; third, an oxidation of this material to a ketophosphogluconic acid; and, fourth, decarboxylation of this compound to yield a pentose. The knowledge acquired with respect to the preparation of the necessary enzyme systems is believed sufficient to permit ascertaining the reactions involved in further stages of the oxidative process.

**Production of 2,3-butanediol from acid-hydrolyzed starch**, G. E. WARD, O. G. PETTJOHN, and R. D. COGHILL. (U. S. D. A.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1189–1194).—Acid-hydrolyzed starches fermented by *Aerobacter aerogenes* gave 13.5 to 14.0 lb. of 2,3-butanediol per 34 lb. of pure starch (equivalent to 1 bu. of corn). Proper balance in trace element content was important in determining the efficiency of the fermentation. Addition of manganese, cobalt, or molybdenum decreased butanediol production. Addition of copper or zinc improved the fermentation of some, but not all, samples. Treatments of starch hydrolyzates with an ion-exchange agent was generally effective in increasing the butanediol yield.

**The synthesis of isocitric acid**, G. W. PUCHER and H. B. VICKERY. (Conn. [New Haven] Expt. Sta.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 169–184).—The authors showed that the synthesis of isocitric acid by the hydrolysis of trichloromethylparaconic acid leads to a mixture of two diastereoisomeric forms in relative proportions of between 5:1 and 6:1, the racemic modification of the natural optically active acid being the predominating component. The method was modified in detail with improvement in yield. The synthesis of isocitric acid by the reduction of oxalosuccinic ester and subsequent hydrolysis led to a mixture of isomers in more nearly equal proportions. The separation of this mixture was difficult, and unsatisfactorily small yields of the lactone of the desired racemic acid were secured in pure form. Alloisocitric acid was obtained in small yield from the reaction products of both methods but was not successfully purified as the lactone. Derivatives of this isomer were shown to differ from the corresponding derivatives of the racemic modification of the natural acid.

Several derivatives of both isocitric lactone and of alloisocitric lactone are described. Of these, the *p*-bromophenacyl esters were shown to be useful both for characterization and for separation of the isomers. The neutral *p*-toluidine salt of isocitric lactone was found to have potentialities for the large-scale purification of this substance. Neither the trihydrazide of isocitric acid nor any of several pseudothiuronium sales of the lactones proved to be advantageous for characterization or for separation of the isomers.

**The antiinositol effect of  $\gamma$ -hexachlorocyclohexane**, S. KIRKWOOD and P. H. PHILLIPS. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 251–254, illus. 1).— $\gamma$ -Hexachlorocyclohexane inhibited the growth of the Gebrüder Mayer strain of *Saccharomyces cerevisiae*. This inhibition was found to be reversible by the addition of *i*-inositol. The other three known hexachlorocyclohexanes inhibited the growth of Gebrüder Mayer yeast to a slight degree, but this inhibition was not reversible by *i*-inositol. These data correlated closely with the

demonstrated ineffectiveness of the  $\alpha$ -,  $\beta$ -, and  $\delta$ -isomers as insecticidal agents. It is noted that the data suggest that the spatial configuration of the  $\gamma$ -isomer is similar to that of *i*-inositol and further support the hypothesis that the  $\gamma$ -isomer exerts its insecticidal action by interfering with the inositol metabolism of the insect.

**Production of methyl vinyl ketone from methylvinylcarbinol**, J. J. KOLFENBACH, E. F. TULLER, L. A. UNDERKOFLEB, and E. I. FULMER. (Iowa State Col.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1178-1180).—The authors describe a procedure for the catalytic vapor-phase oxidation of methylvinylcarbinol to give methyl vinyl ketone. The catalysts considered consisted of combinations of zinc oxide with cupric or cuprous oxide. The yields of methyl vinyl ketone were about 63 percent of theory under optimum conditions. With adequate equipment to control temperature rise during the reaction, the yields of methyl vinyl ketone would be considerably increased.

**Liquid-vapor equilibria in the acetylmethylcarbinol-water system**, R. H. BLOM and A. EFRON. (U. S. D. A.). (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1237-1240, illus. 4).—Liquid vapor equilibrium data for the acetylmethylcarbinol-water system at atmospheric pressure were determined. The acetylmethylcarbinol used was prepared from 2,3-butylene glycol by vapor-phase oxidation. The purification of the carbinol is described. The composition and boiling point of the acetylmethylcarbinol-water azeotrope at a pressure of 760 mm. were established.

**Rhodanese**, E. L. COSBY and J. B. SUMNER. (Cornell Univ.) (*Arch. Biochem.*, 7 (1945), No. 3, pp. 457-460, illus. 1).—This enzyme, occurring in kidneys and liver and capable of causing the synthesis of "rhodanate" or thiocyanate from hydrocyanic acid and sodium thiosulfate with simultaneous formation of sodium bisulfite, was concentrated about 100-fold by finely disintegrating 100 gm. of beef liver with 100 cc. of ice water, adding 24 cc. each of chloroform and of 95 percent alcohol, shaking vigorously, and centrifuging to remove much protein, dialyzing with continued maintenance of low temperature, and precipitating fractionally with ammonium sulfate in the presence of neutral phosphate, the final precipitate of the enzyme being dissolved in neutral phosphate buffer solution.

A method for the measurement of the activity of the enzyme is described, and certain errors in earlier conclusions as to the behavior of the enzyme are corrected.

**Densities of GR-S latices**, C. C. WINDING. (Cornell Univ.) (*Indus. and Engin. Chem.*, 37 (1945), No. 12, pp. 1203-1206, illus. 6).—A densitometer capable of indicating densities of unvented GR-S latices with an absolute accuracy of approximately 0.002 gm. per cubic centimeter is described. The design permits the instrument to operate over a wide range of pressures without affecting its accuracy. The present instruments have been constructed to withstand pressures of 100 to 150 lb. per square inch, but this range can be extended.

Complete data on samples of stripped and unvented GR-S latices of various degrees of conversion were obtained. Above 44.5 percent conversion the density of the unstripped samples increased linearly with conversion. The slope of this curve was 0.00114 gm. per cubic centimeter per percentage conversion, or 0.0035 gm. per cubic centimeter per percentage total solids. The data showed that below 45 percent conversion two phases were present. Above 25° C., the density of stripped latex of 75 percent conversion and of the unvented latices of various conversions decreased linearly with temperature. The rate of decrease for the stripped latex was approximately 0.0004 gm. per cubic centimeter per degree centigrade and for unvented latex, approximately 0.0006 gm. per cubic centimeter per degree centigrade.

**Enzymic nature of the carotene-destroying system of alfalfa,** H. L. MITCHELL and S. M. HAUGE. (Ind. Expt. Sta.) (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 7-14, illus. 3).—The authors discuss briefly the accumulated evidence of the existence in alfalfa of an oxidizing enzyme system largely responsible for the loss during field curing under good curing conditions of from 45 to 80 per cent of the original carotene content; and report upon an investigation of the time-temperature relationships involved in the inactivation of the carotene-destroying system by heat and projected to obtain additional data concerning the enzymic nature of the system.

The enzyme involved appeared to be a lipoxidase. It was partially or completely inactivated by heat, ethanol, copper sulfate, lead acetate, formaldehyde, pancreatin, sodium cyanide, thiourea, and sodium fluoride, but not by sodium sulfate and sodium chloride, and was salted out of solution by half saturation with ammonium sulfate. Its inactivation by heat was a function of both temperature and time. Maximum inactivation occurred in the plant tissue above 80° C. and in plant extracts above 70°, and virtually complete inactivation in the plant tissue was obtained at 90°-100° in less than 10 sec.

With reference to the practical application of the information obtained, it is noted that "the data on the relation of time and temperature to carotene preservation may be of importance to the engineer in the development of equipment for the production of alfalfa hay and leaf meal of high carotene content. To be of practical value, the heat treatment must be of short duration. This period of treatment may be less than 10 sec. at 90°-100° if the heat transfer is efficient. However, preliminary experiments in this laboratory showed that inactivation could not be obtained by subjecting the plant tissue for short periods of time to a stream of air heated to 200°. The evaporation of water prevented the leaves from reaching the temperature necessary for inactivation of the enzyme. Therefore, in the design of the equipment, consideration should be given to methods for the effective transfer of heat to the tissue."

**The function of B vitamins** ([*New York*] *Cornell Sta. Rpt.* 1945, p. 109).—In an investigation of the action of pyridoxine and its analogs, the coenzyme which is the active form of this vitamin was synthesized and shown to be pyridoxal phosphate. It was shown that the coenzyme when recovered in the pure state was most active in the enzyme systems studied than was pyridoxal, which had been used as a standard for assaying the coenzyme. The function of this coenzyme, termed codecarboxylase, was extended to five amino acids. This coenzyme was also shown to function in transamination. In the conversion of the pyridoxine, pyridoxal, and pyridoxamine to codecarboxylase by growing cells and resting cells, those forms which serve as vitamin B<sub>6</sub> for a given organism were shown to be converted to codecarboxylase.

**Function of the vitamin B<sub>6</sub> group: Pyridoxal phosphate (codecarboxylase) in transamination,** H. C. LICHSTEIN, I. C. GUNSALUS, and W. W. UMBRETT, (Cornell Univ.). (*Jour. Biol. Chem.*, 161 (1945), No. 1, pp. 311-320, illus. 3).—Methods for growing cells of *Streptococcus fecalis* R with highly active transaminase enzymes were devised, and the enzymes were obtained in dried cell preparations and in a water-clear, cell-free condition.

Pyridoxal phosphate, previously shown to function as the coenzyme of amino acid decarboxylases, was shown to function as the coenzyme of the glutamate-aspartate transaminase. This was accomplished (1) by growing cells in a medium deficient in pyridoxal to yield transaminase apoenzyme and activating the enzyme with synthetic pyridoxal phosphate; (2) by resolving the cell-free enzyme from organisms grown with pyridoxal and restoring the activity of this apoenzyme with pyridoxal phosphate. The function of the vitamin B<sub>6</sub> group in protein

metabolism is therefore at least partially explained as that action in amino acid decarboxylation and in transamination.

**The function of pyridoxine:** Conversion of members of the vitamin B<sub>6</sub> group into codecarboxylase, W. D. BELLAMY, W. W. UMBREIT, and I. C. GUN-SALUS. (Cornell Univ.). (*Jour. Biol. Chem.*, 160 (1945), No. 2, pp. 461-472, *illus.* {}.)—The authors show that the known members of the vitamin B<sub>6</sub> group are converted into codecarboxylase by micro-organisms capable of utilizing them as a source of vitamin B<sub>6</sub>. The efficiency of codecarboxylase formation by growing cells was found to be from 10 to 20 times as great as with cell suspensions or call preparations of *Streptococcus fecalis* R. Cell suspensions of *S. fecalis* R formed codecarboxylase from pyridoxamine in the presence of a keto acid. Organisms capable of growing without vitamin B<sub>6</sub> were shown to synthesize codecarboxylase. The codecarboxylase content of rat tissue was shown to be directly related to the pyridoxine level in the diet.

**Simple automatic control for vacuum systems**, J. J. SPADARO, H. L. E. VIX, and E. A. GASTROCK. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 3, p. 2, 4, *illus.* 1).—The device described and illustrated is a modification of a commercial form of Carteslan manostat designed to admit air to the system as needed to maintain the pressure reduction at a level constant to within  $\pm 0.25$  mm. by mechanical means involving no electrical connections. A floating bell tube in mercury is so arranged that the reduction in pressure inside and outside the bell is the same until the desired pressure reduction has been attained, but the interior of the bell is then shut off from the pumping system. Any further reduction of pressure thereafter raises the bell against the stem of a leakage valve, holding this open until air sufficient to restore the required pressure has been admitted.

**Reaction vessel for maintaining constant pH by continuous electrometric titration during sodium amalgam reductions**, N. SPERBER and D. R. BRIGGS. (Univ. Minn.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 74-75, *illus.* 2).—An electrode chamber is sealed onto the side of a three-necked reaction flask, a disk 3 cm. in diameter and perforated with numerous holes from 1 to 2 mm. in diameter separating the reaction vessel proper from the electrode vessel. From the lowest point of the electrode vessel a tube providing the main return for mercury leads to the main body of the reaction vessel at a point about 1 cm. above bottom. A second return tube, for the aqueous solution of the reactants, leads from the middle of one side of the electrode vessel downward to an opening into the reaction vessel about one-third of its height from the bottom and has a short section within the reaction vessel and turned into the direction of movement of the rapid and power-mechanical stirrer. Reduction of pressure by the rapidity of motion of the reaction flask contents at this point causes a circulation of the flask contents through the perforated disk into the electrode chamber and back to the reaction flask. Acid or alkali, as required to correct the change in pH in the course of the reaction, is added from a burette as needed to hold the reading of a pH meter connected to the electrode as nearly as possible to the selected pH value. It was shown to be possible to control the pH value in a constantly changing reaction mixture within a range of from 0.5 to 1 pH unit. Construction of the apparatus is described and illustrated by a drawing, and details of its operation are given.

**Laboratory study of continuous vegetable oil extraction: Countercurrent extractor, rising-film evaporator, and oil stripper**, A. C. BECKEL, P. A. BELTER, and A. K. SMITH. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 56-58, *illus.* 3).—Apparatus useful for studies of continuous vegetable oil extraction in the laboratory are described. These consist of a

continuous countercurrent extractor capable of supplying essential data, such as completeness of oil extraction, contact time, solvent-to-solid ratio, miscella composition, and solvent carry-over; a rising-film evaporator of the natural circulation type provided with a separator for continuous oil removal; and a new and efficient oil stripper providing turbulence and then films by operating against gravity and against surface tension.

**The succulometer, an instrument for measuring the maturity of raw and canned whole kernel corn,** A. KRAMER and H. R. SMITH. (Md. Expt. Sta.) (*Canner*, 192 (1946), No. 24, pp. 11-13, illus. 3; *Food Packer*, 27 (1946), No. 8, pp. 56, 58, 60, illus. 3).—The instrument described makes possible the measurement of the maturity of corn, based on the quantity of extractable juice, to give results equal in accuracy to a reliable moisture test on the raw product and the alcohol insoluble solids test on the canned product. A table is given showing the relation-ship of the succulometer values to the maturity tests—very young fancy whole kernel corn (raw), which would produce at least 23 cc. of extractable juice, should yield 20 cc. in the final product. Similarly, raw corn for an extra standard product should produce about 20 cc. of extractable juice, and the canned product should not fall below 16 cc.; raw corn yielding only 13 cc. of extractable juice would be dangerously close to the substandard level. Simple to operate and construct, the results from the test are obtainable in a few minutes' time.

**Di- and triethylene glycols as manostat fluids,** W. J. HUNCKEL and D. M. OLDRYD. (U. S. D. A.) (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 80-81).—It is noted that precision fractionations may extend over periods of a month or more and require, therefore, not only a very precise pressure control but also freedom from difficulties interrupting the operation; and that sulfuric acid, either concentrated or diluted to a specific gravity of 1.71, is corrosive, hygroscopic, and readily fouled by grease from the stopcocks. Both diethylene glycol and triethylene glycol are readily available, and both were found superior to sulfuric acid as manostat fluids. Both these glycols have sufficient electrical conductivity to operate a highly sensitive electronic relay, but when they are used with a less sensitive thermionic relay a drop of concentrated sulfuric acid must be added to provide sufficient conductivity. The specific gravities, viscosities, boiling points, and vapor pressures of the two glycols discussed are compared in a table with those of 75 percent and 80 percent sulfuric acid and of mercury.

**Experimental dryer for pre-pilot plant studies,** D. A. COLKER. (U. S. D. A.) (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 71-73, illus. 3).—The experimental unit described uses an air-circulation method of drying in which heated air is forced at high velocity through a bed of the material to be dried, supported upon perforated metal. A feature of the device is the control of the proportion of fresh to recirculated air and of steam supplied to the air-heating coils by a wet-bulb and dry-bulb recorder controller.

**Colorimetric determination of nitrites,** B. F. RIDER and M. G. MELLON. (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 2, pp. 96-99, illus. 3).—Spectrophotometers of two types were used to determine the effects of reagent concentration, order of addition of reagents, pH, temperature, light, nitrite concentration, and the presence of 63 diverse ions on the reddish purple coloration produced by 4-aminobenzenesulfonic acid (sulfanilic acid) and 1-aminonaphthalene ( $\alpha$ -naphthylamine) in the presence of nitrous acid. It was shown that reliable determinations can be made in the range of 0.025 to 0.600 p. p. m. of nitrite ion in a 2-cm. cell, and that as little as 0.0005 p. p. m. of nitrite nitrogen can be determined by the use of 24-cm. Nessler tubes. Time

had to be allowed for complete diazotization before the coupling agent was added. Diazotization was carried out in strongly acidic solution at room temperature in diffuse light, and the system was buffered to pH 2.0 to 2.5 for coupling.

**Titrimetric determination of sulfate in natural waters and soil extracts,** E. C. CANTINO. (Univ. Calif.). (*Soil Sci.*, 61 (1946), No. 5, pp. 361-368, illus. 2).—The author reviews conclusions of previous investigators to the effect that methods based on precipitation of sulfates by an acid solution of barium chromate followed by determination of the released chromate, which remains soluble in alkaline solution, are usually inaccurate. He adds his observation in repeated experiments, that analysis of residual chromate left in solution after simultaneous removal of barium chromate and barium sulfate seldom yields results which coincide with the absolute concentration of sulfate originally present. "Extensive investigations indicate conclusively, however, that with proper control of the procedure, results established by titrimetric analysis are a function of the original sulfate content within relatively wide limits." Upon this basis, the author elaborated an empirical, rapid method of analysis for sulfate in waters in which sulfate is precipitated with an acid solution of barium chromate, excess barium is eliminated by alkalization, and residual chromate is determined by titration with thiosulfate of the iodine set free from potassium iodide by the chromate. The actual sulfate content was found to be a function of the thiosulfate titer, and an evaluation of the sulfate concentration could be made either by comparison with a standard curve or by formula.

**On the determination of plasma iodine,** A. TAUBOG and I. L. CHAIKOFF. (Univ. Calif.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 313-322, illus. 1).—The authors tested the Chaney method<sup>2</sup> for the determination of plasma iodine content by means of the radioactive iodine isotope,  $I^{131}$ . With a few modifications this procedure was found to yield satisfactory results for the determination of iodine, not only in 3 cc. of plasma but also in small amounts of thyroid tissue and in dietary mixtures. Organic material was digested with a mixture of chromic and sulfuric acids, a process that oxidized iodine to nonvolatile iodic acid. The latter, together with the excess chromic acid was reduced with phosphorous acid, and the volatile iodine formed thereby was distilled and trapped in an alkaline solution. The iodine was then measured by its catalytic effect on the reduction of ceric sulfate by arsenious acid.

Values for total and protein-bound iodine of plasma of several species are reported. The levels of protein-bound iodine in the plasma of dog, rat, mouse, and domestic fowl were found to be quite similar (3% to 4% percent). The proportions contained in human plasma were appreciably higher (5% to 8% percent).

**The determination of thyroxine in the thyroid gland of the rat,** A. TAUBOG and I. L. CHAIKOFF. (Univ. Calif.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 323-328).—The fresh glands were hydrolyzed in 2 N sodium hydroxide solution, the hydrolysates were neutralized and adjusted to a pH value between 3.5 and 4, and the thyroxine was extracted by a butyl alcohol method. Nonthyroxine iodine compounds were removed from the butyl alcohol thyroxine solution by treatment with a specified aqueous alkaline solution, the butyl alcohol was completely removed from the thyroxine extract by heating at from 50° to 60° C. under reduced pressure in a stream of carbon dioxide, and the iodine content of the residue was determined by the method noted in the preceding abstract. In the aqueous layers from the butyl alcohol extraction and the purification of the butyl alcohol extract, the nonthyroxine iodine content of the glands was also determined.

<sup>2</sup> Indus. and Engin. Chem., Analyt. Ed., 12 (1940), No. 3, pp. 179-181, illus. 3.

**Estimation of iodine color of starches and starch fractions**, S. A. WATSON and R. L. WHISTLER. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 75-76).—Thirty mg. of starch are dispersed in 10 cc. of 1 N potassium hydroxide by allowing the mixture to stand with occasional shaking at 0° C. for 1 to 2 hr. For starch in the whole-granule state, 20 cc. of 0.5 N potassium hydroxide are used for the dispersion. The dispersion is neutralized with 1 N hydrochloric acid to a phenolphthalein end point and 1 drop of acid added in excess. The solution (pH 4 to 6) is then made up to 100-cc. volume, giving a starch concentration of 0.03 percent. By this procedure a constant quantity of salt is introduced into each sample. Large proportions of salt, which produce changes in the iodine color, are to be avoided. To 10 cc. of the solution in a 16- by 150-mm. test tube is added 0.5 cc. (10 drops) of 0.01 N iodine solution ( $KI=0.014\text{ M}$ ) dropwise, with shaking. After 0.1 cc. (2 drops) has been added, the color of the solution is observed. At this point, the presence of small amounts of amylose in amylopectin will be evidenced by a blue color. The remainder of the 0.5 cc. of iodine is then slowly added and the color again observed. Further addition of iodine is unnecessary and in some cases may vitiate the color test by superimposing of the color of free iodine on the starch-iodine color. All observations of color are made by transmitted daylight of a daylight fluorescent lamp and colors compared to the standard color chart.

Colors observed in the application of the iodine test in this form to starches, starch fractions, and starch derivatives are described in terms of the Ridgeway color chart names and of the Munsell numerical notation.

**Anomalous behavior of methyl 12-hydroxy-9,10-octadecenoates in rapid iodine number determinations**, P. S. SKELL and S. B. RADLOVE. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 67-68).—The authors showed that the methyl esters of ricinoleic, ricinelaidic, and O-propionylricinoleic acids quantitatively add iodine chloride from Wijs reagent in less than 1 min. However, when mercuric acetate was present, methyl ricinoleate and ricinelaidate reacted with additional halogen, thus giving high iodine values, whereas the methyl O-propionylricinoleate behaved normally. This anomalous effect was shown to be due to the presence of the free hydroxyl group.

**Viscosimetric determination of thymonucleodepolymerase**, M. LASKOWSKI and M. K. SEIDEL. (Univ. Ark.) (*Arch. Biochem.*, 7 (1945), No. 3, pp. 465-473, illus. 3).—A method for the quantitative determination of thymonucleodepolymerase is based on measurements of the change in viscosity of the reacting mixture. The reaction was found to be roughly of the first order, and the value of the velocity constant  $K$  was used for the determination of enzymic activity. Fairly good proportionality between the value of  $K$  and the amount of enzyme used was observed. The optimal pH of thymonucleodepolymerase was close to 7. The enzyme was activated by magnesium ions, optimal concentration being 0.025 M.

A proposed unit of thymonucleodepolymerase is defined as an amount of enzyme which will give the value of the velocity content  $K = (1/t) \log (\eta_0/\eta_t) = 1 \times 10^3$  when incubated with 25 mg. of thymonucleic acid (prepared according to Hammarsten) at 37° C., at pH 7 in 0.2 M borate buffer, made 0.025 M with respect to  $MgSO_4$ ; total volume of the reacting mixture 8 cc.; time of incubation 30 min.; readings at 5-min. intervals.

**Determination of tocopherol in plant tissue**, M. E. WALL and E. G. KELLEY. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 3, pp. 198-201, illus. 1).—In both of the two procedures here compared, dry plant materials were extracted with Skellysolve B, the alcohol then being removed. It was necessary to purify the sample before the final estimation could be made.

Chlorophyll and xanthophyll were separated from tocopherols by adsorption on a Supercel-activated magnesia column. Carotene and tocopherolquinones were then destroyed by treatment with 85 percent sulfuric acid.

In the first of the procedures compared, the tocopherols were transferred to ethanol solution, oxidized with nitric acid, and, after removal of ethanol-insoluble lipoids, determined with a photoelectric colorimeter at 480  $m\mu$ . In the alternative procedure the tocopherols were finally dissolved in chloroform, and reacted with the ferric chlorid- $\alpha$ -dipyridyl reagent. The pink ferrous dipyridyl complex was immediately transferred to aqueous solution to prevent further reduction of the iron by a slowly reducing fat-soluble compound. The colorimetric determination was carried out at 620  $m\mu$ . in a photoelectric colorimeter.  $E_{1\text{ cm.}}^{1\text{ percent}}$  and 450 and 520  $m\mu$ . values obtain by the two methods with synthetic and natural  $\alpha$ -tocopherols agreed within 5 percent. The values for natural  $\gamma$ -tocopherol were 10 percent lower by the first method and 35 percent lower by the second method. All these compounds were shown to be quantitatively eluted from a magnesia-Supercel adsorbent and showed a maximum loss of 5 percent when shaken with 85 percent sulfuric acid. Tests in which pure synthetic  $\alpha$ -tocopherol were added to the extracts and carried through the entire procedure showed an average recovery of 95 percent with both methods. In most cases the results obtained by the two procedures agreed within  $\pm 5$  to 10 percent.

**Determination of inorganic phosphorus in plant materials**, W. A. PONS, JR., and J. D. GUTHRIE. (U. S. D. A.) (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 3, pp. 184-186, illus. 1).—To provide a method of which the results would not be affected by large quantities of proteins or by color or turbidity in the extracts, the authors developed a procedure involving extraction of the inorganic phosphate with 0.75 N trichloroacetic acid, formation of the phosphomolybdate complex in the diluted trichloroacetic acid extract, extraction of the complex with isobutyl alcohol, development of the color by shaking the isobutyl alcohol extract with aqueous stannous chloride, dilution of the blue isobutyl alcohol solution to fixed volume with ethyl alcohol, and measurement of the color against that of a blank by means either of a photoelectric colorimeter or of a spectrophotometer. Color intensity increased slowly during 40 min., then remained constant for 19 hr.

**Determination of the cystine and methionine content of plant and animal material by a differential oxidation procedure**, R. J. EVANS. (Wash. Expt. Sta.). (*Arch. Biochem.*, 7 (1945), No. 3, pp. 439-445).—The author based a method for the determination of the cystine and methionine content of complex plant and animal products on the differential oxidation procedure of Blumenthal and Clarke (*E. S. R.*, 75, p. 294). The method used consisted of the determination of three sulfur fractions—total sulfur, inorganic sulfur, and the sulfur oxidized to sulfate by heating with concentrated nitric acid. It was shown that cystine sulfur is oxidized to sulfate but methionine is not oxidized by heating with nitric acid in the presence of considerable organic matter.

On the protein basis, the cereals, fish meals, and casein were the best sources of methionine studied, and the cereals, whey, fish meals, soybean oil meal, and cottonseed meal the best sources of cystine. Proteins of peas and the meat scrap were the poorest sources of both amino acids.

**Methionine determination in proteins and foods**, F. A. CSONKA and C. A. DENTON. (U. S. D. A.). (*Jour. Biol. Chem.* 163 (1946), No. 1, pp. 329-338, illus 3).—The wavelength of minimum transmission for the red compound formed by the action of sodium nitroprusside upon methionine was found to be 510  $m\mu$ . There was a stoichiometric relationship of approximately 2:1 between sodium nitroprusside and methionine in the absence of interfering substances;

but in the presence of other amino acids, especially glycine, the relationship no longer held good. The addition of glycine lessened, but did not eliminate, the interfering color formed by the action of the nitroprusside upon histidine; and glycine itself interfered so seriously, in the absence of a considerable excess of the nitroprusside, as to cause a 74 percent loss in the observed methionine value when 3 mg. of nitroprusside reacted with 1.5 mg. of methionine in the presence of 10 mg. of glycine. Removal of the histidine by precipitation with phosphotungstic acid permitted carrying out the determination without the addition of glycine. Other amino acids remaining in the test solution still invalidated the stoichiometric relationship observed in the treatment of pure methionine solutions with nitroprusside, but consistent methionine values were obtained when aliquots of the protein hydrolysate representing not more than 50 mg. of the protein material were treated with 10 mg. of the nitroprusside. The methionine values thus obtained were also in satisfactory agreement with those given by two other methods.

**A simplified extraction-distillation method for the determination of the volatile fatty acids of cheese.** K. L. SMILEY, F. V. KOSIKOWSKY, and A. C. DAHLBERG. (Cornell Univ.). (*Jour. Dairy Sci.*, 29 (1946), No. 5, pp. 307-315).—The method described is based on two distillations of acid cheese solution, one dealing with the fat phase and the other with the residual material. After ether extraction of the acid-cheese mixture, the volatile fatty acids were removed from the other with dilute alkali. The alkali rinses were heated to drive off the ether, then acidified, refluxed to remove carbon dioxide, and distilled in the presence of  $MgSO_4$ , until crystallization occurred. In the meantime, 250 cc. of distilled water were added to the residual material and the solution distilled until 280 cc. of distillate were collected. The sum of the titrations from the two distillations plus that of the alcohol rinse containing the water-insoluble volatile acids deposited in the condenser represented the total volatile acids of the cheese.

The results obtained by the new method agreed closely with those of previous procedure, and had the advantages of requiring no special apparatus, permitting a greater number of distillation per day and greatly reducing the time consumed in the analysis of a cheese sample. In the absence of nonvolatile acids, acetic, butyric, caproic, and caprylic acids were quantitatively recoverable by distillation in the presence of  $MgSO_4$ , as were also capric and lauric acids. Of myristic acid, 71 percent was recovered in such a distillation. Nonvolatile fatty acids, such as palmitic and oleic, exerted a retentive effect on caprylic, capric, lauric, and myristic acids during direct distillation in the presence of  $MgSO_4$ , the degree of retention being in direct relationship to the number of carbon atoms present in the volatile acids. When butyric and caproic acids were distilled, the nonvolatile acids exerted no retentive effect.

**Factors influencing estimation of free fatty acids in dried egg powders.** L. KLINE and C. M. JOHNSON. (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 35-38, illus. 1).—The authors note that at the normal pH of dried whole egg, fatty acids liberated during storage are incompletely estimated by the A. O. A. C. procedure for determination of acidity of the ether extract. In addition, the contribution of the extracted cephalin to the acidity of the ether extract may obscure significant percentage increases in the free fatty acidity of the egg powder. The necessity for drying the egg powder as required in the A. O. A. C. procedure is reemphasized. The incompleteness of extraction could be overcome by reconstituting, acidifying to pH 4.5, and drying the egg under reduced pressure while frozen before performing the fat extraction. Acetone precipitation served to remove the greater part of the cephalin. For the complete elimination of this source of error, alcoholic magnesium chloride could be used in conjunction with the acetone treatment.

**Determination of carotenoids and lipid amine-aldehyde products in dehydrated egg,** H. J. DUTTON and B. G. EDWARDS. (U. S. D. A.) (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946) No. 1, pp. 38-41, illus. 2).—A spectrophotometric method for the determination of carotenoid content and a fluorometric method for the determination of ether-soluble brown products in powdered eggs are described. The development of brown lipid substances in stored egg powders was found to introduce errors into the direct photometric measurement of carotenoids. These errors were minimized by the spectrophotometric procedure described, however. Both determinations could be performed upon a single ether extract of egg powder

**Chemical determination of vitamin A in dried whole eggs,** C. R. THOMPSON, M. A. EWAN, S. M. HAUGE, B. B. BOHREN, and F. W. QUACKENBUSH. (Purdue Univ.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946) No. 2, pp. 113-115).—"A chemical method is described for the determination of vitamin A in dried whole eggs by the use of chromatographic adsorption. After a sample is hydrolyzed with alkali and extracted with ethyl ether, the unsaponifiable fraction is adsorbed on a column of calcium hydroxide and the  $\beta$ -carotene, cryptoxanthol, vitamin A, luteol, and zeaxanthol bands are allowed to separate. The provitamins are eluted and determined separately. Antimony trichloride reagent is then added to the combined vitamin A and provitamin A eluates and the amount of blue color determined in a photoelectric colorimeter. Data presented on nine samples of dried eggs show that the values obtained by the chemical method agree within 10 percent with those obtained by bioassay."

**Vitamin retention in blanched carrots: Alcohol-insoluble solids as a reference base,** F. A. LEE. (N. Y. State Expt. Sta.) (*Indus. and Engin. Chem., Analyt. Ed.*, 17 (1945), No. 11, pp. 719-720).—Experimental results of a study of total solids, alcohol-insoluble solids, and carotene content of raw and blanched carrots are tabulated, together with calculated changes in carotene content as estimated from calculations on the dry weight basis and on the basis of alcohol-insoluble solids. The data show that alcohol-insoluble solids in the carrot are substantially unaltered by blanching in boiling water for periods of 5 to 20 min., whereas total solids progressively decrease (due to solution of water-soluble constituents) with increase in time. Accompanying the great decrease in total solids, the carotene content shows apparent increases when calculated on the dry basis. Expressed on the basis of alcohol-insoluble solids, however, carotene values are relatively constant. The use of alcohol-insoluble solids as a basis for calculating vitamin values for carrots is therefore recommended, and application of this method to other vegetables is suggested. The technic recommended for determining alcohol-insoluble solids involves extraction of the finely ground sample with 80-percent ethyl alcohol under reflux condenser for 30 min., followed by hot filtration through a tared sintered-glass crucible and washing of the residue with hot 80-percent alcohol until the residue is nearly white. Drying is accomplished in an air oven at a temperature of 95° C. for an overnight period.

**A comparison of four methods for studying the urinary excretion of thiamine,** H. H. GIFFT and H. M. HAUCK. (Cornell Univ.) (*Jour. Nutr.*, 31 (1946), No. 5, pp. 635-645).—"Four normal adults were maintained for 44 days on a controlled diet which was estimated to furnish 600  $\mu$ g. of thiamine per 1,000 calories. Basal 24-hr. urinary excretions of thiamine were higher at the first of the period than at the end. Supplements of thiamine given during the pre-experimental period undoubtedly caused elevations in values for the first 2 weeks of the study.

"Four urinary excretion tests for thiamine were studied. Values for 24-hr. excretions of thiamine for the last 4 weeks ranged from 100 to 224  $\mu$ g. per day.

Average percentages of thiamine intake excreted ranged from 9 to 13 percent. Responses to a 5-mg. oral test dose at the end of the study ranged from 15 to 22 percent recovery in 24 hr. Responses to 1-mg. intramuscular test doses toward the beginning of the study ranged from 15 to 24 percent recovery. At the end of the study they ranged from 5 to 21 percent recovery, or 193 to 403  $\mu$ g. excretion in 24 hr.

"When the urinary excretion values recorded for 'normal' subjects were used as standards for comparison, the nutritional status of these studies with respect to thiamine was not judged to be the same by all four criteria. More data are needed to establish the range of normal values for these urinary excretion tests and their relative sensitivity."

**A rapid microdetermination of glycogen in tissue slices**, W. J. VAN WAGEN-DONK, D. H. SIMONSEN, and P. L. HACKETT. (Oreg. State Col.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 301-306, illus. 1).—The authors describe a microcolorimetric method, adapted to the Klett-Summerson colorimeter, by means of which the glycogen content of samples of tissue slices (liver or kidney) or of muscle strip weighing from 50 to 75 mg. could be determined accurately by measurement of the color developed upon treatment of the glycogen with iodine. As it was possible to carry out both the precipitation of the glycogen and the development of the color in the colorimeter tube, only one transfer was necessary. In liver samples showing mean glycogen contents of 16.1 and of 0.65 percent, respectively, the determination showed standard errors of  $\pm 0.3$  and  $\pm 0.02$  percent, respectively. In 10 determinations of known quantities of glycogen added to liver slices, the average recovery was 101.6 percent. Good agreement with a standard method was obtained.

**Estimation of gossypol in cottonseed meal and cottonseed meats**, F. H. SMITH. (N. C. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 43-45, illus. 1).—The authors determined spectral absorption curves for the aniline derivative of pure gossypol and gossypol extracted from cottonseed meal and cottonseed meats with 60 percent alcohol containing ether in the Waring Blender, these curves representing the difference between the absorption spectra of the aniline derivative of gossypol and of gossypol or gossypol extracts at the same concentration. The absorption curve for the cottonseed meats extract as practically identical with that of pure gossypol except in the region of 380 to 410  $m\mu$ . The curve for the cottonseed meal extract was shifted slightly to the right but was very similar to that of pure gossypol. Cottonseed meal samples were extracted by allowing them to stand 10 min. in 30 percent alcohol, then adding sufficient 72 percent alcohol to give a 60 percent alcohol to which ether was added. After treatment for 5 min. in the Waring Blender, the extracts were filtered and made to 100 cc., and aliquots were taken for the blanks and determinations. The dianilino-gossypol color was developed in the latter by heating after adding aniline, then the percent transmittance was read in a Coleman spectrophotometer, from which the gossypol content was determined. It was concluded that "duplicate determinations of gossypol in cottonseed meal or cottonseed meats may be completed in 2 hr. with readily reproducible results."

**Spectrophotometric method for estimating gossypol in crude cottonseed oil**, F. H. SMITH. (N. C. State Col.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 41-43, illus. 1).—Spectral absorption curves of the dianilino derivative of pure gossypol and that of the gossypol in an expeller and hydraulic crude cottonseed oil are given. A rapid spectrophotometric method having an accuracy and precision approaching that of the gravimetric method for estimating the gossypol content of crude cottonseed oil is presented. The time required for the analysis is given as less than 2 hr.

**Determination of menthol in peppermint oil: Acetic anhydride and pyridine as reagent,** J. S. JONES and S. C. FANG. (Oreg. Expt. Sta.) (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 2, pp. 130-131).—A procedure very satisfactory with regard to rapidity and reproducibility of results was based upon the utilization of a mixture of acetic anhydride and pyridine. The necessary acetylation period was somewhat longer for menthol than was required by the microprocedure with the same mixture for other alcohols unaccompanied by such a mixture of compounds as that which characterizes peppermint oil. The requirement for acetic anhydride was at least 100 percent in excess of the theoretical quantity. Since the menthol content of peppermint oil varies with the several factors pertaining to production and time of harvesting, it was necessary to add a substantial excess of this reagent. The proportion of pyridine used could be varied within a rather wide range, but the ratio of acetic anhydride to pyridine could not be greater than 1 : 1. A wider ratio necessitated a longer acetylation period. For peppermint oils containing free acid, the values thus obtained should be corrected. The proposed procedure was found to be substantially less time-consuming than preceding acetylation methods for determining free menthol, more economical of reagents, and capable of yielding results more closely in agreement among themselves.

**Rapid photometric methods for determining rubber and resins in guayule tissue and rubber in crude-rubber products,** H. P. TRAUB (U. S. Dept. Agr., *Tech. Bul.* 920 (1946), pp. 37, illus. 16).—Rapid semimicrophotometric methods for the determination of rubber and resins in small samples of guayule tissue are described. These procedures could also be adapted for other rubber- and resins-bearing plants, and the analysis of synthetic rubbers, and were adapted for the determination of rubber in crude-rubber products.

The methods are based on the following principles: (1) Grinding the properly dried tissues or cutting the product to the required degree of fineness to permit quantitative extraction of rubber or resins; (2) using oxygenated solvents (ketones, acetates, etc., for rubber; and acetonylacetone, cellosolve, etc., for resins) with relatively high boiling points (115.8° to 230.7° C.), alone or in mixture, that permit the rapid extraction of rubber or resins in 20 to 30 min. at relatively high temperatures (115° to 120°); (3) precipitating the rubber or resins from aliquots of the solutions by means of suitable precipitants (acidified ethanol for rubber and acidified water for resins); (4) making photometric readings of percentage of light transmittance after rubber or resins precipitation at a wave length that eliminates the error due to extraneous color (the determination relying on the development of a uniform turbidity rather than a color for purposes of analysis); and (5) securing this uniform turbidity, or required degree of precision, by making the photometric readings at standing times (during which the readings are relatively stable) based on the concentrations of rubber or resins precipitated.

**Differentiation of rubber and gutta hydrocarbons in plant materials,** S. B. HENDRICKS, S. G. WILDMAN, and E. J. JONES. (U. S. D. A.). (*Arch. Biochem.*, 7 (1945), No. 3, pp. 427-438, illus. 3).—As comparison standards, the authors used rubber obtained from *Hevea brasiliensis* latex as the polymerized hydrocarbon of the cis-configuration, and balata gutta (from *Mimusops balata*) as a representative polymer of the trans-configuration. After removal of nonrubber substances by anaerobic bacterial action, the dried coagulum from the *Hevea* latex was several times dispersed in benzene and precipitated with acetone. The balata polymer was purified by first extracting a sheet of balata with hot water, then dispersing in benzene, centrifuging, precipitating with acetone, and recrystallizing from petroleum spirit. Compared in the infra-red wave-length range, these preparations

showed a clear-cut differentiation, the relative absorption coefficient of the rubber polymer being 42 percent greater at  $12\mu$  than was that of the gutta.

Hydrocarbons of the rubber (r) or gutta (g) types isolated from *H. brasiliensis* (r), *M. balata* (g), *Asclepius erosa* (milkweed (r)), *A. syriaca* (milkweed (r)), *Oenothera biennis* (evening-primrose (r)), *Solidago laciniata* (goldenrod (r)), *Eucommia ulmoides* (g), *Euonymus japonicus* (g), and *Jatropha* sp. (chilte (r)) were positively identified by their infra-red absorptions near  $12\mu$ . Mixed cis- and trans-isomers were absent in all cases even though the plants examined were selected as giving hydrocarbon polymers of questionable types.

**Chemical methods for analysis of dichloro-diphenyl-trichloroethane (DDT), J. M. GINSBURG.** (N. J. Expt. Stas.) (*Jour. Econ. Ent.*, 39 (1946), No. 2, pp. 174-177).—The principal reactions of eight chemical methods now being investigated for analyzing DDT in spray residues and insecticide mixtures are briefly reviewed.

**The determination of DDT: A review of analytical methods for the determination of DDT in the technical and pure compounds and in various insecticides, by total chlorine procedures, C. G. DONOVAN.** (U. S. D. A.). (*Soap and Sanit. Chem.*, 22 (1946), No. 6, pp. 165, 167, 201).

**Accelerated aging test for insecticidal aerosols containing DDT, L. D. GOODHUE and W. R. BALLINGER.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 2, pp. 131-132, illus. 1).—The authors note that the introduction of DDT into the liquefied-gas aerosol has created the problem of stabilizing the aerosol solution and preventing corrosion of the container. The ease with which hydrochloric acid is liberated from DDT in the presence of some iron salts has made necessary the development of an accelerated aging test for studying the effect of the different aerosol constituents on this reaction. A simple pressure test tube and a method of running a test are described. The rate of decomposition was found to vary greatly, depending mostly on the solvents used. Some of the solvent combinations studied appeared to be satisfactory.

**Quantitative determination of phenolic fungicides, S. GOTTLIEB and P. B. MARSH.** (U. S. D. A.). (*Indus. and Engin. Chem., Analyt. Ed.*, 18 (1946), No. 1, pp. 16-19, illus. 5).—The color reaction of 4-aminoantipyrine with the textile mildew-preventive 2,2'-methylenebis[4-chlorophenol] in the presence of potassium ferricyanide and dilute sodium carbonate was found adaptable to quantitative analysis for this phenolic material and was used for its determination in fabric. Absorption curves and standard calibration curves for several other commercially important phenols are given, with the suggestion that this color reaction may find application in the quantitative determination of many phenolic fungicides, germicides, and other materials.

The product of the reaction is represented as of an indophenol type, but it is pointed out that an apparently similar color formation takes place in reaction with phenols having the 4-position blocked. These instances may involve formation of an orthoquinoid structure.

**Biological stains: A handbook on the nature and uses of the dyes employed in the biological laboratory, H. J. CONN** (*Genera. N. Y.: Biotech Pubs.* 1946, 5. ed., rev., pp. 346, illus. 4).—In preparing this fifth edition of the work previously noted (E. S. R., 56, p. 163), the text has been largely rewritten. Cross references are given throughout the book to the loose-leaf manual *Staining Procedures Used by the Biological Stain Commission*,<sup>3</sup> thus rendering it easy to find

<sup>3</sup> H. J. Conn and M. A. Darrow. Geneva, N. Y.: Biotech Pubs., 1943, pt. 1, Sects. A-D, pp. [130]; 1944, pts. 2, Sects. A-B, pp. [32]; 3, Sects. A-B, pp. [39].

where to locate any detailed staining procedure in which any one of the dyes herein described is employed.

**Progress in the standardization of stains**, H. J. CONN (*Stain Technol.*, 21 (1946), No. 3, pp. 81-86).—This is a review of the 25 yr. of cooperation with the U. S. Department of Agriculture and includes the beginnings of stain investigations in the United States, organization of the work under the National Research Council, organization of the Stain Commission, and the early and more recent phases of the cooperation. The author expresses the "appreciation of the Commission to the Department of Agriculture for a quarter century of active and invaluable cooperation."

## AGRICULTURAL METEOROLOGY

**Trees in two climates**, W. H. CHANDLER (*Berkeley: Univ. Calif. Press; London: Cambridge Univ. Press*, 1945, pp. 22+).—A lecture on climatic factors in relation to the life of trees, including cold hardiness and the mechanisms of injury by low temperatures and of the chilling or other requirements for breaking the rest period in warm and cold climates. There are 33 references.

**Spring frosts with special reference to the frosts of May 1935**, W. R. DAY and T. R. PEACE ([*Gt. Brit.*] *Forestry Comm. Bul.* 18 (1946), 2, ed., pp. 111, illus. 41).—Experiences during the 9 yr. since the first edition of this bulletin was first published (*E. S. R.*, 78, p. 11) are said to confirm fully the importance of frost as a cause of disease in trees in Britain. The exotic conifers have continued to provide the more extreme examples of susceptibility among species of economic importance to forestry. It is believed that sufficient examples have been given to convince the reader that the relationship between topography, frost intensity, and damage to young trees is by no means simple. It is shown that topography, by checking or promoting the flow of cold air, plays an important role in regard to frost intensity; the degree of damage, however, often depends more on the developmental stage of the buds at the time of the frost than on the local air currents. The bud stage, in its turn, may be affected by aspect and degree of slope, thus bringing the argument back again to topography. Other factors, such as the relationship of slope to soil conditions, which in turn may affect the rate at which a young tree grows out of the frost zone, exposure to the morning sun, and shelter from the wind, must also be borne in mind. It is from the interaction of some or all of these factors that the cause of any given case of frost damage must be sought.

Detailed findings and conclusions of the studies are presented. Following an introductory section, the subject matter is discussed under the temperature of the ground air zone and factors affecting it, nature of late frost injury to trees and shrubs, occurrence, distribution, and relative severity of the May frosts of 1935, stage of development of trees at the time of the frosts, damage to trees and shrubs, and silvicultural aspects of shelter against frosts. Appendixes take up the late frosts in 1935 and the weather conditions associated with them and the influence of topography on severity of frost. A two-page bibliography is provided.

**1945 weather conditions detrimental to the fruiting of grape vines**, W. K. STEUK (*Ohio Sta. Bimo. Bul.* 240 (1946), pp. 88-91).—A combination of winter-killing, frost, and shelling greatly reduced the 1945 grape crop. Not all varieties were equally susceptible to weather conditions, viniferous hybrids proving more resistant than the labruscan types.

**Researches in dendrochronology**, A. E. DOUGLASS. (*Univ. Ariz.*) (*Utah Univ. Bul., Biol. Ser.*, 10 (1946), No. 1, pp. 19, illus. 17).—The Laboratory of Tree-Ring Research of the University of Arizona has developed a new source of climatic

data in the rings of properly located trees and a new method of cyclic analysis especially adapted to handling climatic changes. These two features seemed to the author to open a gateway through which perhaps long-range forecasting might advance. The purpose of this paper is therefore to give the climatic basis of the tree-ring records studied which make them proper material for studying climate, the extent of these records in time and space, and a survey of the methods and advantages of the cyclic analysis used. The subject matter is discussed under the tree-ring basis of the climatic data, length of the near-climatic records, building a chronology into past climates, geographical areas of the near-climatic records, cyclic analysis of climatic records, and tree rings and forecasting. In conclusion the author states that "perhaps this is one of the first attempts to describe generally the unstable periodicities or cyclics that make up our climatic changes. It is but a beginning, but it may be on the right track. The writer feels that in these cyclics there may be found a real basis for forecasting."

**Tree ring studies in North Dakota**, G. F. WILL (*North Dakota Sta. Bul.* 338 (1946), pp. 24, illus. 7).—Based on a study of the number and width of annual rings shown in cross sections of old logs, timbers, fence posts, and a few old living trees, the author prepared a tree-ring chart covering a long period of years. Correlated with reliable weather records of recent years this chart gave a long-time picture of precipitation in various parts of North Dakota. The longest wet period was 39 yr. and the longest dry period was 16 yr. There appeared to be no definite cycles. Long periods of drought were followed by either long or short wet periods. It appeared that more than half of all the years were wet enough to discourage irrigation, making the area marginal with respect to use of irrigation. Although irrigation facilities would be desirable, they should be of a type that would not carry a large overhead expense in favorable years.

**Insects and weather**—a discussion at a joint meeting of the Royal Entomological Society of London and the Royal Meteorological Society held on 20th June 1945 (*Roy. Met. Soc. [London], Quart. Jour.*, 71 (1945), No. 309-310, pp. 221-230, illus. 3).—The following brief papers—with general discussion—are presented: Phenological Relationships of Meteorology and Entomology, by H. C. Gunton (pp. 221-222); Fluctuations in Insect Populations as Related to Weather Conditions, by C. B. Williams (p. 222); Vertical Air Currents as Agents of Insect Dispersal, by A. E. Slater (pp. 223-226); and The Organisation of Bioclimatic Research, by B. P. Uvarov (pp. 226-228).

**The meteorological control of atmospheric pollution by heavy industry**, E. W. HEWSON (*Roy. Met. Soc. [London], Quart. Jour.*, 71 (1945), No. 309-310, pp. 266-282, illus. 13).—This paper describes a method of reducing atmospheric pollution by varying the emission of offending material with meteorological conditions; the details of application of the technic where the problem was to prevent damage by SO<sub>2</sub> to vegetation are presented. An investigation of the distribution of winds and SO<sub>2</sub> in the Columbia River Valley near Trail, B. C.—where the investigation was made—indicated that during the growing season the majority of the fumigations are brought about by differential heating of the valley sides by the sun. Measured values of atmospheric turbulence and of wind speed and direction are fundamental in the control regime prescribed in this case. The possibility of applying the same principle to other situations, and especially over level country, is discussed.

## SOILS—FERTILIZERS

**Sergei Nikolaevitch Winogradsky, September 1, 1856—August 31, 1946: The story of a great bacteriologist**, S. A. WAKSMAN. (N. J. Expt. Stas.) (*Soil Sci.*, 62 (1946), No. 3, pp. 197-226, illus. 1).—This is a biographical sketch

of this distinguished microbiologist, who died August 31, 1946, on the eve of his ninetieth birthday. A list of about 60 publications is appended.

**Bibliography of soil science, fertilizers, and general agronomy, 1940-44** (*Harpenden, Eng.: Imp. Bur. Soil Sci., 1946, pp 567+*).—This comprehensive volume covers 4 yr. of contributions to soil science. It serves as a cumulative index to *Soils and Fertilizers*, volumes 4 to 7. Material is presented by author and subject matter.

**Environmental factors and their control in plant experiments**, M. W. PARKER. (U. S. D. A.). (*Soil Sci., 62 (1946), No. 1, pp. 109-119, illus. 1*).—The author notes that of the various environmental factors that affect the growth of plants in greenhouses, the light duration or photoperiod and such conditions of the soil as temperature, moisture, aeration, reaction, and nutrients can readily be controlled. The factors of air temperature, humidity, and composition are the most difficult to control because of the constantly and widely changing outside environment, and for control within a narrow range air-conditioning of a greenhouse or construction of controlled-environment rooms is necessary. The construction of chambers has been greatly facilitated by the development of fluorescent-type lamps, and the improvements in air-conditioning equipment have made it possible to condition small greenhouses satisfactorily. If the prevailing climate affords ample sunlight for extended periods, small air-conditioned greenhouses are to be recommended for most experiments, since no artificial source of illumination has been developed that is equivalent to sunlight.

It is emphasized that plant growth is dependent upon all the factors that make up the environment. No particular level of one factor should be referred to as the optimum for growth of a species without specifying at least the approximate levels or conditions of the other important components of the environment. No single optimum for any factor exists that will hold without regard to the status of other factors.

**Pot method for soil cultures**, W. H. MACINTIRE and S. H. WINTERBERG. (Tenn. Expt. Sta.). (*Soil Sci., 62 (1946), No. 1, pp. 33-41, illus. 4*).—The authors discuss equipment (buildings, tables and transfer trucks, and pot cultures) and operative technic (under which are included soil selection and preparation, fertilizing and liming, and growing and harvesting).

**Growing plants in sand cultures for experimental work**, W. R. ROBBINS. (N. J. Expt. Stas.). (*Soil Sci., 62 (1946), No. 1, pp. 3-22, illus. 1*).—"It is not the purpose of this discussion to record all the variations of the sand-culture method, but rather to describe certain equipment and to discuss briefly in comparison with several other technics some of the factors concerned with a technic of continuous solution renewal which has proved satisfactory in this laboratory for the production, in individual sand cultures, of plants excellent in size, productivity, and sensitivity to environmental changes induced by the investigator." To this end, the author discusses the choice of an experimental plant suitable to the conditions and purposes of the experiment; culture equipment, of which the author favors the simpler forms; culture vessels, among which he recommends a pot of high-grade white porcelain with over-all silica glaze, considered to be chemically resistant, strong, a good reflector of sunlight, and free from the tendency to develop the fine cracks through which salts may penetrate and remain as a source of contamination; the sand, which must be white quartz of a high degree of purity for critical work, and should be of closely graded particle size; jars to serve as nutrient-solution reservoirs; nutrient-solution delivery tube; plant, culture vessel, and reservoir supports; waste pan; preparation of equipment for use; preparation of plant material; choice of nutrient solution; preparation of nutrient solutions; application of nutrient solution; and atmospheric conditions.

**Colloidal clay cultures: Preparation of the clay and procedures in its use as a plant growth medium, W. A. ALBRECHT.** (Mo. Expt. Sta.) (*Soil Sci.*, 62 (1946), No. 1, pp. 23-31, illus. 3).—The procedure described is that of the separation from a suitable soil of its finer clay fraction (less than  $0.2\mu$  particle diameter, electrodialysis of this clay, adsorption of known quantities of plant nutrients upon the clay, and the growing of the experimental plants upon mixtures of the prepared clay colloid with quartz sand. Topics considered in the discussion are the separation of the colloidal clay (its source in the soil, its mechanical dispersion, its centrifugal separation); the electrodialysis of the clay (the cathode and its cell, the anode and its cell, continuous operation of the cell, and the rate—from 400 to 500 gm. of colloidal clay in a week of continuous operation of the cell described—of the electrodialyzed product); standardization of the clay suspension; the preparation of the plant-growth media from the clay (calculation of the quantities of the clay and nutrients needed and nitration of the nutrients on the clay); and the accuracy of fertility control permitted by the colloidal clay culture method.

**Modified Mitscherlich method for soil cultures, R. J. BORDEN.** (Hawaii. Sugar Planters' Expt. Sta.). (*Soil Sci.*, 62 (1946) No. 1, pp. 51-60, illus. 1).—The author describes a modified Mitscherlich method (E. S. R., 49, p. 815), used more especially for phosphate and potassium, which has been applied extensively to sugarcane soils in Hawaii. Changes in the original method were chiefly concerned with the indicator crop, the soil dilution, the quantity of phosphate supplied to insure maximum growth, and the use of a specific weight of soil in each pot. The procedure now used is described, and an outline of the treatments used in the complete standard test is given. The method of calculating an "acre-foot soil factor," used in correcting the values found in the Mitscherlich tables, is shown, and an example giving the calculations involved in finding the basic ratios for reference to the Mitscherlich tables is explained. A discussion is included of certain factors that can influence these basic ratios. A table of qualitative groupings for the results from this method of testing soils accompanies a discussion of the manner in which the results are interpreted when recommendations are made for the fertilization of the cane areas from which the soil samples were made.

**Modified Neubauer method for soil cultures, W. T. McGEORGE.** (Univ. Ariz.). (*Soil Sci.*, 62 (1946). No. 1, pp. 61-70, illus. 5).—From a detailed and extended study of the effects of various modifications of the original procedure, the author concludes that with modifications to suit laboratory or greenhouse temperatures, preferably not over 22° C., the Neubauer method (E. S. R. 53, p. 319) offers a procedure for the examination of the fertility of the soil in which the plant is used as an indicator. Most important is the observation that at this temperature the Neubauer method can be further modified to the extent that the method becomes an important research tool for the study of plant nutrition and especially the growth-limiting factors that are always present in greater or less degree in semiarid soils.

Like chemical soil analysis, the Neubauer method is an empirical method, and therefore adherence to the 100 : 100 ratio of weight of soil to number of seedlings is essential for obtaining Neubauer values. As a research tool in the study of soil and nutritional problems, it is advisable to vary this ratio or absolute weight of soil and number of seedlings in order to get a broader knowledge of the inherent soil conditions being studied. With the same technic, many seedlings other than rye can be grown on a quantitative basis where one desires to study the growth-limiting factors for other seedlings.

A modification of the method which has given entirely satisfactory results at the Arizona Experiment Section for more than 10 yr. is given in working detail.

**Large-scale soilless culture for plant research**, O. W. DAVIDSON. (N. J. Expt. Stas.). (*Soil Sci.*, 62 (1946), No. 1, pp. 71-86, *illus.* 4).—From extensive experience of the method, the author finds that the use of large artificial cultures in plant research offers a degree of control over inorganic nutrition not attainable with soil. It also permits economy of time in growing large numbers of plants as well as large quantities of plant material. The choice of one method of artificial culture over another should depend upon the requirements of the individual investigation. Thus, solution cultures offer the highest degree of control over the composition of the nutrient substrate. They also permit convenient access to roots, as for sampling and making observations. Sand cultures permit greater ease of growing and supporting plants than do solution cultures, but at some sacrifice in refinement of nutrient control. Gravel culture offers about the same degree of control over the composition of the substrate as does the sand method. Depending upon the frequency of the pumping or flooding cycle, the changes occurring in nutrient concentration about the plant roots may be even less than in sand. Gravel cultures furnish the most favorable conditions of root aeration with a minimum of attention.

**Arrangement of soil series and types according to functions of soil-forming factors**, H. JENNY. (Univ. Calif.) (*Soil Sci.*, 61 (1946), No. 5, pp. 375-391, *illus.* 9).—On the basis of a generalized equation relating soil-forming factors, five groups of pedologic functions are recognized. Criteria for evaluating in a given area the dominant and subdominant soil-forming factors are stated. Soil series and types are arranged in five sequences: Chronosequences, lithosequences, toposequences, climosequences, and biosequences. The relationships of these sequences to Bushnell's multiple catenas (E. S. R., 91, p. 644) and Thorp's families (E. S. R., 88, p. 163) are brought out. The genetic classification of soil series is held to constitute a 5-dimensional network of series, each being linked, in principle, to 10 other series.

**A pedologic study of California Prairie soils**, I. BARSHAD. (Univ. Calif.) (*Soil Sci.*, 61 (1946), No. 6, pp. 423-442, *illus.* 5).—It is shown that the California Prairie soils and the midwestern Prairie soils are very similar in many soil properties, although the soil-forming factors are not identical. The similarity of the soils suggests that certain properties of the soil-forming factors of the two geographic regions must be alike, and dominant in determining certain soil properties. An evaluation of the soil-forming factors of the two regions led to the conclusion that the dominant properties among the soil-forming factors for the prairies investigated are (1) climate, classified for both regions as sub-humid; (2) organisms, a dense ground cover of either grass or shrubs; (3) topography, upland with good drainage conditions; (4) time or age, fairly advanced (a considerable range for the midwestern Prairies); (5) parent material, the one dominant property is the relatively high calcium and magnesium content (4.4 to 13.1 percent).

**Relation of parent material and environment to the clay minerals in Iowa soils**, J. B. PETERSON. (Iowa Expt. Sta.) (*Soil Sci.*, 61 (1946), No. 6, pp. 465-475, *illus.* 5).—From differential thermal analysis, X-ray diffraction pictures, and analysis of base-exchange capacity, it was found that Iowa soils with parent material of Pleistocene origin, which includes most of the soils of the State, are characteristically high in montmorillonite. The proportion of montmorillonite to kaolinite in these profiles was found, however, to vary according to climate, vegetation, and source and age of the parent material. The profiles studied indi-

cate that there is little difference between the A and B horizons of either Prairie or Wiesenboden soils of the Wisconsin drift in respect to the kinds and amount of clay minerals in the clays. Generally in soils on older Pleistocene materials the proportion of montmorillonite to kaolinite was lower in the A and higher in the B, this shift being greater in the Gray-Brown Podzols and Planosols than in the Prairie soils. There was also evidence that the increase in montmorillonite in the clay of the B horizon was greater in areas of greater rainfall.

**Some properties of Wasatch Mountain Soils,** A. R. CROFT and J. P. THORNE. (U. S. D. A.) (*Utah Acad. Sci. Arts. and Letters, Proc.*, 21 (1943-44), p. 6).—The authors point out some relations of such soil properties as texture, organic matter content, and reaction or pH, with site factors such as aspect of slope, elevation, plant type, and degree of accelerated erosion. Composite soil samples were taken at two depths (0-1 and 1-6 in.) on six minor watersheds tributary to Farmington Creek. Soils to a depth of 6 in. were found to be coarse textured, relatively high in organic matter, and definitely acidic. Differences in soil properties on the north, east, and west aspects were small. Decreasing percentages of silt and organic matter and decreasing pH were found to be associated with increasing elevation. Browse species appeared to favor a less acid soil and a better incorporation of organic matter into the soil than did aspen-fir cover. Within browse and aspen-fir areas pH values were found to be almost normally distributed. Soils in the severely eroded areas were coarser in texture and contained but one-half as much organic matter as did those in the noneroded areas.

**Seasonal variability in the aggregation of Hagerstown silt loam,** R. B. ALDERFER. (Pa. Except. Sta. coop. U. S. D. A.). (*Soil Sci.*, 62 (1946), No. 2, pp. 151-168, *illus.* 2).—Soil structure, measured by the percentage of the soil aggregated into particles  $>0.25$  mm. in diameter on the basis of  $105^{\circ}$  C. oven-dry weight, was subject to wide seasonal variations. In its field-moist condition, the soil had a minimum percentage of water-stable aggregates during the hot, dry period (July and August) and maxima in November and in February. Soil moisture content was closely related to the percentage and size of water-stable aggregates when the soil was analyzed in its field-moist condition. The effect of soil moisture content was modified, however, by such seasonal conditions as alternate wetting and drying during the summer and by alternate freezing and thawing. These influences effected a large but temporary increase in aggregation during the late winter. Laboratory air-drying effected a marked change in the size and quantity of water-stable aggregates as compared with the aggregate distribution in the soil at its actual field moisture content. In the air-dry condition the soil had a maximum percentage of water-stable aggregates during July, August, and September and a minimum during the winter and early spring months. Aggregation varied markedly in the several layers of surface soil under different treatments. Aggregation was greatest in the 1-3-in. surface layer of the tilled soils in which various materials were incorporated, whereas the 0-1-in. layer possessed the least quantity of the larger aggregates. Aggregation of the 3-6-in. surface layer was generally slightly less than that of the 1-3-in. layer. The 0-1-in. layer was somewhat less aggregated, and the 3-6-in. layer remained almost wholly unaffected by the presence of the surface mulch.

**Physical land conditions in Anderson County, South Carolina,** E. A. BURGESS ET AL. (U. S. Dept. Agr., Soil Conserv. Serv., *Phys. Land Survey No. 38* (1946), pp. 46+, *illus.* 17).

**Observations on alkali soils in Iran,** D. W. PITTMAN. (Utah State Agr. Col.) (*Utah Acad. Sci., Arts, and Letters, Proc.*, 21 (1943-44), pp. 97-99).—The author found that in Iran, as in most desert countries, one of the chief soil problems is alkali. The valley soils are predominantly of the gray desert type and in

many places are so rich in salt that after 1 or 2 yr. of irrigation the lands becomes worthless. Some rather extensive development projects have failed for this reason. Several instances of this sort are described. The "alkali" found was nearly always salinity only, the soil reaction being rarely more alkaline than pH 8.5. The saline material consisted mostly of a mixture of sodium sulfate and chloride in the ratio of about 3 to 1. At one point, however, the author found a soil containing such an excess of nitrates as to give off abundant fumes of nitrogen peroxide when heated with acid to determine its content of organic matter. The native reclamation method was found to be that of flooding and then permitting the water to run off, with or without the growing of a rice crop during the period of flooding. An instance of the very successful use of this method, in conjunction with surface drains, is described.

**Early investigations dealing with water runoff and soil erosion, M. F. MILLER.** (Univ. Mo.). (*Jour. Amer. Soc. Agron.*, 38 (1946) No. 7, pp. 657-660, illus. 2).—This historical note concerns preliminary work already reported upon in 1928 (E. S. R., 51, p. 210) and in 1932 (E. S. R., 69, p. 118).

**Displacement of soil-air by CO<sub>2</sub> for permeability tests, J. E. CHRISTIANSEN, M. FIREMAN, and L. E. ALLISON.** (U. S. D. A. et al.) (*Soil Sci.*, 61 (1946), No. 5, pp. 355-360, illus. 2).—The experiment reported herein indicates that the air which is normally entrapped within a soil upon wetting can be eliminated by displacing it with the much more soluble gas, carbon dioxide, prior to wetting. When this is done, the permeability is at a maximum at the beginning of the test or shortly thereafter. Where it is desirable to determine the permeability rates for complete saturation, this technic eliminates the necessity of long-time tests. For subsoils, sands, and structureless materials, in which the decrease in permeability is very gradual, the initial permeabilities of the CO<sub>2</sub>-treated samples were found approximately the same as the maximum permeabilities for the untreated samples, which are obtained only after a period of a few to many days. In surface soils, however, the initial rates for the CO<sub>2</sub>-treated samples were appreciably higher than the maximum rates reached by the untreated samples. The technic described here is believed to have special time-saving value in connection with permeability tests for drainage studies and other engineering purposes where the permeability of completely saturated materials is desired.

**Relation of moisture tension to heat transfer and electrical resistance in plaster of paris blocks, H. R. HAISE and O. J. KELLEY.** (U. S. D. A.) (*Soil Sci.*, 61 (1946), No. 5, pp. 411-422, illus. 8).—Calibration curves relating moisture tension to electrical resistance and heat transfer in gypsum plaster blocks of the type designed by Bouyoucos and Mick (E. S. R., 83, p. 307) for the measurement of soil moisture percentage are presented. The errors and difficulties encountered in making these calibration curves by means of a pressure-membrane technic are discussed. A desorption curve determined for gypsum plaster indicated that most of the moisture is held at tensions below 4 atmospheres.

**The influence [of] incubation temperature on the microbiological activities in some soils, L. W. JONES and J. E. GREAVES.** (Utah State Agr. Col.) (*Utah Acad. Sci., Arts, and Letters, Proc.*, 21 (1943-44), pp. 75-78).—Soils incubated at varying temperatures in the determination of numbers, ammonifying, nitrifying, and nitrogen-fixing powers showed different optimum temperatures. In all but one soil the optimum temperature for the maximum bacterial counts was 30° C. In the one exceptional soil this optimum temperature occurred at 20°. The optimum temperature for ammonia accumulation was between 40° and 50°. The optimum for nitrate accumulation varied. In some soils it was 20° and in others it was 30°. In all soils it was lower than for optimum ammonia accumulation. Nitrogen fixation proceeded at a measurable rate at 10° and became quite

active at 20°. It reached its maximum at 30°. Nitrification was often stopped at 40°. Nitrogen fixation was seldom stopped at this temperature, and ammonification never in the soils tested.

**Alfalfa decreases in the Black Belt with decreases in soil fertility,** H. B. VANDERFORD (*Miss. Farm Res. [Mississippi Sta.], 9 (1946), No. 3, p. 2*).—The failure of alfalfa to grow on soils where it had been grown successfully for years in the Black Belt section of Mississippi was found to be closely associated with a decline in soil fertility. Results from an experiment started in 1926 indicated that manure and phosphate supplied the needed elements. In recent years it has been found that boron and potash are also necessary for efficient alfalfa production on some soils.

**Effects of organic residues and nitrogen fertilizers on a semiarid soil,** V. T. SMITH, L. C. WHEATING, and S. C. VANDECAVEYE. (Wash. Expt. Sta.) (*Soil Sci., 61 (1946), No. 5, pp. 393-410, illus. 3*).—Conditions and methods having been outlined under the heads of climate, soil and plot arrangement, and harvesting, sampling, and analysis methods, the authors give their results as grain yields, nitrogen content of the wheat, yields and nitrogen contents of the straw, available soil moisture, soil nitrate-nitrogen content, and changes in the organic carbon and in the nitrogen content of the soil.

During the treatment period (1922-40), the soil treatments described produce no marked increase or decrease in the yield or bushel weight of wheat. The nitrogen content of the wheat was increased by the manure treatment, by treatments of ammonium sulfate alone, and by treatments of straw with ammonium sulfate. Grain from the plots receiving ammonium sulfate alone had the highest nitrogen content, followed in descending order by the grain from treatments of 100 lb. ammonium sulfate with 1,600 lb. straw, 50 lb. ammonium sulfate with 800 lb. straw per acre, and of manure alone. The yields of straw were greatest on the plot receiving 100 lb. of ammonium sulfate with 1,600 lb. of straw per acre, followed in order by the treatments of 50 lb. of ammonium sulfate with 800 lb. of straw, 3,200 lb. of straw alone, 100 lb. of ammonium sulfate alone, 7,000 lb. of manure, 50 lb. of ammonium sulfate alone, 1,600 lb. of straw alone, and 800 lb. of straw alone. Numerous like data are discussed, summarized, and tabulated.

**Effect of different sources of nitrogen on soil reaction, exchangeable ions, and yields of crops,** N. J. VOLK and J. W. TIDMORE. (Ala. Expt. Sta.) (*Soil Sci., 61 (1946), No. 6, pp. 477-492*).—Fertility plots established in Alabama in the period 1928 to 1930 were studied to determine the long-time effect of various sources of nitrogen on the chemical composition of several soils and on the yields of seed cotton and corn. Samples of soils taken from the plots of the nine different sites in 1941 were analyzed for soil reaction and for exchangeable hydrogen, calcium, magnesium, and potassium.

On most sites, the nonacid-forming sources of nitrogen, except cyanimid, were definitely superior to the acid-forming sources for the production of cotton and corn when acidity was not corrected, producing an average of about 100 lb. of seed cotton and 3 bu. of corn more per acre. When the acidity of the acid-forming fertilizers was corrected, however, these differences were eliminated at most sites. Results at most sites were inferior with calcium cyanamid. A mixture consisting of three-fifths to three-fourths of the nitrogen as sodium nitrate and two-fifths to one-fourth as ammonium sulfate gave the greatest average returns of seed cotton. Sodium and sulfur may have been responsible for the increase, but the difference in returns between this mixture and some other sources of nitrogen were not great. When dolomite was added to acid-forming fertilizers, the average yield of seed cotton was increased 143 lb. per

acre and of corn 3.8 bu. per acre over an 11- to 13-yr. period, and, when added to nonacid-forming fertilizers, the average yield of seed cotton was increased 83 lb. per acre and of corn 2.3 bu. Part of the increase is held undoubtedly to have been due to the magnesium in the dolomite. Numerous further observations and conclusions of a like nature are detailed.

**Chemical relationships of potassium and magnesium in organic and sandy soils of central Florida, V. C. JAMISON.** (Fla. Expt. Sta.) (*Soil Sci.*, 61 (1946), No. 6, pp. 443-453, illus. 2).—This paper is concerned with sandy ridge soils, light, of poor fertility, and of very low exchange capacity (about 2 milliequivalents per 100 gm. in the surface, and about 1 m. e. in the subsoils), used for citrus plantings because they are less susceptible to cold injury than are surrounding areas of lower level. Of its low exchange capacity, Norfolk fine sand, for example, lost more than four-fifths on removal of its organic matter by oxidation. It was found that although the pH is a factor in the retention of potassium in light sandy and organic soils of Florida, potassium retention in these soils is so weak as to make pH of little practical consequence. On the other hand, magnesium was more strongly adsorbed, and the pH of the soil and the presence of unreacted lime residues were of great significance in magnesium conservation. Practically no fixation of potassium in nonexchangeable form was observed. Potassium accumulated from applications only temporarily when there were droughty periods. When the rains came again, that which had accumulated was leached.

**The comparative effects of lime and gypsum upon plants grown on acid soils, M. FRIED and M. PEECH.** (Cornell Univ.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 614-623).—Barley, perennial ryegrass, and alfalfa were used as the test crops. The plants grown on limed soils absorbed much more calcium and gave much higher yields than those grown on gypsum-treated soils despite the higher concentration of calcium in soil solution in the gypsum-treated soils. For some reason not yet determined, the plants were unable to absorb calcium from the acid soil even when supplied with an adequate quantity of soluble calcium salt. There was good indication that manganese, which was absorbed readily by all plants, may have prevented the uptake of calcium. For example, an application of 200 lb. of manganese, as  $MnCO_3$ , per 2,000,000 lb. of soil to an acid soil virtually prevented the growth of alfalfa. It is pointed out that this quantity of manganese is not much in excess of the quantities usually found in acid soils in exchangeable and water-soluble forms. Liming reduced the manganese content of all the three crops investigated and decreased the aluminum content of alfalfa. An application of 50 lb. of iron, as  $FeSO_4$ , per 2,000,000 lb. of soil appreciably reduced the yield of perennial ryegrass without affecting the iron content of the plants. The quantities of iron and phosphorus in the plants were relatively unaffected by any of the treatments. It is noted that these results indicate that the poor growth of plants on acid soils is not necessarily due to the lack of an adequate supply of calcium, but that the response of crops to lime on acid soils is quite complex, involving several contributing factors such as toxicity of manganese, iron, and aluminum, the relative significance of which probably varies with different crops and soils.

**Absorption of calcium by peanuts from kaolin and bentonite at varying levels of calcium, A. MEHLICH and W. E. COLWELL.** (N. C. Expt. Sta.) (*Soil Sci.*, 61 (1946), No. 5, pp. 369-374, illus. 2).—Relatively pure colloidal material of the 1:1 and 2:1 lattice types was used. Variations in adsorption capacity were provided by dilutions with quartz sand.

From all systems the uptake of calcium increased with increasing calcium levels. The calcium contents of peanut shells produced in the kaolinitic systems

were higher than those grown in the bentonite media. This difference was more pronounced at high percentages of calcium saturation and at the higher cation adsorption capacity levels (2.4 milliequivalents per 100 gm.). Uptake of calcium from the kaolinitic systems was more directly related to total calcium than to degree of saturation. In the montmorillonitic systems, absorption was more directly related to percentage calcium saturation. In the kaolinitic type of colloid, peanuts of good quality were obtained even at relatively low calcium levels. In the bentonitic system more calcium at high degrees of saturation was required for this.

**Some relations between ferrous and ferric iron and high-line chlorosis,** D. W. THORNE and A. WALLACE. (Utah Expt. Sta.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 21 (1943-44), p. 5).—The work here abstracted indicated that the ferrous is the more active form of iron in calcareous soils and in plants and that a deficiency of it is closely related to chlorosis. Soils deficient in available iron contained less iron that can be readily reduced to the ferrous form than did soils producing green plants. Chlorotic leaf tissues contained less soluble ferrous iron and had less capacity to reduce ferric iron to the ferrous form than did green leaf tissues. As a result of this study it is suggested that the oxidation-reduction potential of soils and plant tissues deserves more attention in relation to high-lime chlorosis than has been previously given it.

**Possible role of boron in tobacco fertilization,** T. R. SWANBACK. (Conn. [New Haven] Expt. Sta.). (*Soil Sci.*, 62 (1946), No. 2, pp. 137-149).—The author made a study of growth, quality, and some of the chemical constituents of Havana Seed tobacco grown in the Connecticut Valley under various fertilizer treatments on selected fields, 1941 through 1944, the results leading to the following conclusions:

Brown root rot in tobacco may be due to "crop fatigue" caused by insufficient boron or improper balance of potassium, calcium, and boron in the soil. Tobacco can be grown successfully after corn provided the level of soil fertility of corn land is on a par with that of tobacco land in good production, including sufficient boron. Suitable quantities of borax applied to corn land and tobacco land improved crop values as much as 12 percent. Potassium-calcium ratios, based on crop analyses, are widened by applied borax, that is, potassium increases in the plant while calcium remains fairly constant. A sufficient quantity of boron added to limed land will maintain a proper potassium-calcium balance. Satisfactory yields are obtained when the calcium-boron ratio in the crop is about 900 to 1. For considerable improvement in an already satisfactory crop, the ratio must be narrowed to about 300 to 1. Because of the close interrelation of potassium-calcium-boron, a ratio expressed by the fraction  $(K \times B / Ca)$  is suggested. This ratio widens as the crop values increase. On typical Connecticut Valley tobacco soil the plants can tolerate more than 4 p. p. m. of boron but less than 8 p. p. m., and it would be safer not to exceed the lower figure. The ration of replaceable calcium to boron in soils is reflected to some degree in the corresponding ratio of the crop. The common practice of fertilization of tobacco in the Connecticut Valley maintains the boron status in the soil, partly by small additions of boron in the fertilizers and partly through the reactions in soil constituents of the materials added. Recommendations as to a general use of borax on tobacco land must await further investigation.

**Fluorine in soils,** W. O. ROBINSON and G. EDGINGTON. (U. S. D. A.) (*Soil Sci.*, 61 (1946), No. 5, pp. 341-353).—The authors determined the fluorine contents of 137 samples taken at various depths from 29 profiles representing the continental United States from New Hampshire to Texas and from Washington to Florida and from the Oahu clay profile of Hawaii. The samples cover a

variety of textures and parent materials. The average value found for the fluorine content of the surface soils was 292 p. p. m., but one of the four layers in a Michigan loamy sand showed only a trace and a Tennessee soil containing phosphate rock was found to contain 7,070 p. p. m. of fluorine in the layer at from 25 to 40 in. depth. In general, the fluorine content increased with the depth of the soil. Fluorine was considerably concentrated in the colloidal matter. Much of the fluorine in soils highest in fluorine was in the form of apatite. In general, the main source of fluorine in the ordinary soil consisted of the micaceous clays and there was no correlation between the phosphorus and fluorine contents of soil where the fluorine present was not mainly in the form of apatite. Six samples of micaceous clays which probably occur in soil had fluorine contents ranging from 300 to 7,400 p. p. m., averaging 3,730 p. p. m. An Ordovician bentonite contained the maximum quantity of fluorine. Much of the fluorine added to the soil in the form of superphosphate was found to be retained by the heavier textured soils, while coarse sandy soils retained less. Added fluorine in the form of superphosphate did not appear to increase significantly the fluorine content of plants. The fluorine contents of 28 samples of vegetation grown on a soil of known fluorine content are given.

**Occurrence of selenium in Pleistocene deposits and their derivatives in South Dakota.** W. V. SEARIGHT, A. L. MOXON, R. J. HILMOE, and E. I. WHITEHEAD. (S. Dak. Expt. Sta.). (*Soil Sci.*, 61 (1946), No. 6, pp. 455-468, illus. 1).—The authors investigated Pleistocene deposits, soils, plants, and bedrock materials in relation to selenium content and the source of selenium. The area studied included all of 10 counties and parts of 6 other counties in northeastern South Dakota. Selenium determinations were made on 220 composited samples of 15 glacial and related deposits and on samples representing 22 ft. of bedrock.

None of the till samples were selenium-free. Local maxima reach 3.70, 4.92, 5.38, and 0.86 p. p. m. selenium for undifferentiated Kansan and Iowan, Arlington, DeSmet, and Mankato tills, respectively. On the average, the tills contained less than 1.5 p. p. m. selenium. Arlington loess and loesslike silts contained little selenium in upland and hilltop positions, but depressions contained noteworthy quantities. Soils formed on loess and loesslike silts, particularly at low topographic positions, appeared to be more seleniferous than parent materials. The average selenium content of the soils analyzed was nearly 91 percent greater than the average selenium content of the loesslike silts. Outwash and valley train deposits contained selenium in varying quantities up to 3.72 p. p. m. Several cattle on one farm showed pronounced symptoms of chronic selenium poisoning in the winter of 1944-45. Considerable yearly variation was found in the selenium content of *Astragalus racemosus* Pursh samples grown in the area. All samples containing over 1,000 p. p. m. selenium were found growing in poorly drained, low topographic positions; pond water and ground water at these locations contained appreciable amounts of selenium in solution. The probable sources of the selenium in the Pleistocene deposits and soils developed thereon are discussed.

**Some results from applications of coal to Utah soils.** J. P. and D. W. THORNE. (Utah Expt. Sta.). (*Utah Acad. Sci., Arts. and Letters, Proc.*, 21 (1943-44), pp. 79-86, illus. 1).—Some commercial interests and a few investigators have recently advocated the use of coal or related materials for fertilizer. On the other hand, farmers in one of the coal mining areas of Utah have claimed damage to crops from deposits of slaked coal left on cropland by irrigation water.

During a 12-week nitrification test, coal, roasted coal, and peat produced no nitrate nitrogen, while three commercial coal fertilizers and the standard low-grade fertilizer did produce some quantities of nitrate. The standard fertilizer

was, however, the only one of the above materials which increased the yield of corn plants. Neither the coal itself nor the commercial so-called growth hormone extracted from coal was found to be of any appreciable value as fertilizer. The effects of coal at a rate of 5 tons or more per acre were found to be essentially the same as the effect of like quantities of sand added. In some instances increased yields were obtained, but additions of sand also increased yields and this effect probably resulted from improved physical conditions in the pots. Slaked coal applied to the surface of soils to a depth of 2 in. was not injurious to the growth of tomatoes under greenhouse conditions, but mulches were found generally beneficial in the greenhouse. No evidence to indicate that soil treatment with coal has any practical value in improving plant growth was found.

**Fertilizer use and crop yields:** A list of references, J. M. McNEILL (*U. S. Dept. Agr., Libr. List* 27 (1946), pp. 67).—This bibliography lists publications from the United States and territories containing original experimental data on the effects of fertilizer use on crop yields. It covers the period 1925-45, with a few items published in 1946.

**Inspection of commercial fertilizers and agricultural lime products for the season of 1945,** P. H. SMITH ET AL. (*Massachusetts Sta. Control Ser. Bul.* 126 (1945), pp. 28).—In addition to the usual analytical data for fertilizer mixtures and substances supplying single elements, the approximate money value of the shortage in plant food content per ton is added to the tabulation of the small number of deficient brands. Discovery of a substantial adulteration of bone meal with phosphate rock and ammonium sulfate or urea or both is reported upon.

## AGRICULTURAL BOTANY

**Synthesis of a polysaccharide from sucrose by *Streptococcus* s. b. e.,** C. F. NIVEN, JR., Z. KIZICTA, and J. C. WHITE. (Cornell Univ.). (*Jour. Bact.*, 51 (1946), No. 6, pp. 711-716).—Of the 34 strains of *Streptococcus* s. b. e. recovered from cases of subacute bacterial endocarditis, 32 synthesized large quantities of a polysaccharide from sucrose in broth culture, but synthesized little or none when streaked on sucrose agar. This unique property may prove helpful in identifying this streptococcus, such cultures having been recovered from about a third of the cases studied. The polysaccharide has been tentatively identified as a dextran.

***Streptococcus* s. b. e.: A streptococcus associated with subacute bacterial endocarditis,** J. C. WHITE and C. F. NIVEN, JR. (Cornell Univ.) (*Jour. Bact.*, 51 (1946), No. 6, pp. 717-722).—The authors describe a hitherto unrecognized group of streptococci associated with subacute bacterial endocarditis; the streptococcus is of the viridans type, having a unique combination of physiological characteristics, including the ability to synthesize large amounts of a polysaccharide in a sucrose broth, to hydrolyze arginine, and to ferment inulin but not raffinose. The species name *S. sanguis* seems appropriate.

***Streptococcus* s. b. e.—immunological characteristics,** M. R. WASHBURN, J. C. WHITE, and C. F. NIVEN, JR. (Cornell Univ.). (*Jour. Bact.*, 51 (1946), No. 6, pp. 723-729).—The 42 cultures of *Streptococcus* s. b. e. recovered from subacute bacterial endocarditis fell into two serological types as determined by the precipitin technic. Five cultures gave positive precipitin tests with both type I and type II antisera. A serum prepared against one of these strains reacted with all 42 cultures; this appears to be due to the presence of antigens of both types in the cells of these strains. There appears to be a number of agglutinating antigens in the individual strains; the agglutination test, however, is not suitable for identifying this organism.

**A study of streptococci associated with subacute bacterial endocarditis,** C. F. NIVEN, JR., and J. C. WHITE. (Cornell Univ.). (*Jour. Bact.*, 51 (1946), No. 6, p. 790).—A collection of 113 cultures of streptococci isolated from 100 cases of subacute bacterial endocarditis was studied in an attempt to classify them according to their physiological and serological characteristics; the results are tabulated.

**The influence of changes in concentration of sodium hydroxide upon its bactericidal activity,** F. W. TILLEY. (U. S. D. A.) (*Jour. Bact.*, 51 (1946), No. 6, pp. 779-785, illus. 3).—The bactericidal efficiency of sodium hydroxide against *Staphylococcus aureus* and *Escherichia coli* was determined by a modified Rideal-Walker technic. From the resulting experimental data, values for the concentration exponent  $n$  were calculated by the formula previously described, viz.  $n = \log t_2 - \log t_1 / \log C_1 - \log C_2$  for results presented in tabular form and by the formula  $n = y_2 - y_1 / x_1 - x_2$  for those presented in graphical form. When test cultures were grown in ordinary beef infusion broth, the values obtained for  $n$  were approximately 1.6 for *S. aureus* and 5.6 for *E. coli*. Within a comparatively limited range of concentrations the bactericidal action of sodium hydroxide against both test organisms followed, with either small or large amounts of organic matter, an approximately logarithmic course. However, the slope of the curve was related to the organic matter present. Bactericidal efficiency was correlated with the final pH of the test mixtures. When the pH fell below 10, efficiency suddenly dropped and at a pH between 10 and 9 disappeared altogether.

**Metabolism and the chemical nature of *Streptomyces griseus*,** S. A. WAKSMAN, A. SCHATZ, and H. C. REILLY. (N. J. Expt. Stat.). (*Jour. Bact.*, 51 (1946), No. 6, pp. 753-759).—Growth of *S. griseus* was found to reach a maximum in stationary cultures in 10 days and in submerged cultures in 3 to 5 days, followed by lysis of the mycelium; it was accompanied by a gradual rise in the pH value of the culture and in the  $\text{NH}_3$  and amino-N contents. The total N in the mycelium tended to be higher during active growth stages. Production and accumulation of streptomycin paralleled the growth of the organism. After maximum activity was reached, there was a drop in activity—rapid in submerged cultures. For streptomycin production, the presence in the medium of an organic substance is required. This substance may be designated as an "activity factor," either serving as the precursor of the streptomycin molecule as a whole or of an important group in the molecule, or functioning as a prosthetic group in the mechanism essential for its synthesis. Such a factor can be gradually synthesized by the organism; when it is provided in the medium in a preformed state, however, as in meat extract or in corn steep, the process of streptomycin synthesis is greatly facilitated. *S. griseus* produces another antibiotic which is present in limited amount in the culture filtrate but more abundantly in the mycelium; it is distinct from streptomycin, being soluble in organic solvents and inactive against gram-negative bacteria.

**The production of penicillin X in submerged culture,** K. B. RAPER and D. I. FENNELL. (U. S. D. A.) (*Jour. Bact.*, 51 (1946), No. 6, pp. 761-777, illus. 4).—Of several good penicillin-producing strains investigated, *Penicillium chrysogenum* NRRL 1984.A—a substrain derived from Minn. R-13—proved the best producer of chloroform-insoluble penicillin (penicillin X) when grown in submerged culture. By ultraviolet irradiation, a substrain designated NRRL 1984.N22 was developed; it produced substantially higher yields of penicillin X. The superior performance of the new substrain as a producer of penicillin X was repeatedly observed in shaken-flask cultures and was subsequently demonstrated in 600-l. vat fermentations. From one of these fermentations pure penicillin X

was isolated in a quantity verifying the approximate correctness of the survey data based on differential assays only. The technic of irradiation, the method of performing chloroform extractions, and the theory and practice of the differential assay used in demonstrating the presence and determining the amount of penicillin X are presented.

**A comparison of penicillin-producing strains of *Penicillium notatum-chrysogenum*, F. B. GAILEY, J. J. STEFANIAK, B. H. OLSON, and M. J. JOHNSON.** (Wis. Expt. Sta. et al.). (*Jour. Bact.*, 52 (1946), No. 1, pp. 129-140, illus. 1).—The penicillin-producing properties and gross metabolic characteristics of a number of strains of the *P. notatum-chrysogenum* group were compared in 100-gallon-tank fermentations. Aside from adequate aeration, the conditions apparently necessary for optimum penicillin production are rapid initial production of mycelium, the presence of a slowly fermentable carbohydrate and available N (e. g.,  $\text{NH}_3$ ) and maintenance of pH values at 7.0 to 7.8. The yield under these conditions varied widely with the culture used. Of the many strains tested, the mutant *P. chrysogenum* strains X-1612 and Q176 produced the highest yields; strain X-1612 yielded 400 to 500 units per cubic centimeter, and strain Q176 gave 700 to 900 units per cubic centimeter.

**The effect of environmental conditions on penicillin fermentations with *Penicillium chrysogenum* X-16-12, J. J. STEFANIAK, F. B. GAILEY, F. G. JARVIS, and M. J. JOHNSON.** (Wis. Expt. Sta. et al.). (*Jour. Bact.*, 52 (1946), No. 1, pp. 119-127, illus. 5).—Penicillin yields were not appreciably affected by incubation temperatures of 20° to 29° C., but at 32° yields were definitely lower; metabolic processes were more rapid at higher temperatures. Fermentations were usually conducted at a tank pressure of 20 lb. per square inch; reducing this to 2 lb. failed to affect the fermentation, but at a tank pressure of 40 lb. per square inch the penicillin yields were reduced. Increased  $\text{CO}_2$  tension did not affect penicillin fermentations. The metabolic changes in fermentations where glucose was the carbohydrate source were compared with those on standard lactose medium. Toxicity tests of antifoam agents in shake-flask experiments were performed. Of the agents proving nontoxic, 3 percent octadecanol dissolved in lard oil was found to be the best agent for controlling foam in tanks.

***Najas arguta* in Central America and its relationship to *N. wrightiana*, R. T. CLAUSEN.** (Cornell Univ.). (*Bul. Torrey Bot. Club*, 73 (1946), No. 4 pp. 363-365, illus. 1).—A taxonomic study of these members of the pondweed family, with two new subspecies of *N. wrightiana*.

**The perennial species of *Urtica* in the United States east of the Rocky Mountains, F. J. HERMANN.** (U. S. D. A.) (*Amer. Midland Nat.*, 35 (1946), No. 3, pp. 773-778).—In connection with the growing economic interest in the nettle as a source of chlorophyll, a review of the United States species of the genus was undertaken as a preliminary step in making field trials of such kinds as might be brought under cultivation in the eastern part of the country. Studies of the perennial nettles of eastern North America in the herbarium and under cultivation suggest that there is but one species, *U. dioica*; the typical form of this plant may have been introduced from Europe, although the evidence in hand fails to warrant a conclusion one way or the other. The nomenclatorial status of variants of *U. dioica* are discussed.

**The edaphic factor in narrow endemism.—I, The nature of environmental influences, H. L. MASON.** (Univ. Calif.) (*Madroño*, 8 (1946), No. 7, pp. 209-226).—The dynamics of the geographic distribution of any species involves the interactions between the environment, the physiological processes of the individuals of a population, and the genetic processes that fix tolerances and maintain or elaborate the population and preadapt individuals to environal fluctuations.

Endemic species do not differ significantly from so-called "ordinary" species in their dynamics; restriction in geographic range as applied to endemic species is thus of the same order—insofar as cause and effect are concerned—as the restriction of any and all other species. The area occupied by any species is determined by factors whose various conditions occupy an area independently of the fact that species might be restricted by them. Since only environmental conditions independently occupy an area, it is the environment that determines the pattern of distribution of all plant species by permitting the functioning of only those individuals whose tolerances have been preadapted to the special conditions of the environment. Of the various categories of environmental factors, the condition of any factor or combination of factors may serve to restrict the range of some plant species. Of these factors, however, the edaphic factor is most apt to occur in sharply defined patterns and often in small areas. In this connection, the regular occurrence—the world over—of highly restricted species in association with certain minerals and metals in the soil solution suggests that these substances play an important role in problems of the geographic distribution of highly restricted species. There are 16 references.

**Variation in seed as shown by symbiosis, J. K. WILSON** ([*New York*] *Cornell Sta. Mem.* 272 (1946), pp. 21, illus. 5).—The author studied variations in seeds from individual plants of four species (red and alsike clovers, black locust, and *Sesbania exaltata*). The comparative variation in each collection was ascertained by exposing plantlets to certain isolates of legume bacteria, the criterion being the nodulated condition of 30-day-old seedlings. The seeds were etched with concentrated  $H_2SO_4$ , washed in water, bathed in a filtered solution of calcium hypochlorite, and planted, with the chlorine adhering to them, in previously sterilized flasks containing soil. Seedlings of each collection were exposed to the diverse isolates by dropping a suspension of the culture on the surface of the soil in the flasks. Controls were provided.

The results indicated that plantlets grown from seeds of an individual plant of the species employed may symbiose with a certain isolate, whereas plantlets grown from seeds of another plant of the same species may bear no nodules after exposure to the same isolate. This may be taken as evidence that seeds from cross-pollinating individual plants possess unlike generic characters as related to nodulation. Such variations are not embraced in the Linnaean concept of a species. The data also indicate that isolates representing several of the proposed cross-inoculation groups are not specific for those groups, since they effected nodules on plantlets of certain species assigned to other cross-inoculation groups. There are 15 references.

**The use of enzymes in the preparation of root-tip smears, H. H. MCKAY and A. E. CLARKE.** (U. S. D. A.). (*Stain Technol.*, 21 (1946), No. 3, pp. 111-114, illus. 1).—A simple root-tip smear method for studying somatic chromosomes of *Allium* is described by which an aqueous solution of colchicine and Pectinol (a proprietary enzyme preparation) is used. The root tips are held in a 0.2 percent aqueous colchicine solution for 30 min., fixed in propionic-alcohol solution, run through a graded series of alcohols, washed thoroughly, treated with a 1 percent aqueous solution of Pectinol for 1 to 1.5 hr., and allowed to stand in water for 3 to 5 days to soften. A thin transverse section through the meristematic portion of the root tip is then smeared on a slide in a drop of propionocarmine stain in the usual way and sealed. The schedule presented has been tested with *Allium* only, but presumably may be adapted for use with root tips and similar tissues of plants other than those of the onion genus.

**The influence of the composition of the medium on growth in vitro of excised tobacco and sunflower tissue cultures, A. C. HILDEBRANDT, A. J. RIKER,**

and B. M. DUGGAR. (Wis. Expt. Sta. et al.). (*Amer. Jour. Bot.*, 33 (1946), No. 7, pp. 591-597, illus. 3).—The effects on growth of over 8,000 tissue cultures each of tobacco and sunflower in the first passage were studied in 108 media with increasing and decreasing concentrations of the constituents of the basal medium, plus ferric tartrate, pyridoxine, and nicotinic acid. In addition the combined good qualities of new media were studied with 2,000 and 4,500 cultures, respectively, of sunflower and tobacco tissue. Results indicated that the concentrations of many of the constituents of the basal medium should be increased. Ferric tartrate proved a better source of Fe than ferric sulfate. The omission of sucrose, Fe, and sodium dihydrogen phosphate resulted in poor growth of tobacco tissue cultures in the first passage. There was also less growth when  $\text{KNO}_3$ ,  $\text{Ca}(\text{NO}_3)_2$ , and KI were omitted. The omission of sucrose and sodium dihydrogen phosphate resulted in poor growth of sunflower tissue cultures in the first passage. When ferric tartrate,  $\text{Ca}(\text{NO}_3)_2$ , KI, and boric acid were omitted, less growth appeared than on control cultures. Pyridoxine was apparently favorable to growth of sunflower tissue. Formulas of the improved media for tobacco and sunflower tissue cultures are presented.

**Nitrogen metabolism of corn (*Zea mays*) as influenced by ammonium nutrition.** F. G. VIETS, JR., A. L. MOXON, and E. I. WHITEHEAD. (S. Dak. Expt. Sta.). (*Plant Physiol.*, 21 (1946), No. 3, pp. 271-289, illus. 4).—Corn plants previously depleted in soluble N compounds and showing N-deficiency symptoms on the lower leaves rapidly absorbed N from a complete nutrient solution containing  $(\text{NH}_4)_2\text{SO}_4$  and continued to increase in weight. In time studies in which the  $(\text{NH}_4)_2\text{SO}_4$  concentration was gradually increased to produce toxicity symptoms, injury failed to appear until the soluble N constituents of the sap had reached relatively high levels; the most notable toxicity symptoms were severe water deficit and necrotic areas on the leaves and leaf tips. Analysis of the expressed sap revealed that large amounts of glutamine, asparagine,  $\alpha$ -amino, and other forms of soluble organic N had accumulated in the roots and tops;  $\text{NH}_4$  did not increase rapidly until the soluble N had reached high values. There was a slight increase in pH of the sap in both roots and tops, but little change in total sugar or "true protein" as determined on dry material. Sap analysis on plants in a similar experiment indicated that part of the increase in soluble N was due to peptides and compounds that formed humin on acid hydrolysis of the deproteinized sap. Only a very small portion of the  $\alpha$ -amino N synthesized consisted of basic amino acids. Undetermined soluble N and alkaloid N remained constant during  $\text{NH}_4$  nutrition. Comparative rates of accumulation of N compounds in the roots and tops suggest that absorbed  $\text{NH}_4$  is metabolized to asparagine, glutamine, and  $\alpha$ -amino N mainly in the roots and subsequently translocated to the shoots. On an N basis, asparagine accumulates twice as rapidly as glutamine; one or more amino acids—other than glutamic and aspartic associated with the amides—may be quantitatively as important as asparagine in the metabolism of  $\text{NH}_4$  by corn. The accumulation of  $\alpha$ -amino N in the apparent absence of net protein hydrolysis is discussed. The true protein level is discussed in relation to water, amino acid, and sugar contents and to current theories of protein regulation. There are 49 references.

**Some effects of altitude and water supply on the composition of *Derris elliptica*.** R. H. MOORE. (P. R. Fed. Expt. Sta.) (*Bot. Gaz.*, 107 (1946), No. 4, pp. 467-474, illus. 2).—When *D. elliptica* was grown in Puerto Rico at elevations of 50 to 2,400 ft. above sea level and in Guatemala at 910 to 4,888 ft., the temperature factor correlated positively with the rotenone and inversely with the reserve carbohydrates in the roots. At elevations favorable to growth, the

accumulation of rotenone was influenced by major variations in water supply, but reserve carbohydrates were altered by relatively minor variations in available moisture. The varietal selection of derris grown in Guatemala appeared to be more adapted to higher variations (ecological sense) than the Sarawak Creeping variety grown in Puerto Rico. The normal effect of age on the percentage of rotenone was apparently obscure at high altitudes. Soil pH (4.7 to about neutral) had no measurable effect on either rotenone or carbohydrate reserves. At favorable altitudes, derris plants flourished in soils of good physical structure and belonging to several different types.

**The effect of top environment and flowering upon top-root ratios.** R. H. ROBERTS and B. E. STRUCKMEYER. (Wis. Expt. Sta.). (*Plant Physiol.*, 21 (1946), No. 3, pp. 332-344, illus. 8).—When 29 species or varieties of plants were grown in long and short photoperiods at minimum (night) temperatures of 55°, 65°, and 75° F. in a uniform soil, different species were found to have characteristic top-root relations. The top-root ratio varied with changes in physiological conditions associated with the seasonal development of the plant. A given external environment such as length of photoperiod or temperature was found not to have a similar effect on the top-root ratio of different species. Many of the species studied grew more roots in relation to the top in cooler than in warmer temperatures; some, however, had fewer roots in relation to top under the cooler temperatures. Likewise, some kinds had smaller top-root ratios in short and others in long photoperiods. The top-root ratio was uniformly larger when the plants came to flower; that is, blossoming plants consistently had fewer roots in relation to the amount of top at a given temperature than nonflowering plants of a given species. It thus appears that the composition and reserve conditions within the top are obviously large—if not the controlling—factors in the production of roots and consequently of the top-root ratio. There are 14 references.

**Photoperiodic response as a factor in choice of plants for testing soil deficiencies.** H. A. BORTHWICK. (U. S. D. A.) (*Soil Sci.*, 62 (1946), No. 1, pp. 99-107, illus. 2).—Although photoperiod may result in very marked differences in the development of many plants, methods are available for largely avoiding or preventing this source of seasonal variability. The purpose of this paper is to discuss such methods and to describe the photoperiodic responses of a number of kinds of plants that have been used or perhaps could be used advantageously for testing soil deficiencies. Considerable attention has been given to the fact that the growth and development of photoperiodically sensitive plants can be regulated to a considerable degree by comparatively simple methods of controlling day length. Photoperiod is much more simply and accurately attainable than the control of many other environal factors in greenhouse experimentation; it can be done automatically in many cases via an electric time switch activating a series of lights. Considerable variation in light intensity is without effect so long as the minimum intensity is above a predetermined threshold value; time of application and duration of the supplemental light are the critical factors. Selection of a test plant should be based on consideration of all the factors influencing its adaptability to a particular test. If the plant selected is not photoperiodically sensitive, this factor needs no further attention; if it is sensitive, its response probably can be regulated by artificial control of the photoperiod. Many workers have demonstrated that plants accumulate materials from the soil at varying rates throughout the season. These rates are probably more closely correlated with the type of development through which the plant is passing at a particular time than with the actual age of the plant. Considerable interest is therefore placed on the advantages resulting from use

of test plants whose development can be rather sensitively regulated by photoperiodic control. If facilities for such control can be provided, these plants are more to be sought after than avoided for test purposes because of the additional information and more dependable results that can be obtained with suitable experimental procedures.

**The relation of photoperiod to the boron requirement of plants, R. MACVICAR and B. E. STRUCKMEYER.** (Wis. Expt. Sta.). (*Bot. Gaz.*, 107 (1946), No. 4, pp. 454-461, illus. 8).—The intensity of boron-deficiency symptoms in soybeans proved much more severe in long than in short days. The reduction of symptoms in short days was due to a diminished B requirement rather than to changes in its absorption. The B content of plants exhibiting severe symptoms of deprivation (long photoperiod) and those showing no gross evidence of deficiency (short photoperiod) was essentially the same; histological examination of the stems confirmed this observation. There was little cellular disorganization in minus-B plants produced under short photoperiods; the deficient plants under long photoperiods, however, exhibited abnormalities, there being a marked increase in vascular tissue resulting from abnormal cambial activity and conspicuous necrotic areas in the phloem region.

**Non-latex rubber in *Cryptostegia*, J. T. CURTIS, R. E. DUNCAN, and R. BLONDEAU.** (Univ. Wis.) (*Amer. Jour. Bot.*, 33 (1946), No. 6, p. 578).—A recent paper by Whittenberger and Kerner (*E. S. R.*, 94, p. 606) on rubber in *Cryptostegia* described the occurrence of globules of a hydrocarbon with the properties of low polymer rubber in the leaf chlorenchyma cells. This contribution presents observations on the occurrence of similar globules in other parts of this plant. The facts that such globules are found in nonchlorophyll-bearing cells, occur in greatest number in old cells, and are absent or rare in young actively photosynthesizing cells would appear to indicate that the reactions involved are not directly correlated with the carbon assimilation mechanism. It is believed that further investigation will be necessary before any definite statement can be made concerning the in vivo synthesis of rubber.

**Contribution to the morphology and anatomy of *cryptostegia* (*Cryptostegia grandiflora*), E. ARTSCHWAGER** (*U. S. Dept. Agr., Tech. Bul. 915* (1946), pp. 40, illus. 25).—This contribution presents the results of a detailed study of the anatomy of *cryptostegia* with special reference to tissue ontogeny. The outer primary phloem consists of two distinct rings; the protophloem contains only a few narrow sieve tubes with the bulk of the tissue maturing into groups of fibers. The second ring of primary phloem is composed of discrete groups similar in composition to the inner phloem but smaller in size. The secondary phloem exhibits a very regular design; most conspicuous are the sieve tubes, starch-storing parenchyma cells, and crystal-bearing cells. The latex system is initiated in the embryo, each initial developing into a branching system ramifying throughout the entire plant. Branches pass freely from the pith into the cortex; they are observed frequently in tangential sections occupying the center of a ray. As the stem increases in diameter the latex cells also expand, since the cells of the cambium region remain meristematic. The latex cells of the secondary phloem of older stems are widely spaced, but, since the ring of secondary phloem is ever expanding, the area occupied by latex cells is not necessarily small. The phelloderm cells of both stem and root subdivide into a network of very small cells, each with a small crystal of calcium oxalate.

**The anatomy of the abnormal swellings on the stems of some varieties of soybeans, B. E. STRUCKMEYER.** (Wis. Expt. Sta.) (*Amer. Jour. Bot.*, 33 (1946), No. 6, pp. 571-577, illus. 19).—The Illini variety of soybean responded to photoperiod as an indeterminate type, blossoming in both long and short days.

The anatomical structure of the fourth internode of normal plants induced to flower was similar to that described for other soybean varieties and other species of plants. In short days with cool night temperatures, swellings of the third and fourth internodes occurred; these bore no relationship to blossoming, since plants in the long days that are normal also have fruits. The diameter of the swollen internode was about three times that of the normal stem; this increase in diameter was due largely to an increase in number and enlargement of the parenchyma cells. Groups of sieve tubes and companion cells formed by the cambium were frequently separated by vascular rays, the cells of which were enlarged and often radially stretched. The cambial region was relatively wide but did not consist of the tabular-shaped cambial cells as seen in transverse section. The cambium adjacent to the phloem appeared to be active, forming secondary phloem tissue. Plants of this nature were also found in the field and are referred to as "duds." Investigations of the swollen internodes showed anatomical conditions to be much like those described for abnormal plants grown in the greenhouse. In addition, there were distinct breaks in the vascular region of these stems, leaving spaces into which parenchyma cells were later differentiated. On comparisons of the structure of these abnormal internodes with stems of different species treated with growth substances by others, it appeared that stems treated with these substances show much proliferation of cells and meristematic activity, whereas in the stems here studied, the increase in diameter was to a large extent the result of an increase in size of the parenchyma cells and to some extent of an increase in cell number.

**An oxidation and adsorption reaction for differentiating the endodermis and the collenchyma.** D. S. VAN FLEET. (Univ. Mo.) (*Stain Technol.*, 21 (1946), No. 3, pp. 95-98, *illus.* 4).—The method described was found useful in histologically isolating these tissues, particularly where the accepted anatomical features and the usual staining reactions are not definitive. The exclusive oxidation of the leuco (reduced) form of common redox indicators to the colored (oxidized) form by the endodermis may be induced by treating free-hand or freezing-microtome sections with various alkaline salts at pH 8.5 to 9. Placing sections in sodium borate or sodium selenite induces an immediate oxidation of a tincture of gum guaiac in the endodermis and, after several minutes, a gradual and weak oxidation in the collenchyma. Addition of glycerol to sections exhibiting oxidation in the endodermis induces a localized adsorption of the oxidized indicator in the collenchyma. The endodermis and the collenchyma may be differentiated best by oxidation and adsorption, respectively, via sodium selenite, guaiac, and glycerol in the order given. The collenchyma in roots has not yet been defined; the reactions described introduce a new method for studying this tissue. By treating sections with boric acid a gradient in the guaiac reaction appears in the cortex.

**Seed development in *Acalypha rhomboidea* and some other *Euphorbiaceae*.** M. LANDES. (Univ. Wis.) (*Amer. Jour. Bot.*, 33 (1946), No. 6, pp. 562-568, *illus.* 32).

**Types of pods of *Asclepias syriaca* found in Michigan.** F. K. SPARROW. (Mich. Expt. Sta. coop. U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 73 (1946), No. 3, pp. 65-80, *illus.* 5).—In recent years there has been a growing interest in the seed floss of various species of milkweed—accentuated by the outbreak of war which cut off the primary source of kapok—the East Indies. Descriptions and illustrations are given of 49 distinct types of pods of *A. syriaca* collected from 12 counties in the Lower Peninsula of Michigan; these by no means exhaust the number of types to be found in this region. The presence of so many different types within a very limited area suggests that they represent genetic entities rather than environal variations.

## GENETICS

**Evaluation of some clones of *Derris elliptica*, M. A. JONES, D. G. WHITE, and C. PAGAN.** (P. R. Fed. Expt. Sta.). (*Trop. Agr. [Trinidad]*, 23 (1946), No. 5, pp. 89-93, illus. 1).—In this study of the criteria for derris clones the main consideration at present—with some limitations—should be the yield of rotenone per plant or per acre; secondary desiderata, the quality and yield of root. The possibility of ranking clones of a variety was explored with the result that—by use of the proper experimental design—it became possible to show differences, some of them highly significant, among them. In the selection work on this material several stages were realized: The original choices were made by the Chinese gardeners in Changi. The second segregations were made at the Goodyear plantation in Sumatra, where again the low-grade selections were discarded. At this station nine clones of the best selections were evaluated twice. The first ranking, made at the time the plants were 2 yr. old, was found to agree fairly well with that made in a complete harvest after the plants had been in the field 4 yr. Further confirmation of the ranking obtained remains to be done, especially under conditions in which large-scale production is anticipated. It was shown that the large roots contained the major portion of the rotenone present in the root system. The inverse relationship between root quality and yield is discussed.

**Artificial and natural hybrids in the Gramineae, tribe Hordeae.—II, Agropyron, Elymus, and Hordeum, G. L. STEBBINS, JR., and J. I. and R. M. VALENCIA** (Univ. Calif.). (*Amer. Jour. Bot.*, 33 (1946), No. 7, pp. 579-586, illus. 17).—A continuation of this series (E. S. R., 95, p. 648).

**Comparative rates of pollen tube establishment in diploid and tetraploid maize, J. M. GREEN.** (Iowa Expt. Sta. coop. U. S. D. A.) (*Jour. Hered.*, 37 (1946), No. 4, pp. 117-121, illus. 1).—Monoploid ( $n$ ) pollen was found to become established faster than  $2n$  pollen on both diploid and tetraploid silks, but the time required for establishment of either pollen was not affected significantly by the kind of silk it was germinated on. Indications were that  $n$  and  $2n$  pollen absorb water at a similar rate during the first minute of immersion in water and sucrose solutions of low concentrations. The pollen known to become established more rapidly,  $n$  and  $Wx$ , had higher osmotic pressure than  $2n$  and  $wx$ , respectively.

**A second factor for subcoat in sorghum seed, J. C. STEPHENS.** (U. S. D. A. and Tex. Expt. Sta.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 4, pp. 340-342).—Presence or absence of subcoat, the layer of thick brown cells originating from inner integument and located immediately outside the aleurone of sorghum (*Sorghum vulgare*) seed, is determined by complementary genes. The first factor pair was called  $Bb$  (E. S. R., 51, p. 29), and it is suggested the second pair be designated  $B.b.$  The  $B.b.$  genes appeared to be inherited independently of those for awns ( $Aa$ ), male-sterile-2 ( $Ms.ms.$ ), plant color ( $Pp$ ), dry foliage color ( $Rr$ ), green-striped ( $Gggs$ ), midrib ( $Dd$ ), and waxy endosperm ( $Wwax$ ).

**Mutation in certain phytopathogenic bacteria induced by acenaphthene, P. A. ARK.** (Univ. Calif.) (*Jour. Bact.*, 51 (1946), No. 6, pp. 699-701).—Acenaphthene-saturated broth proved capable of inducing permanent mutations in *Phytomonas michiganensis* and *Erwinia carotovora*. Some mutants of *E. carotovora* possessed a reduced pathogenicity for carrot roots, and one mutant of *P. michiganensis* was nonpathogenic. Acenaphthene did not act alike on all species of bacteria.

**A method of evaluating production inheritance, E. G. MISNER.** ([New York] Cornell Sta., A. E. 554 (1946), pp. 54, illus. 18).—To facilitate the analyses

of production records in the pedigree of an animal, the author has devised a special form in which the ancestors are given codes which consist of a number and an alphabetical symbol. All males are given Roman numerals commencing with I for the sire, II for the sire's sire, and then proceeding with numbers from top to bottom of the old-style pedigree. All females are given Arabic numerals beginning with 1 for the dam and continuing with 2 for the sire's dam and so on from top to bottom. The sires and dams of female ancestors have odd numbers while the sires and dams of male ancestors have even numbers. The code number of the sire and of the dam of each male ancestor in the pedigree is twice the number of the male, and that of the dam for each female ancestor in the pedigree is twice the number of the female plus 1. All ancestors on the sire's side of the pedigree are given S as the first letter and all on the dam's side the letter D as the first letter of an alphabetical symbol to accompany the number. All males have the letter S and all females the letter D as the last letter of the symbol. For the parents of an animal, therefore, the alphabetical symbol is the same as that of the animal plus S if the sire or plus D if the dam of the animal. The methods of analyzing production records in a pedigree are explained, with numerous illustrations. A production inheritance index is set up, and the factors governing the selection of a herd sire are discussed.

**Chance as a cause of changes in gene frequency within pure breeds of livestock, J. L. LUSH.** (Iowa Expt. Sta.). (*Amer. Nat.*, 80 (1946), No. 792, pp. 318-342).—Following a discussion of the influence of migration, mutation, and selection on the pure breeds of livestock, the author considers how chance can affect gene frequency, taking up variations in the number of offspring per parent, emphasis on one ancestor in selections, functional stratification of purebred herds, nonrandom mating, and that actual amount of random change in gene frequency.

It is concluded that chance deviations in gene frequency from one generation to the next, as a result of Mendelian sampling and the elimination of potential parents, are important in the pure breeds of livestock. Standard deviations of the order of 0.02 to 0.05 for gene frequencies near 0.5 seem to be about the usual magnitude of these chance changes in one generation. The major cause for these changes being so much larger than would be required automatically by the finite size of the population seems to be inequality in the number of gametes which the various potential parents actually contribute to the next generation. "Attention to family and pedigree, plus the economic incidents which happen to whole herds, probably emphasize this more in livestock than is usual in most species in nature, although this statement about purebred livestock as compared with wild species is an expression of faith which might be severely shaken if we knew more about the actual pedigrees of wild organisms."

**The use of improved sires, C. C. HAYDEN** (*Ohio Sta. Spec. Cir.* 73 (1946), pp. 67, illus. 30).—This is a brief history of the 13 Jersey and 10 Holstein-Friesian sires used in the station herds over a period of about 40 yrs. as based on records of breeding and production in these herds since about 1904. An attempt was made to eliminate interfering factors such as disease, experiments with restricted rations, and others. The results are deemed about what dairymen may expect from the use of sires selected as calves, even when they are backed by good records.

"The daughters of only the first 3 Jersey and the first 4 Holstein sires averaged below 300 lb. of fat as heifers milked twice daily. A heifer which exceeds 300 lb. of fat under these conditions is not a bad heifer."

**A recurrent mutation of dominant achondroplasia in cattle, S. W. MEAD, P. W. GREGORY, and W. M. REGAN.** (Univ. Calif.) (*Jour. Hered.*, 37 (1946),

No. 6, pp. 183-188, illus. 2).—A dominant mutation that reduces skeletal development was studied in a herd of cattle in Sonoma County, Calif. Heterozygous animals may be recognized by lack of height, occasioned largely by short legs. In the homozygous state there is marked achondroplasia, which is lethal. The mutation occurred spontaneously in one bull whose parents were normal in size.

**Developments in artificial insemination of dairy cattle, J. A. HENDERSON.** (Univ. Ill.) (*Cornell Vet.*, 36 (1946), No. 2, pp. 118-137).—This is a discussion of the development of organized insemination since 1939.

**Comparison between intracervical and intrauterine methods of artificial insemination, A. F. HOLT** (*Vet. Rec.*, 58 (1946), No. 29, pp. 309, 310).—An analysis of records with two bulls at a commercial artificial insemination center in South Devon showed 56.1 percent of conceptions in 374 first inseminations by the intrauterine method as compared with 33.4 percent in 377 inseminations by the intracervical method.

**A synthetic pabulum for the preservation of bull semen, P. H. PHILLIPS and R. R. SPITZER.** (Wis. Expt. Sta.) (*Jour. Dairy Sci.*, 29 (1946), No. 7, pp. 407-414).—Observations pertinent to the storage of bovine semen are reported, on the basis of which a synthetic pabulum for bull sperm storage is suggested. "Its essential ingredients should include freshly purified lipids, specific sugars—glucose and galactose—a buffer system, a gum to supply the proper physical consistency, and an agent to control bacterial contamination."

**Factors affecting productivity in breeding sheep, L. M. WINTERS, D. L. DAILEY, O. M. KISER, P. S. JORDAN, R. E. HODGSON, and W. W. GREEN.** (*Minnesota Sta. Tech. Bul.* 174 (1946), pp. 28).—The records of performance of 603 ewes are analyzed in regard to methods of appraisal and as to the influence of various factors on productivity.

"It was found that the less precise methods of appraisal yielded essentially the same information as the more refined methods regarding which ewes should be retained in the flock. The production per 100 lb. of ewe is, therefore, recommended as the most generally useful method of calculating data.

"The factors having greatest influence on productivity are twins, survival, market grade of lambs, fleece weight, and lamb weight for age. The factors rank in importance in about the order given. This is a point, however, on which it is impossible to be definite, because the weights of the various factors will differ from flock to flock. Fleece weight and lamb weight for age appear to be of more importance in comparisons between breeds than within breeds. Weight of ewe, often considered of major importance, was found in this study to be a minor factor and perhaps of no importance excepting as it may affect the type of lamb produced."

The data presented indicate that breed differences extend beyond the more superficial characters such as face markings, type of ear, etc., and into the factors of major importance affecting productivity. The effects of crossbreeding on productivity were most favorable when rams of the larger breeds were used.

A method of gathering performance data on sheep is proposed. It is further suggested that the objective in sheep breeding for the Middle West should be the development of a ewe that will produce an average wool clip of 9 lb. per 100 lb. of ewe and that will lamb and raise twin lambs that weigh 90 lb. when 20 weeks old and possess sufficient quality to "top" the market.

**Environmental temperature and thyroid gland involvement in lowered fertility of rams, R. BOGART and D. T. MAYER.** (*Missouri Sta. Res. Bul.* 402 (1946), pp. 43, illus. 18).—Continuing the investigations on "summer sterility" in rams initiated by McKenzie et al. in 1937 (*El. S. R.*, 78, p. 181), seven techniques for the evaluation of semen were employed in a comparison of semen specimens from

rams before and after exposure to prolonged periods of high summer temperatures. Semen so exposed differed from that of normal rams in its possession of a decreased volume, a lowered rate of spermatozoan motility, a markedly decreased number of spermatozoa, a larger number of morphologically abnormal and dead spermatozoa, and of a lesser number of resistant or physiologically normal cells.

It is concluded that "high summer temperatures are a major factor in the production of a temporary sterility (summer sterility) in rams. Less extreme variations in the reproductive activity of rams reflected by fluctuations in certain semen characteristics are apparently associated with environmental temperature changes even during the period of summer sterility.

"Thyroxine or thyroid-active protein, administered orally or by injection, alleviates those symptoms of summer sterility resulting from impaired spermatogenic activity, but neither substance has any effect upon those symptoms of summer sterility correlated with a decline of the activity of the interstitial tissues. Administered thyroid-active substances eliminate those fluctuations in semen characteristics which are associated with slight variations in environmental temperature.

"Changes in reproductive activity and in semen characteristics similar to those typical of summer sterility are induced during the fall breeding season by the administration of thiouracil through feeding or by injection. Thyroxine or thyroid-active protein in adequate quantities counteracts the detrimental effects of thiouracil upon reproductive activity.

"It is concluded that the thyroid gland is of major importance in the reproductive physiology of the ram. Further, it may be concluded that changes in environmental temperatures produce variations in reproductive activity in the ram indirectly through the thyroid gland."

**Effects of some environmental factors on weanling traits of range Columbia, Corriedale, and Targhee lambs,** L. N. HAZEL and C. E. TERRILL. (U. S. D. A.) (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 318-325).—The effects of sex, age of dam, type of birth, age at weaning, and percentage of inbreeding were studied on 478 Columbia, 288 Corriedale, and 366 Targhee lambs raised in 1941 and 1942 at the U. S. Sheep Experiment Station. Differences in weaning weight between ram lambs and ewe lambs, lambs from mature and 2-year-old dams, and single and twin lambs were 10.8, 8.7, and 11.7 lb., respectively. Ewe lambs, lambs from mature dams, and single lambs had longer staple and were given higher type and condition scores than the contrasting groups. Face covering and neck folds were not strongly influenced by any of the factors. Merit in each of the traits increased with age at weaning, as indicated by regression coefficients. Inbreeding had a noticeably detrimental effect upon weaning weight, body type, and condition, but not upon length of staple.

**Induction of mating and lambing in anestrus ewes following pregnant mare serum administration,** G. W. VAN DER NOOT, R. P. REECE, and W. C. SKELEY. (N. J. Expt. Stas.) (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 313-317).—When 177 anestrus ewes received either one or two injections of pregnant mare serum (250-350 rat units), 186 came into estrus and mated, 22 following a single injection and 114 following a second injection usually made 16 days after the first. Of the 70 ewes which lambed, 5 had received one and 65 two injections.

**Fertility and hatchability of the prematurely ovulated hen's egg,** B. H. NEHER and B. M. FRAPS. (U. S. D. A.) (*Jour. Expt. Zool.*, 101 (1946), No. 1, pp. 83-89).—Continuing earlier studies (E. S. R., 89, p. 48), the results demonstrated that the first egg of a hen's clutch can be fertilized and reach advanced embryonic development when forced, by the intravenous injection of male chicken anterior pituitary hormone, to ovulate 30 hr. prematurely. Of 13 eggs from hens

ovulating 22 hr. prematurely, 9 were fertilized and 6 hatched. At prematurities of 6 and 14 hr., there was practically no difference in fertility and hatchability between 38 prematurely ovulated eggs and 102 normally ovulated control eggs. When ovulation was forced by prematurities of 22 and 30 hr., many of the resultant eggs were laid prematurely despite the excision of the ruptured follicles both of the forced ovulation and of last normally occurring ovulation. This observation is in contrast with the usual retention of normally ovulated eggs for a day or more beyond time of expected lay following removal of the associated ruptured follicle.

**Insulin-induced rumplessness of chickens, II, III.** ([Conn.] Storrs Expt. Sta. et al.). (*Jour. Expt. Zool.*, 101 (1946), No. 1, pp. 41-50; 102 (1946), No. 1, pp. 1-22, illus. 4).

II. *Experiments with inactivated and reactivated insulin*, W. Landauer and E. H. Lang.—This series (E. S. R., 93, p. 705) was continued to secure information on the chemical nature of the rumplessness-inducing properties of insulin by injecting inactivated and reactivated insulin preparations into White Leghorn eggs. It was found that complete inactivation of insulin with iodine is associated with loss of those of its properties which interfere with normal rump development. Reversible inactivation of insulin with methyl alcohol and hydrochloric acid was about 95 percent complete. Injection of this reversibly inactivated insulin resulted in an incidence of rumplessness which was slightly, but significantly, higher than that expected from an active insulin solution of corresponding potency. Reactivation of the reversibly inactivated insulin with sodium hydroxide led to complete recovery of the insulin activity in the fraction isolated. Reactivation reestablished completely the rumplessness-inducing properties of insulin; in fact, the injection of such reactivated insulin solutions was followed by a slight, but significant, excess in the incidence of rumplessness as compared with the effect of an active insulin solution with identical potency. It is concluded that the effect of insulin on rump development is mediated by the molecule as a whole.

III. *The relationship of dosage and of developmental stage at time of injection to response*, W. Landauer and C. I. Bliss.—In this part the relation of dosage to incidence of rumplessness was tested over a range of 0.05 to 5.0 units per egg on White Leghorn stock and between 1 and 5 units per egg on creeper stock. The insulin was injected into the eggs before the start of incubation. When percentage rumplessness was transformed to probits and the dose of insulin to logarithms, the observations in both series could be fitted by straight lines, incidence of rumplessness increasing with dosage of insulin. The dosage-response curve for creeper eggs was parallel to, but considerably lower than that for Leghorn eggs, indicating that the response of creeper embryos is considerably less than that of Leghorn embryos over the range of tested doses of insulin.

Experiments in which a standard amount of insulin (2 units) was injected at different times after the beginning of incubation showed that the incidence of rumplessness rose slowly to a maximum at about 31 hr. of incubation, after which it tended to drop. The rumplessness-inducing effect of insulin approached zero at about 72 hr. of incubation. These conclusions apply to both Leghorn and creeper embryos. The response of creepers was lower than that of Leghorns at all developmental stages.

As measured by embryonic mortality during the first 6 days of development insulin was less toxic to creeper than to White Leghorn embryos. This was true whether the insulin was injected prior to incubation or at various stages during the first 3 days of development.

In White Leghorn stock selected for a high and low response to insulin, respectively, it was found that insulin injection after 2 or 4 hr. of incubation

resulted in a significantly higher incidence of rumplessness in embryos of the high response line. The lower response line, however, exhibited higher early embryo mortality.

**The production of twins in *Gallus domesticus*, P. D. STURKIE.** (Ala. Polytech. Inst.). (*Jour. Expt. Zool.*, 101 (1946), No. 1, pp. 51-63, *illus.* 3).—Continuing a study by Sturkie and Williams (*E. S. R.*, 94, p. 327), this article deals with the effects of changes in body temperature of the hen upon subsequent development of the embryo, with particular references to the production of duplications and abnormalities. Hypothermia was induced in hens from the time of laying up to 7 hr. after laying of the previous egg, or before and during ovulation of subsequent ova, and during the early cleavage stages. The sub-normal body temperature was maintained from 1 to 4½ hr. and ranged, in most cases, from 36.7° to 38.3° C. When the cold treatments were terminated, the birds were warmed, and most of them had regained normal body temperature within 1 hr. after the end of the treatments. The eggs were taken from the hens the day following the treatment, 24½ to 25½ hr. from the time of laying of the previous eggs. Some of them were set as soon as laid and others were held at room temperature for 24 hr. before incubating. After incubating at 37.5° for 44 to 72 hr., the eggs were opened and the embryos examined.

Among a total of 73 embryos studied, there were observed 6 cases of duplication, or an incidence of 8.2 percent. Five of these duplicities resulted from a treatment in which case the hypothermia was induced and terminated in most hens before the onset of the first cleavage division. Twenty-four of the embryos studied showed abnormalities other than doubling, and 43 were normal morphologically but retarded in development.

## FIELD CROPS

**Designs and technic for the adaptation of controlled competition to forage plant breeding, W. KELLER.** (U. S. D. A. coop. Utah Expt. Sta.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 580-588, *illus.* 4).—Arrangements of plants, suggested as a means of introducing both intra- and inter-specific competition into the breeding nursery, consist of placing single plants of from two to five species in such a way that each plant is adjacent to at least one plant of its own species and at least one plant of each of the other (one to four) species. By one type of arrangement each plant has four direct competitors and by another type six. Guides, described, greatly simplify the mechanics of planting. The method provides a means of working simultaneously with all of the species (up to five) of both grasses and legumes desired in the pasture mixture.

**Straw strength of small grains, H. H. LOVE.** ([N. Y.] Cornell Expt. Sta.) (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, p. 9, *illus.* 2).—A simple apparatus for testing strength of straw enables the selection of varieties of small grain resistant to lodging. Comparisons are made of the merits of the resistant Wong barley and Poland (which lodges badly) and of Cornell 595 v. Michikof wheat. In general, varieties having the highest weight of 100 straws required the greatest weight to break them.

**Effects of lime, fertilizer, and preceding legumes on the yields of corn and tobacco: Experiments on Sango silt loam at Mericourt Station, Clarks-ville, C. A. MOORE and O. H. LONG** (*Tennessee Sta. Bul.* 200 (1946), pp. 12, *illus.* 4).—Yields are reported for corn, tobacco, soybeans, wheat, alfalfa, Korean and sericea lespedeza, and red clover and grasses grown for 10 yr. in 5 crop rotations on a very poor soil (deficient in lime and usual fertilizer elements) limed and treated with superphosphate and potassium chloride and sulfate. Average increases in yield in response to lime and K, respectively, were for

clover-and-grass hay 117, 123 percent, Korean hay 94, 16; sericea hay 38, 17; soybean hay 35, 40; wheat 37, 0; and corn 29, 6 percent. No alfalfa was obtained without lime, and it made 54 percent response to K. Tobacco showed no average gains for lime, but received good indirect effects from liming of alfalfa and sericea. Its response to K was 36 percent. In the first cycle of the rotation, consistent relationship was slight between preceding legumes and the comparative ranking of the following corn and tobacco. In the second 5 yr. corn did best after alfalfa, clover-and-grass, and sericea, and tobacco after alfalfa, sericea, and clover-and-grass in order. Sericea was deemed much superior to Korean lespedeza as a crop for soil improvement.

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 4, pp. 1, 2, 5, 8).—Progress results from agronomic investigations are reported in articles entitled: Alyce Clover in Tests by Substations, by H. W. Bennett (pp. 1, 2); Time of Transplanting Important for Sweetpotatoes, by W. S. Anderson (pp. 1, 5); and Deep Placement of Fertilizers Used as a Side Dressing, by W. B. Andrews (p. 8).

Pollination, *Lygus* infestation, genotype, and size of plants as affecting seed setting and seed production in alfalfa, J. W. CARLSON. (U. S. D. A. and Utah. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 6, pp. 502–514, illus. 2).—Genotypes and individual plants of alfalfa were shown to vary widely in seed setting. The structure of the alfalfa flower favors tripping and cross-pollination by wild bees and honeybees, although relatively efficient seed setting is obtained for some plants with self-pollination associated with conditions favoring automatic tripping. Potential seed production capacity of genotypes and individual plants seems to be associated closely with response to artificial cross-pollination. Response to self-pollination with artificial tripping seems to have predictive value. High yields and maximum production of seed appear to depend also upon an adequate size and large physical capacity of the plants for seed production. Importance of size, however, may be limited to conditions favoring efficient pollination and seed setting. *Lygus* infestation, if uncontrolled, may reduce profitable production of seed about as effectively as does artificial exclusion of pollinating insects. Significant negative correlation was shown between percentage of flowers tripping and *Lygus* populations of plots receiving different insecticidal treatments.

Influence of tripping, soil moisture, plant spacing, and lodging on alfalfa seed production, H. M. TYSDAL. (U. S. D. A. and Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 6, pp. 515–535, illus. 2).—In seed-production studies with alfalfa, 1938–40, an average of less than 5 percent of the flowers set seed without tripping. Rain, sun, and wind might cause some tripping, and a limited amount of self-tripping and setting seed occurs without it. However, such tripping and seed setting is relatively unimportant for seed production compared to the tripping and crosspollination caused chiefly by beneficial insects, including wild bees, honeybees, and a few other insects which are insufficient in practically all fields at the present time.

Plants grown in the greenhouse in 3-gal. jars with high soil moisture content produced more seed than those grown at medium or low soil moisture. Plants growing in soil relatively low in moisture content in the field produced more seed than those in high moisture, when spaced 8 in. each way. Spaced 32 in., however, low and high soil moisture plots made about the same amount of seed, indicating that high soil moisture content, as such, is not an inhibiting factor. Lodging plants at time of bloom by bending and fastening down the stems greatly reduced seed production as compared to upright plants. Lodged plants produced much more new growth, as shown by many more stems per plant, and produced 20 percent shriveled seed compared to 5 percent for upright plants.

**Alfalfa in Kansas**, C. O. GRANDFIELD and R. I. THROCKMORTON. (Coop. U. S. D. A.). (*Kansas Sta. Bul.* 328 (1945), pp. 64, illus. 28).—Recent information provided on alfalfa production in Kansas is based on prolonged research at the station and elsewhere, and extensively noted. Topical discussion is accorded alfalfa investigations; production, including soil preparation, seed and seeding, and cultivation; varieties, covering the commonly grown and new varieties, variety tests, and group classification; time of cutting for hay, seed, silage, and other products; harvesting for hay and for seed; alfalfa for pasture and grass mixtures; and the control of diseases, insects, and rodents attacking alfalfa.

**Bahia grass types**, G. W. BURTON. (U. S. D. A. coop. Ga. Coastal Plain and Ga. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 3, pp. 273-281, illus. 3).—Bahia grass, *Paspalum notatum*, is not a native of the United States. Strains discovered in the United States to date might be grouped into six types, Common, Wallace, Paraguay, Wilmington, Pensacola, and Tampa, which types differ greatly in leaf size and shape, rate of spread, earliness, seed and forage production, floret size and shape, fertility, frost resistance, winter survival, sod density, and palatability. Twenty somatic chromosomes were found in root tips of Pensacola Bahia; all other Bahia types studied had 40 as the  $2n$  number. Common Bahia has been intentionally introduced by man from many different parts of the tropical portion of the Western Hemisphere, whereas limited distribution of the other types around southeastern seaports suggests their introduction by chance in ballast and packing of early seaborne cargos. Texas strains seemed identical with an introduction from Paraguay, Pensacola Bahia resembled an Argentina introduction very closely, and Tampa Bahia appeared very similar to numerous herbarium specimens from the West Indies.

**The course of the pollen tube in cultivated barley**, M. N. POPE. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 5, pp. 432-440, illus. 17).—Germination of the pollen grain occurs on the stigma hair, and the tube enters the central lumen through the angle between the papilla and the base of the cell just above. The tube, pointed downward, traverses the hair down into the style. Enlargements of the tube may occur while it pushes its way between the cells of the style and those of the ovary wall. The tube resumes its normal diameter as soon as a path through an obstruction has been made. As it enters the ovary, the pollen tube passes along the S-shaped band of conducting tissue to the cone-shaped projection of the outer integument on the upper end of the ovule, thence between the inner epidermis of the ovary wall and the outer integument, over the abchalazal surface of the ovule, through the micropyle. It then pierces the wall of the nucellus and discharges the male nuclei into the embryo sac. The barley ovary is described.

**Growing winter barley in New Jersey**, R. S. SNELL, C. S. GARRISON, and G. H. AHLGREN (*New Jersey Stas. Bul.* 727 (1946), pp. 28, illus. 15).—Popular information is given on the status of winter barley in New Jersey, value for feed, cultural and harvest practices, and control of insects, and reports are made on results of variety and planting tests. Production must exceed average State yields of 30 bu. per acre if winter barley is to be profitable as a cash crop where the grain is sold for feed. If used for feed and straw on the farm where produced, barley is of much greater value than if marketed for cash. Wong barley, found the most productive of grain and straw of any variety tested, excels in resistance to mildew and lodging, has erect spikes, and is comparatively easy to combine. It needs more fertilizer than other varieties for maximum performance. Maryland Smooth Awn, the earliest maturing barley tried, probably surpasses Wong as a companion crop in seeding down to hay or pasture. Ken-

tucky 1, the winter-hardest in tests, may be of most value in northern New Jersey counties where winter-killing remains a problem.

October 1 appeared in station tests to be the latest date for satisfactory plantings. A seeding rate of 2 bu. per acre was indicated as most favorable with September plantings. Higher rates than 2 bu. have partly compensated for later planting. Damage from hessian fly might be minimized by seeding from September 10 to 20 in central New Jersey and from September 20 to 30 in southern New Jersey.

**Use of the natural crossing plot in making castor bean hybrids,** R. O. WEIBEL and C. M. WOODWORTH. (Ill. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 6, pp. 563-565, illus. 1).—The facts that the castor-bean is wind-pollinated and the pistillate and stamen flowers are borne separately on the spike, the former above the latter, permit the use of crossing plots in making hybrids. Staminate flowers are easily removed before pollen is shed. The male and female parents planted in alternate rows in plots of 10 to 14 rows 2 rods long, isolated by spotting in cornfields, produced relatively large amounts of crossed seed and pure seed of the male parent.

**Early testing of inbred lines of corn,** G. F. SPRAGUE. (Iowa Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 108-117, illus. 2).—When 167  $S_0$  plants from a stiff-stalked synthetic corn were self-pollinated and top crossed on Iowa Hybrid 13, highly significant differences were obtained among yields of these top crosses.  $S_1$  plants of two samples selected from the population of selfed plants on the basis of top-cross yield, the upper 10 percentile, and a seriated sampling of the frequency distribution, were self-pollinated and out-crossed to the tester. In the 10-percentile sample top cross, yields were equal to the mean of the selected parents. In the seriated sampling, correlation between  $S_0$  and  $S_1$  top-crossed yields was +0.85. Three  $S_2$  lines tested in single crosses averaged better in performance than the five standard commercial lines with which they were compared.

**Tests of corn hybrids and varieties in Mississippi, 1945,** R. C. ECKHARDT, W. A. DOUGLAS, and A. L. HAMNER. (Coop. U. S. D. A.). (*Mississippi Sta. Bul.* 427 (1946), pp. 10).—Outstanding corns in results of State-wide tests included Mississippi experimental hybrid 5111; La. 468, 1030, and 502; N. C. 5001 and 4003; and Funk G714 hybrids, and the open-pollinated Station Mosby, Station Laguna, and Jellicorse varieties. Yields and other agronomic data are tabulated by locality and also in summary tables.

**Distribution of corn plants in the field,** G. H. DUNGAN. (Ill. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 4, pp. 318-324, illus. 2).—Grain yields from corn in single-plant hills, 1930-33, 1940-42, were significantly superior on productive soil in seasons with a well-distributed and ample rainfall than from the same population in multiple-plant hills. Single-plant hills had greatest advantage at relatively high plant population rates. Diameter of stalks at their base and stover yield were higher in every test for the single-plant distribution. Single-plant hill plots lodged more and had higher tiller numbers than multiple-plant hill plots. Increases in grain yields for single-plant hills were attained through increases in size of individual ears and in number of ears per stalk.

**Environmental modification of fiber properties as a source of error in cotton experiments,** D. M. SIMPSON and K. L. HERTEL. (U. S. D. A. coop. Tenn. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 73 (1946), No. 3, pp. 97-111).—Samples of seed cotton were obtained from six varieties at six locations in the Cotton Belt in 1941 and 1942. Pickings were made at regular intervals at each place, so that samples represented production during definite growth periods. Length and uniformity in length were determined by the fibrograph, fineness by the arealo-

meter, and strength of fiber by the Pressley strength tester. Factors involving change of environment, such as location, date of opening, or year of growth, caused wide variation in the physical properties of the fiber of the several varieties. Among the upland varieties, variation within variety due to environment often exceeded the differences between varieties due to hereditary influence. In breeding for fiber quality, unless extreme care be taken in field sampling, environmental factors may introduce bias enough to mask heritable qualities and vitiate conclusions drawn from accurately measured samples.

**Potash and lime requirements of cotton grown in rotation with peanuts,** J. J. SKINNER, W. L. NELSON, and E. R. COLLINS. (U. S. D. A. and N. C. Expt. Sta.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 142-151, illus. 2).—Yields of cotton in studies 1938-43 were significantly increased on Norfolk very fine sandy loam, Ruston loamy sand, and Craven and Lenoir fine sandy loams by the use of 48 lb. of  $K_2O$  per acre in a complete fertilizer as compared to 24 lb. Wickham sandy loam, which gave no significant response, contained 0.19 m. e. of exchangeable K. The other soils contained 0.07-0.10 m. e. The 48 lb. of  $K_2O$  applied directly to cotton gave higher cotton yields on all soils than 25 lb. or 50 lb. of  $K_2O$  to peanuts in addition to 24 lb. to cotton. Peanut yields were not affected significantly by these  $K_2O$  treatments. Neutral fertilizers increased cotton yields on Lenoir fine sandy loam which had a pH of 5.0, 0.24 m. e. of exchangeable Mg, and a saturation of 23 percent with Ca. Dolomitic limestone applied in the row to peanuts also increased cotton yields on this soil.

**The beginnings of crested wheatgrass in North America,** A. C. DILLMAN. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 3, pp. 237-250, illus. 5).—Crested wheatgrass was grown under cultivation in Russia as early as 1897, and the first plant selections of record were made by Russian workers previous to 1906. The first lots of seed brought in by N. E. Hansen in 1898 were distributed to individuals, but did not become established in the United States. The second importations in 1906, listing the two types *Agropyron cristatum* and *A. desertorum*, were distributed widely between 1907 and 1913. The author maintained both types in tests at the Belle Fourche Experiment Farm (Newell, S. Dak.), 1908-20, and supplied seed for planting at the Northern Great Plains Field Station (Mandan, N. Dak.) and at Ardmore, S. Dak. The first planting made in 1915 at Mandan was foundation stock from which seed was first released to farmers in the northern Great Plains. Plant selections made in 1919 at the Belle Fourche Station were grown at Mandan. Some 4,000 lb. of seed, representing four of the better selections, have been produced and distributed to growers. The former view that the two types of crested wheatgrass, *A. cristatum* (S. P. I. No. 19536) with 14 (2n) chromosomes, and "standard" *A. desertorum*, with 28 (2n) chromosomes, are distinct species appears to have been justified. The Fairway variety and S. P. I. No. 19536 appear to be similar or identical strains of *A. cristatum*.

**Response of rotenone-bearing devil's shoestring, *Tephrosia virginiana* (L.) Pers., to fertilizer applications,** G. A. RUSSELL and V. A. LITTLE. (U. S. D. A. coop. Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 646-650).—N, P, and K fertilizers were applied to field plots of devil's shoestrings alone and in combination for periods of 1, 2, and 3 yr. N increased the yield of roots significantly, while K increased root yield and improved their quality as measured by percentage of rotenone and total chloroform extractives. P had no effect on yields of roots but reduced their quality significantly.

**The growth and rubber content of guayule as affected by variations in soil moisture stresses,** A. S. HUNTER and O. J. KELLEY. (U. S. D. A.). (*Jour.*

*Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 118-134, illus. 7).—Irrigation experiments with guayule in its second year of growth in the field were made on Delano sandy loam and Sorrento silty clay loam soils in the San Joaquin Valley, Calif., involving five differential moisture treatments ranging from very high to very low maintained through the growing season. Increases in shrub weight ranged from 1,000 lb. per acre on low-moisture plots to more than 10,000 lb. on those of higher moisture level. Increases in amount of rubber ranged from 190 to 650 lb. per acre on the sandy loam and from 350 to 515 lb. on the silty clay loam. The highest moisture levels on the sandy loam produced the highest yields of shrub and rubber, while on the silty clay loam the highest rubber yield was produced by the lowest moisture level, explainable on the basis of the differences in the moisture retention curves for the two soil types. An inverse relationship existed between dry weight of shrub and percentage of rubber. Fertilizers increased weight of shrub but decreased percentage and absolute amount of rubber. Moisture treatment had slight effect upon the percentage of resin. No noticeable symptoms of guayule diseases resulted from any moisture treatment.

**Increased rubber production from thickly seeded guayule.** O. J. KELLEY, H. R. HAISE, L. C. MARKHAM, and A. S. HUNTER. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 589-613).—Experiments in southern California indicated that for maximum rubber production by guayule, dense stands of plants are to be recommended, especially for short-cycle production. Optimum irrigation and fertility treatments appeared to be related closely to soil and climatic conditions.

**The germination of guar, *Cyamopsis tetragonolobus* (L.) Taub., A. F. MUSIL.** (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 661-662).—A constant temperature of 30° C. appeared to be optimum for satisfactory germination of guar seed in the laboratory. The common late-maturing crop produces a variable proportion of nonviable seed, believed to be the result of frost. An early maturing strain with a high proportion of hard seeds germinated slowly and irregularly. Seed treated 15 min. with 75 percent sulfuric acid gave complete germination in 3 to 6 days. No seedling injury resulted when treatment was prolonged to 30 min. A good field stand may be obtained by pretreating well-matured seed with sulfuric acid and delaying planting until the ground is thoroughly warm.

**Effects of fertilizers on yields and breaking strengths of American hemp, *Cannabis sativa*,** H. V. JORDAN, A. L. LANG, and G. H. ENFIELD. (U. S. D. A. coop. Wis., Ill., and Ind. Expt. Stas). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 6, pp. 551-563, illus. 2).—Hemp made its major response in fertilizer tests to N. On the less productive soils, N increased yields markedly without detrimental effects to fiber quality. On good fertile soils, yield response was small, and both on the fertile soils and where N application exceeded the optimum the reductions occurred in fiber strength, ranging from 4.4 to 14.7 percent. Associated with this effect abundant N caused a more leafy and succulent type of growth and increased stem diameters above the optimum range. The problem in fertilizing hemp seems to be to adjust rates and balances of nutrients so as to insure maximum production and maintain fiber quality. On peat soil in 1943, heavy applications of minerals produced high yields of hemp but the fiber was weak. In 1944 the available N level was reduced by applications of carbonaceous material and minerals were applied. Yield was only moderate but the fiber had good quality.

**The retting of hemp, I-III** (*Iowa Sta. Res. Buls.* 342 (1946), pp. 880-891, illus. 29; 343, pp. 893-924, illus. 16; 344, pp. 825-944, illus. 1).—There are three contributions in this group. See also earlier notes (E. S. R., 94, p. 191).

I. *Field retting of hemp in Iowa*, W. H. Fuller, A. G. Norman, and C. P. Wilsie.—Experiences are reviewed for two seasons of contrast in retting conditions, in that in 1943 much of the commercial crop was insufficiently retted while in 1944 over-retting was common. An analysis of factors involved in field retting as developed from detailed studies of experimental plots in both seasons is included. In the north-central area in Iowa, in which commercial hemp was grown in 1943 and 1944, successful field retting is at best very uncertain. Normal rainfall and moisture conditions in that area are adequate to permit retting to proceed to completion, but great divergences from the normal in both total rainfall and pattern of distribution makes the venture risky. Chances of obtaining a successful crop are good, whereas chances of retting that crop successfully are much poorer. Good hemp could undoubtedly be grown in western Iowa, yet the drier fall conditions that are normal for that area would make retting even more risky an operation than in the other parts of the State. Hemp should be harvested early in September, which should increase expectation of exposure to rain. If retting is proceeding only slowly because of dry weather, and is limited primarily to the top hemp as a result of dew deposition, turning should accomplish a greater measure of uniformity and should be done well before retting of the top hemp is completed, and probably when the dark flecked areas on the straw become numerous. Hemp cut early in September is usually ready to be turned by the middle or the latter part of the month. Turning after October 15 may not be worth while if retting is to be completed by October 31, so that the crop can be picked up early in November. Turning is not essential if retting proceeds fairly uniformly throughout the swath, which is likely to be the case in rainy and humid periods. In harvesting the hemp, every effort should be made to leave as short a stubble as possible, particularly if the harvest is delayed and if the stand is heavy. A short stubble means greater retention of moisture by hemp at the bottom of the swath and consequently a greater likelihood of uniform retting.

II. *Controlled retting of hemp*, W. H. Fuller and A. G. Norman.—Controlled methods of retting in general released a fiber superior in quality and uniformity to that ordinarily obtained by field retting. Retting in tanks under anaerobic conditions was faster than any of the aerobic methods, and produced a fiber with more desirable characteristics. Retting under anaerobic conditions was fastest at 37° C., the acidity of the solution held to a minimum, the solution undisturbed, and an enrichment culture added initially as inoculum in amount equal to 10 percent or more of the total tank solution. The main acids produced under anaerobic conditions were acetic (predominating) and butyric. Some nonvolatile acid was also produced in lesser amount. Acid accumulation and consequent retardation of the retting process was prevented by aeration, and later return of part of the retting solution in a separate tank.

Loss in weight of the hemp and production of volatile acids may be used to a limited extent as indicating rate and degree of retting on a laboratory scale, provided that uniform material of the same source and maturity is used. The end point of retting for hemp of mixed sources, as would be obtained commercially, could not be judged from volatile acid accumulation or loss of weight of straw. A small pilot plant with a capacity of 200 lb. of hemp straw was operated successfully. Anaerobic conditions were maintained in the tank, and acid accumulation was prevented by continuous withdrawal, aeration, and replacement of the tank solution, which was re-used repeatedly.

III. *Biochemical changes accompanying retting of hemp*, W. H. Fuller and A. G. Norman.—Bark from hemp retted in the field and under controlled conditions in the laboratory was analyzed at intervals to follow biochemical changes

occurring during retting. Pure cultures of certain dominant retting fungi were inoculated into sterile hemp bark, and similar analyses were carried out after decomposition was allowed to continue for intervals up to 20 days. Regardless of method of retting or stage of maturity of the hemp, there was considerable early loss of water-soluble constituents, of furfuraldehyde-yielding constituents, and total uronic groups.

Reduction in total uronic content of the bark reflected progress of retting better than that of any other constituent. Well-retted hemp bark had a total uronic content of about 5 to 6 percent as compared to 9 to 10 percent on unretted bark. Under controlled anaerobic conditions about one-half of the water-soluble constituents and the furfuraldehyde-yielding constituents were removed in the first 36 hr. Attack upon cellulose was negligible until after 48 hr. Under field conditions appreciable cellulose utilization was evident when the samples were well retted.

Progress of retting was invariably accompanied by an attack on polyuronide hemicelluloses proportionately as great, or almost so, as that upon pectin. Freeing of the bundles could not be regarded as exclusively a matter of pectin decomposition. No appreciable changes occurred in major constituents of the woody portion of hemp straw during retting. Various fungi in pure culture were quite similar in attacks effected upon constituents of hemp bark. There was no indication that *Trichothecium roseum*, which in the field was suspected to cause fiber weakness, was more vigorous in cellulose decomposition than other organisms normally present on hemp straw.

**Ecological and morphological characteristics of black medic strains,** R. E. BLASER and W. E. STOKES. (Fla. Expt. Sta.). (*Jour. Amer. Agron.* 38 (1946), No. 4, pp. 325-331, illus. 3).—Commercial strains of black medic (*Medicago lupulina*), except Alabama-grown seed, were low yielding, volunteered very unsatisfactorily, bloomed very late, and seeded sparsely when compared with Florida seed sources 1942-44. Plants from commercial seed sources, except Alabama seed, produced leafy, prostrate, rosette plants due to the short internodes. Plants from Florida seed sources (natural stands) had long internodes, a stemmy appearance, and an ascending habit of growth. The commercial strains produced dark green foliage, while the Florida strains were light green, and seed size also differed greatly. Productivity and morphological characteristics and seed of Florida strains also differed, but most of them were adapted to Florida environment.

**The history and evolution of milo in the United States,** R. E. KAEFER and J. R. QUINBY. (Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38, (1946), No. 5, pp. 441-453).—Milo, a group of varieties of *Sorghum vulgare*, was introduced into the United States as Yellow Milo Maize from an unknown source about 1885. Its commercial varieties have comprised 75 to 80 percent of the grass sorghum crop in Texas, and are almost as important in other southwestern States. Comment is made on the genetics of the milo group, varieties arising through mutation and recombination, and root rot-resistant varieties of milo.

**Effect of soil characteristics and fertilization on potatoes as regards yield and tissue composition,** J. M. MACGREGOR and C. O. ROST. (Minn. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 636-645).—Potatoes grown on 12 fields in the Red River Valley (E. S. R. 94, p. 193) in soils ranging from clay loams to sandy loams were fertilized with 125 lb. of superphosphate alone and with 200 lb. of KCl per acre. The fertilizer gave economic increases in yield of tubers but produced no significant change in percentages of Ca, Mg, P, or K in the roots and stems of the plants. Applications of KCl increased Cl uptake with a repression of sulfate. Ca and Mg content rose with increasing concentrations

of soil carbonates with evidence of some phosphate repression. Soluble soil sulfates repressed Cl uptake with the assimilation of larger amounts of sulfate. Tuber yield increased as soil texture became finer with an appreciable increase in the K content of the tops.

**The comparative evaluation of fourteen types of ramie under Cuban conditions,** J. C. CRANE and J. B. ACUÑA. (U. S. D. A. et al.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 2, pp. 152-167).—In a comparison of growth response and fiber production of *Boehmeria utilis*, *B. japonica*, and 12 types of *B. nivea*, three harvests during the year of planting gave total yields of stems and leaves ranging from 15,435 lb. per acre of Antigua de Botanica to 41,367 lb. per acre for de Francia. Type C produced a total of 565 lb. of dry degummed fiber per acre, followed in order by de Francia, 517 lb., and D, 505 lb. Americana was the most prolific stem producer, but had the shortest stems; its prolific habits might be combined with the greater vigor and fiber-producing capacity of types D, C, or de Francia. Average percentage of fiber of the green weight of defoliated stems ranged from 1.5 for type A to 2.8 for type D. Types C, de Francia, and D appeared to be the better adapted in regard to plant growth and yield of fiber in Cuba.

**The effect of plant spacing and time of harvesting on fiber yield of ramie, *Boehmeria nivea* (L.) Gaud.** J. C. CRANE and J. B. ACUÑA. (U. S. D. A. et al.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 3, pp. 225-236).—Plants of type C ramie, the most productive of 14 types tested at the Cuban Agricultural Experiment Station, were set 12, 18, and 24 in. apart in rows 2, 3, and 4 ft. wide. Average production of all spacing treatments from the 90-day harvest was 580 lb. of degummed fiber per acre as compared to 435 lb. for the 60-day harvest, yet the results are deemed inconclusive, due to factors involved. Average production of fiber from all spacings of the 3-ft. width rows of the 60-day harvest was 6 and 24 percent greater than for the 2- and 4-ft. width rows, respectively, and for the 90-day harvest, 8 and 31 percent greater. Slightly larger yields from plants spaced 12 and 18 in. did not pay for the additional plants needed. The percentage of fiber of the green weight of stems did not increase with age of the stem as in some other bast fiber plants. For fiber quality, harvesting should be delayed until the ultimate height of the crop is reached for maximum production of fiber per unit area.

**The effect of straw and nitrogen on the yield and quantity of nitrogen fixed by soybeans,** L. A. PINCK, F. E. ALLISON, and V. L. GADDY. (U. S. D. A.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 5, pp. 421-431, illus. 2).—Yields of inoculated soybeans were decreased significantly by straw applied at time of planting or 6 weeks earlier, due in part to a moderate initial "hunger period." Under conditions favorable for rapid growth, urea increased yields but had little effect upon the total N content of the plants. Urea N was merely used instead of atmospheric N. Delayed planting, following application of straw-nitrogen mixtures, sometimes resulted in very slightly lower yields and N contents of soybeans. Urea depressed N fixation, whereas straw increased it, the maximum being N 165 lb. per acre. Where enough straw was added to inactivate any N present, there was no marked effect of either on N fixation. Carbonaceous crop residues evidently should be used in a legume cropping system, wherever feasible, rather than in a nonlegume commercial N system. Adequate commercial N may sometimes be desirable to decompose crop residues even when a legume is grown.

**2,4-D as a means of controlling weeds on sugarcane lands,** G. ARCE-NEAUX, L. P. HERBERT, and L. C. MAYEUX, Jr. (U. S. D. A.) (*Sugar Bul.*, 24 (1946), No. 9, pp. 65-68, 70).—On sugarcane plots sprayed with 2,4-D in 1945

for control of alligatorweed (E. S. R., 93, p. 283), cane yields averaged slightly higher than yields from plots hoed three times during the growing season and nearly 3 tons of cane and more than 700 lb. of sugar higher than from plots given flame cultivation. Plots of the 2,4-D series also showed the lowest residual weed infestation. Advantages of 2,4-D over other methods tested were especially conspicuous in an experiment on poorly drained Sharkey clay heavily infested with alligatorweed. Destruction of shoots and stunting of growth so harmed the weed that cane plants achieved complete dominance and effectively crowded it out. Neither hoeing nor flaming suppressed the weed enough to permit effective competition by sugarcane plants. Results from the treatments did not differ much on well-drained Yazoo very fine sandy loam with a much lower initial infestation of alligatorweed. Among other weeds commonly infesting growing cane, various species of morning-glory and birdseye (*Capersonia castanefolia*) proved relatively sensitive. In experiments with alligatorweed on ditch banks, ditch bottoms, and fallow areas, 2,4-D applications at appropriate intervals resulted in progressive decimation of underground storage organs. Sprouts that grew after this treatment developed slowly and were readily crowded out by other plants.

A "new" cultivated sunflower from Mexico, C. B. HEISER, Jr. (Univ. Calif.). (*Madroño*, 8 (1946), No. 7, pp. 226-229, illus. 1).—A brief report on a previously unknown cultivated form of sunflower, including comparisons with two other cultivated forms of *Helianthus annuus*. The exact relationship of the Mexican sunflowers to the cultivated forms of the Hopi and to the various types cultivated in Europe and North America can scarcely be discussed in the light of published evidence now available. It is considered highly desirable that additional information be obtained on the primitive sunflowers of Mexico.

Black root rot resistant strains of Havana seed tobacco for the Connecticut Valley, C. V. KIGHTLINGER. (Partly coop. U. S. D. A. and Conn. [New Haven] Expt. Sta.). (*Massachusetts Sta. Bul.* 432 (1946), pp. 20, illus. 6).—Attempts to develop a strain of Havana Seed tobacco satisfactorily resistant to black root rot, yet capable of producing high yields of good quality, are reported with comments on the nature of the disease, its economic importance, and control.

Havana 211, derived from Page Comstock  $\times$  Havana 38, was produced as a result of cooperative breeding work in the Connecticut Valley and in Wisconsin. Havana K2 was developed in Massachusetts from a cross of regular Havana Seed (Sandman strain) onto Havana 211. Havana 211 and Havana K2 equaled or exceeded Havana 142 slightly in gross yielding capacity under black root rot promoting conditions, and surpassed regular Havana Seed considerably under conditions favorable for tobacco. They may be acceptable in productiveness under most circumstances in the Connecticut Valley. Compared with regular Havana Seed, Havana 211 endures drought better, is not so readily attacked by flea beetles and thrips, and matures about 7 to 10 days later. Havana K2 and Havana 211 do not differ greatly in the more evident characteristics of type. It is largely improvements in certain characteristics of type, earlier maturity, better curing, and better sweating or fermenting that suggest the possibility that Havana K2 may be more satisfactory than Havana 211 for general growing in the Connecticut Valley. Havana 211 has been largely instrumental in increasing the cash income of many farmers who grow Havana Seed tobacco.

The Oklahoma farm wheat improvement program: Progress report, 1938-45, R. M. OSWALT. (*Oklahoma Sta. Misc. Pub.* 9 (1946), pp. 7+, illus. 2).—Established in 1937 to improve the quality of wheat grown in Oklahoma, the program (E. S. R., 87, p. 511) has for aims more acres of high quality seed planted; reduction of mixture of wheat with rye and other cereals and smuts; and elimination of varieties of poor bread-making characteristics. Considerable improvement has been made in the quality of Oklahoma wheat since 1937. Growers have

become much more variety conscious, and wheat and rye mixtures have decreased. Farm samples showed an increase in grade A from 1939 through 1943, slightly falling off in 1944 and 1945, probably due to a high demand for all wheat for foreign trade regardless of quality and to the lack of good seed for planting. Average (weighted) acre yields over various periods were for Tenmarq 18.8 bu., Turkey 16.1, Cheyenne 18.1, Blackhull 16.9, Chiefkan 18.6, Early Blackhull 19.2, Comanche 21.6, Pawnee 22.5, Red Chief 20.2, Reliant 21.9, Triumph 21.9, Kanred 13.5, Wichita 22.5, and the soft wheats Kawvale 15.2, Clarkan 16.1, Fulcaster 11.4, and Harvest Queen 13 bu. Comanche, Chiefkan, and Pawnee averaged slightly higher in percentage of protein than Tenmarq, while Turkey, Cheyenne, Blackhull, Triumph, Reliant, Red Chief, and Kanred were slightly lower. Early Blackhull averaged 9 percent lower than Tenmarq in 61 tests. The 4 varieties classed as soft red winter were from 5 to 11 percent below Tenmarq. Varieties found definitely desirable for bread making were Turkey, Tenmarq, Cheyenne, Comanche, and Pawnee, but other varieties also have proved satisfactory. Early Blackhull or Haerberle, Chiefkan, and Red Chief had undesirable bread-making qualities. All of 15 varieties compared 1941-44 except Kawvale were from 1 to 7 percent higher in test weight than Tenmarq. Kawvale was 2 percent below Tenmarq.

**Seed wheat studies stress importance of quality, M. T. MUNN.** (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, p. 8).—Quackgrass, cockle, and hairy vetch were the most widespread impurities found in high quality seed wheat. Many stocks contained light, shriveled kernels due to *Fusarium* blight (scab), and stinking smut was common in all stocks. Chess and cockle were the commonest weeds in samples of wheat delivered to mill from a wide area. Eight of 20 truckloads were too foul with vetch for use as seed.

**The effect of wheat variety upon maltose values, E. G. BAYFIELD.** (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 7, pp. 624-629).—Examination of wheat varieties grown at various Kansas locations 1941-43 indicated that hard flinty varieties, as Chiefkan, were consistently high in maltose value of flour, an important quality factor to the baker, whereas the soft wheat Clarkan gave much lower values. Tenmarq, Turkey, and Blackhull were about equal. Kawvale, officially graded as a soft wheat although not so considered by soft wheat millers, was in the Tenmarq-Turkey group. Maltose value seemed to be an inherited character, although its annual expression was largely modified by environmental factors.

**Wheat viability loss due to fumigation and its relation to baking quality, R. T. COTTON, J. C. FRANKENFELD, E. G. BAYFIELD, and J. A. JOHNSON.** (U. S. D. A. coop. Kans. Expt. Sta.). (*Northwest. Miller*, 227 (1946), No. 2, Sect. 2, pp. 4a-5a).—With excessive dosages or exposure periods, fumigants commonly used to treat wheat in storage may cause loss of viability, particularly if the grain moisture is above 12.5 percent. With ordinary dosages and exposures these fumigants affect temporarily the baking quality of flour made from the wheat, but the effects disappear if the grain is aerated enough. Loss of viability from many causes may impair baking quality, yet these studies indicated that partial or completed loss of viability due to fumigation does not necessarily impair baking quality even after storage of the wheat for 1 yr.

**Period of effective weed control by the use of 2, 4-Dichlorophenoxyacetic acid, P. C. MARTH and J. W. MITCHELL.** (U. S. D. A.). (*Science*, 104 (1946), No. 2691, pp. 77-79).—Results on lawn grass plots indicate that once established weeds have been killed by means of 2,4-D (E. S. R., 93, p. 285) sprays, and young seedling weeds subsequently germinating in surface soil layers have been eradicated by further spraying, it is feasible to maintain a weed-free lawn by

judicious use of 2,4-D. Repeated sprayings have not proved harmful to established grasses, and in the absence of weeds the sod had developed a uniformly dense coverage of the soil surface which in itself tends to discourage infestation by most common lawn weeds. Preliminary results with dry mixtures of fertilizer and 2,4-D were promising for weed control in lawns, pastures, and other grassy areas. This method makes it possible to apply effective weed-killing and fertilizing treatments in the same operation, saving time and labor.

**Weed-free lawns for New York—new acid kills lawn weeds with single application should be used to supplement fertilizer,** A. M. S. PRIDHAM. ([N. Y.] Cornell Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, p. 7, *illus. 1*).—Practices for lawn areas in New York, based on test results and experience, include application of fertilizer in fall and spring at the rate of 20 lb. of 5-10-5 to 1,000 sq. ft., cutting the grass to at least an inch in height, and leaving the clippings on the lawn. 2,4-D is applied in May or June to remove dandelion or plantain, kill young weed seedlings, and halt germination of any remaining weed or grass seed. When lawns are once weed free, fertilization is continued to thicken the turf and to crowd out weed seedlings. Colonies that may become established are spot sprayed or, to be certain, sprayed once a year in late May.

**Ragweed pollen may be eliminated—one application of 2,4-D at proper time sufficient—must be used with care around crop plants,** F. G. SMITH. (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 1-2).—Development of ragweed pollen in both common and giant species has been successfully prevented in test areas by spraying with 2,4-D early in August. Tests showed that the spray must be applied before the pollen-bearing parts of the flower have opened and have begun to ripen, usually August 1-7 in the vicinity of Geneva. Water sprays containing 0.1 percent of 2,4-D and 0.5 percent of Carbowax were effective applied at rates of 100 to 200 gal. per acre. The 2,4-D could also be effectively applied as a fog, using an oil solution of the material in a fog applicator. This method has advantages of swifter application and lower cost and of requiring much smaller volumes of solvent. The spray should be used with caution near crop plants.

**Laboratory studies on glycerin as a supplement in water-soluble herbicidal sprays,** H. HOFF and P. J. LINDER. (U. S. D. A.). (*Amer. Jour. Bot.*, 33 (1946), No. 7, pp. 598-600, *illus. 1*).—The herbicidal effects of sodium arsenate, ammonium sulfamate, sodium trichlorophenoxyacetate, and sodium pentachlorophenoxyacetate were tested at high and low atmospheric humidity, *Coleus* and *Cuphea* being used as test plants. The results indicated that a higher water tension inside the plant from low humidity promoted the herbicidal effectiveness. At low humidity, however, the herbicides dried rapidly on the leaf surfaces, and absorption was decreased. Addition of glycerin to the solution increased the effectiveness of the herbicide at low humidity. Glycerin is believed to act by keeping the poisons in solution for absorption into the leaves over an extended time. This supplementary solvent reduced the amount of herbicide needed for killing over that required in a simple water solution.

## HORTICULTURE

**Sidedressing beets with salt gives marked returns,** J. SHAFER, JR. and C. B. SAYRE. (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 12, 13).—Following an earlier report (E. S. R., 92, p. 208) upon favorable results obtained with applications of common salt (sodium chloride) to canning beets, experiments were continued. In 1944 records were taken in three beet fields and substantial yields were obtained from salt appli-

cations. In one instance, 400 lb. of salt per acre broadcasted before planting increased the yield by 6 tons per acre. In 1945 data were obtained from 10 experimental fields, and in every case the use of 500 lb. of common salt per acre increased yields. This was true even when the yield without salt was 24 tons per acre. The salt may be applied either before planting or as a side dressing, but application is advised not later than 6 weeks after the beets are seeded if full benefits are expected. Increases were obtained even when nitrate of soda, a sodium salt, was used in the regular fertilizer.

**Carrot production in the west and southwest**, T. W. WHITAKER, J. H. MACGILLIVRAY, J. T. MIDDLETON, and W. H. LANGE. (Coop. Calif. Expt. Sta.). (*U. S. Dept. Agr. Cir. 750* (1946), pp. 32, illus. 23).—This circular presents a comprehensive picture of carrot production in the western States. Included are soil and climatic requirements, varieties, seed production, soil preparation, fertilizer needs and cultural operations, harvesting and preparation for market, and various plant disease and insect enemies and their control.

**Sweet corn suckering trials in California**, P. A. MINGES ET AL. (Calif. Sta., [n. d.], pp. 4, illus. 2).—Long-continued and widely scattered investigations conducted with irrigated sweet corn showed no significant improvement in yield, number of ears, or size of ears that could be attributed to the removal of secondary shoots. The process, commonly known as suckering, is deemed inadvisable, since it adds to cost of production with no compensating benefits.

**Progress being made in development of downy mildew resistant cucumbers** (*South Carolina Sta. Rpt. 1945*, pp. 134-138, illus. 2).—In 1939, two downy mildew resistant cucumbers, Puerto Rico 37 and Chinese Long, were crossed with a commercial variety A & C. After several generations, types were selected which combined resistance and good type. In 1943 additional crosses were made between Puerto Rico 40 and two new varieties, Cubit and Marketer.

In 1945 a serious outbreak of downy mildew occurred and destroyed the vines of all commercial varieties by June, whereas most of the resistant lines grew until plowed under in August.

The fruit type of some of the new resistant progenies approached that of Cubit and Marketer. The resistant lines produced fewer misshapen fruits in the latter part of the season than did commercial varieties, due possibly to the better retention of foliage. An increase in infection in resistant lines observed during a stormy period in September is attributed to injury and water soaking which may have been conducive to infection.

**Nutrition of the cultivated mushroom**, C. TRESCHOW (*Dansk Bot. Arkiv. 11* (1944), No. 6, pp. 180, illus. 24).—A monographic presentation considering the history of the cultivated mushroom, systematics, technics of cultivation, influences of temperature and pH on growth, mineral, carbon, and nitrogen nutrition, influences of some growth substances on growth, and experiments with mushroom cultures. Over 10 pages of references are given.

**Onion production**, D. COMIN (*New York: Orange Judd Pub. Co., 1946*, pp. 186, illus. 33).—Prepared by a member of the staff of the Ohio Experiment Station, this book contains information on types and varieties, soil and climate requirements, planting and cultural care, production of seed and sets, harvesting and curing, control of insect and disease pests, economic aspects, and uses of the onion.

**Fall production of tomatoes**, J. L. BOWERS (*Miss. Farm Res. [Mississippi Sta.], 9* (1946), No. 4, p. 8).—General information is presented on plant production, soil preparation, dipping of plants in a fungicide, planting, cultural needs, varieties, etc. Stokesdale has proved to be the outstanding variety for fall planting at State College.

**Analyses of materials sold as insecticides and fungicides during 1945,** C. S. CATHART and R. L. WILLIS (*New Jersey Stat. Insp. Ser. 20 (1945), pp. 11*).—In the usual manner (E. S. R., 94, p. 335) information is presented on the guaranteed and found analyses of various insecticides and fungicides collected during the 1945 inspection.

**Combating fruit pests in Kansas,** G. A. FLINGER (*Kansas Sta. Cir. 235 (1946), pp. 52, illus. 23*).—This revision and enlargement of Circular 199 (E. S. R., 84, p. 333) presents general information on pests and materials and methods for their control.

**Infra-red rays and smoke for frost protection to fruit crops,** C. A. DOEHLERT (*Amer. Cranberry Growers' Assoc., Proc. Ann. Conv., 76 (1945), pp. 16–17*).—A brief note suggesting that atmospheric treatment by smoke generators or with infrared rays has thus far shown little or no promise for frost protection to fruit crops.

**Color standards for McIntosh apple leaves,** O. C. COMPTON, W. C. GRANVILLE, D. BOYNTON, and E. S. PHILLIPS ([*New York Cornell Sta. Bul. 824 (1946), pp. 15, illus. 5; Sup., [p. 1]; Bul. 824A, illus. 2*]).—This bulletin, with supplementary data, presents seven color standards developed by the station for measuring the nitrogen content of McIntosh leaves during July, the month in the growing period when N content is changing the least. Directions are presented for collecting the leaf samples and for making readings from the chart.

Leaf N values below 2.1 percent in July indicate that slightly more N fertilizer should be applied at the next annual fertilization. Values above 2.1 percent suggest that less N fertilizer should be used. Limited observations indicated that a somewhat higher N level may be desirable in the Champlain Valley area than in other McIntosh sections of the State.

Records taken in a 23-year-old McIntosh orchard in Wayne County, where for the 3 yr. 1942–44 there was applied 7.5 lb. per tree of ammonium sulfate, showed a leaf N content of 2.22 percent in mid-July. Trees receiving 5.0 and 2.5 lb. of ammonium sulfate per annum had 2.06 and 1.88 percent of leaf nitrogen. On the basis of chart determinations the 5-lb. application was apparently near the optimum.

**Breeding and improvement of peach varieties in New Jersey,** M. A. BLAKE and L. J. EDGEERTON (*New Jersey Stat. Bul. 726 (1946), pp. 20, illus. 10*).—At the beginning of the present century peach growing in New Jersey was in a precarious condition; the San Jose scale had destroyed many orchards and growers were in doubt as to what varieties to plant. In recognition of the need, the station began a program of peach breeding to provide varieties upon which to establish a sound industry. The details of the breeding program are discussed, and the 32 varieties, 31 of peach and 1 nectarine, that have been named and introduced are described. These varieties cover the entire season, and so acceptable have they proved that they provide a large percentage of New Jersey peach production.

**Experimental marketing of strawberries and peaches,** C. W. HAUCK (*Ohio Sta. Bimo Bul. 240 (1946), pp. 60–64*).—In cooperation with the South Carolina and Tennessee Stations studies were made of the effect of different methods of harvesting, grading, packaging, and shipping on consumer acceptance and length of salable and usable life of peaches and strawberries. The complete enclosure of berries in quart baskets by overwrapping and heat sealing in cellophane retarded mold development and dehydration. Overwrapping with flexible transparent films encouraged purchasing by store patrons, and the condensation of moisture, although obscuring contents somewhat, was not objectionable to customers. Complete covering prevented spilling and shifting of strawberries and reduced crushing in transit and losses by pilfering. Wrapped quarts were handled easier by patrons and in general stimulated purchases.

Rigid covers prevented rounding the packages and gave the appearance of not being properly filled. Paperboard packages did not prove desirable for berries. Facing the top layers of berries added to their sales appeal.

With peaches, it was evident that tree-ripened fruits commanded a premium, with customers willing to pay a differential of as much as 5 ct. a pound. Rectangular 4 and 8 qt. paperboard baskets were used successfully for delivery of tree-ripened peaches by motor truck or refrigerated rail cars.

Overwrapping peach trays with cellophane met ready customer acceptance. Soft ripe peaches might well reach the consumer in good state if graded and packed with care and if handled under refrigeration. Prompt removal of field heat from peaches would appear necessary when handling riper fruit. Brown rot was less serious in cellophane-wrapped peaches than in open containers. Consumers preferred small packages of peaches, those weighing less than 10 lb.

**Breeding strawberries for high vitamin C content**, G. L. SLATE and W. B. ROBINSON. (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, p. 11).—Determinations of the vitamin C content of a large number of strawberry varieties showed great variability, from a high of 81 mg. of ascorbic acid per 100 grams of fruit in Catskill to a low of 41 mg. in Aberdeen. Sunlight intensity was also a factor, with fruits produced in direct sunlight having more ascorbic acid than those of same variety produced in the shade. Catskill is fortunately one of the leading market varieties in New York State.

**Summer care of dewberries**, J. P. OVERCASH (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 3, p. 8).—Cultural information is presented with relation to pruning, training, removal of fruiting canes after harvest, weeding, fertilizing, etc.

**Multiflora rose for farm hedges**, H. A. STEAVENSON. (U. S. D. A.). (*Jour. Wildlife Managt.*, 10 (1946), No. 3, pp. 227-234, illus. 1).—The need for a low cost barrier to protect farm woodland and wildlife areas against livestock became apparent early in the history of erosion-control plantings. *Rosa multiflora* has been tested as a living farm fence in the southern upper Mississippi Valley for several years and appears to be of value for these purposes and potentially even so for dividing farm fields. The discussion includes the characteristics of the plant, site and culture requirements, method of planting, barrier properties, its general and wildlife values as a living fence, and propagating and handling the planting stock.

## FORESTRY

**Radial growth of trees at different altitudes**, R. F. DAUBENMIRE. (Univ. Idaho). (*Bot. Gaz.*, 107 (1946), No. 4, pp. 462-467, illus. 5).—Radial growth changes were followed at two altitudinal levels in four forest species, *Pinus ponderosa*, *Abies grandis*, *Larix occidentalis*, and *Thuja plicata*. In all cases the trees at the low altitude on a southern slope were growing by April 19, 1942, while those at a higher altitude on a northerly slope were not growing until mid-May. The effects of dry summer weather were seen earlier at the lower altitude, and in all four species the trees at the lower stations shrank in late summer. Shrinkage in *Pinus* was so severe that full recovery to the maximum radius recorded on July 17 was not reached on October 17. Moderate shrinkage was observed in *Pinus* and *Larix* at the upper station.

In spring temperature was evidently the most apparent factor in influencing radial growth, while in summer and early autumn the water balance gradient exerted the most influence.

The time when radial enlargement is completed varies widely among the four species and is strongly affected by altitude. In general, stability is attained at

a later date at low altitudes because the hydration of tissues formed in summer is deferred until after the rainy season begins in autumn.

**37 years of windbreak planting at Akron, Colorado.** R. J. PRESTON, JR., and J. F. BRANDON. (Coop. U. S. D. A.). (*Colorado Sta. Bul.* 492 (1946), pp. 21+, illus. 10).—Beginning in 1909 a total of 29 species of trees were planted in six experiments at Akron, Colo. The most durable and effective windbreak was composed of pines, with ponderosa pine making the best record of all 29 species. After 36 yr. this pine continued to grow well and retained its vigor and health. Austrian pine was only slightly inferior to ponderosa. Rocky Mountain juniper grew vigorously and is recommended for planting along the margins of windbreaks. Eastern red cedar was less vigorous although once established it maintained itself well. Among broadleaf species hackberry and American elm were best and provided good windbreak service for 15 to 20 yr. After this time many trees died and all showed serious top injury. Siberian pea-tree and chokecherry made rapid early growth.

A good all-purpose windbreak in the area could consist of 2-6 interior rows of ponderosa pine with a marginal row on each side of Rocky Mountain juniper. A few fast-growing broadleaf species could be planted on the windward side and then removed when the evergreens had reached suitable size.

Information is provided on methods of planting, cultural care, and spacing requirements.

**The physical-mechanical properties of certain West Indian timbers, II (Las propiedades físico-mecánicas de ciertas maderas de las Indias Occidentales, II),** R. W. WELLWOOD (*U. S. Dept. Agr., Forest Serv., Caribbean Forester*, 7 (1946), No. 3, pp. 191-228, illus. 12; *Span.*, pp. 229-250; *Fr. abs.*, pp. 250-251).—Continuing this study (*E. S. R.*, 95, p. 669), data are reported as to the strength and related properties of motillo (*Sloanea berteriana*), a native Puerto Rican species with possibilities as a commercial timber; and Haitian pine (*Pinus occidentalis*), the most important timber of the island of Haiti and closely associated with slash or Cuban pine (*P. caribaea*) in structure and in physical-mechanical properties.

**The relation between curing and durability of *Bambusa tuldoidea* (Relación entre el método de curar la *Bambusa tuldoidea*),** D. G. WHITE, M. CORIN, and P. SEGUNOT ROBLES. (Coop. P. R. Fed. Expt. Sta.) (*U. S. Dept. Agr., Forest Serv., Caribbean Forester*, 7 (1946), No. 3, pp. 253-267, illus., 4; *Span.*, pp. 267-273; *Fr. abs.*, p. 273).—Cut culms of *Bambusa tuldoidea* of different ages were treated variously: (1) Clump cured for 28 days, (2) submerged in water for 130, 161, and 192 days, (3) clump cured for 14 days followed by submergence for 135 days, and (4) stored immediately in a shed (control). After treatment all culms were stored in an open shed, and observations made on powder-post beetle damage, clump curing, water submergence for 130 to 192 days, or a combination resulted in a significant reduction in insect injury. Clump curing gave equally good results as other treatments and involved less cost.

As to the effect of age of culm, those cut at 6 mo. had significantly less injury than older culms. At the same time culms of 36 and 42 mo. were injured less than those from 12 to 30 mo. old. Beetle injury was more evident in the basal than in the distal sections of culms.

The number of beetle holes which appeared in the first month of exposure was indicative of future total infestation. Even with the most effective curing treatment there was 66.7 percent of infestation, indicating that the species of bamboo used is relatively susceptible to powder-post beetle injury.

Submergence treatments stained the wood to such an extent that it could not be used where a good finish was needed. There was also considerable splitting of internodes in the submerged culms.

## DISEASES OF PLANTS

**The Plant Disease Reporter** [June 15 and July 15, 1946] (*U. S. Dept. Agr., Plant Disease Rptr.*, 30 (1946), Nos. 6, pp. 175-216, illus. 4; 7, pp. 217-263, illus. 8).—These issues contain the following notes and articles:

No. 6.—Host-parasite check list revision—*Trifolium-Trigonella* (Leguminosae), by F. Weiss; the distribution of parasitic nematodes on economic plants in Idaho, by E. C. Blodgett; the spread and development of cucurbit downy mildew in Atlantic Coastal States in 1945, by C. J. Nusbaum (S. C. Expt. Sta.); plant diseases in Palm Beach, Broward, and St. Lucie Counties, Fla., during April, by G. R. Townsend, R. C. Cassell, E. L. Felix, and R. Desrosiers (Fla. Everglades Sta.); greenhouse vegetable diseases of interest in New York, by A. G. Newhall (Cornell Univ.); preliminary experiment indicates that 2, 4-D (2, 4-dichlorophenoxyacetic acid) treatment of tomato may reduce losses due to fruit crack molds, by W. T. Schroeder and F. G. Smith (N. Y. State Sta.); seed protectants on sweet corn in relation to plant vigor, by B. H. Davis and C. M. Haenseler (N. J. Stas.); reports on tobacco blue mold in South Carolina, Kentucky (Ky. Sta.), and Maryland (Univ. Md.); peach wart found in California, by G. L. Stout and R. L. McClain; sour cherries in Virginia killed as a result of 1945 leaf spot epiphytotic, by A. B. Groves (Va. Sta.); spread of white pine blister rust during 1945, by J. F. Martin; dieback and stem canker of camellia, by D. C. Bain (Miss. Sta.); a disease of English ivy in Georgia, by K. H. Garren (Ga. Sta.); an epiphytotic of verticillium wilt in southern California, by K. F. Baker and W. F. Locke (Univ. Calif.); and brief notes on sweetpotato internal cork in Georgia (Univ. Ga.), a field test of late blight resistance in tomatoes, and germination of tobacco seed prevented by cyanamid (Ky. Sta.).

No. 7.—Host-parasite check list revision—*Vicia-Vigna* (Leguminosae), by F. Weiss; zoospore development from oospores of *Pythium ultimum* and *P. debaryanum* and its relation to rootlet-tip discoloration, by C. Drechsler; tobacco blue mold in Georgia, by J. G. Gaines; blue mold in Kentucky in 1946, by W. D. Vallean and E. M. Johnson (Ky. Sta.); late blight as reported on potato and tomato in Maryland (Univ. Md.), Pennsylvania (Pa. State Col.), and Georgia (Univ. Ga.); occurrence of corky ringspot of potatoes in Florida, by A. H. Eddins, E. Q. Procter, and E. West (Fla. Sta.); fumes from 2-4-D cause injury to tomato, cabbage, and pepper plants, by E. M. Johnson and P. O. Ritcher (Ky. Sta.); plant disease survey in the Everglades and contiguous areas during the 1945-46 season, by G. R. Townsend, R. C. Cassell, E. L. Felix, and R. Desrosiers (Fla. Everglades Sta.); alfalfa and clover diseases in Virginia, by S. B. Fenhe, C. L. Lefebvre, R. G. Henderson, and T. J. Smith (Va. Polytech. Inst.); rusts of small grains in Texas, by I. M. Atkins; azalea flower spot appears in Maryland, by P. Brierley; observations on azalea flower spot in Maryland, by F. Weiss; brief notes on lettuce rust in New York (Cornell Univ.) and sour cherry yellows in North Carolina (N. C. Sta.); observations on coffee root rot in El Salvador, by F. L. Wellman; and the loss from cotton wilt and the tempo of wilt development—a study of new uses for old data, including discussion and graphical presentation of the data and planning of future cooperative programs, by K. S. Chester (Okla. A. and M. Col.).

**The Plant Disease Reporter, Index to Volume XXVIII, 1944**, N. W. NANCE (*U. S. Dept. Agr., Plant Disease Rptr.*, 28 (1946). No. 40, pp. 1191-1266).

**Report of the 1946 annual meeting of the New England Division of the American Phytopathological Society** (*Phytopathology*, 36 (1946), No. 8, pp. 679-683).—Abstracts of 14 papers by various authors—including experiment station and U. S. Department of Agriculture workers—are presented on the following subjects: *Alternaria solani* defoliation of New Hampshire Victor tomatoes as

influenced by inorganic fertilizers, fungicidal control of alternaria blight on tomatoes, fungicidal stimulation and retardation of germination in vegetable seeds, damping-off control by delayed watering after seeding, Dutch elm disease studies in Massachusetts, soil applications of oxyquinolin benzoate against foliage wilting in graphium-infected elms, spray penetration v. apple leaf structure, common scab incidence on Green Mountain potatoes v. pH of soil, tobacco pole-rot fungi, permeation v. toxicity of fungicides, concentration, pressure, time, and orifice interactions in spraying, stability assay of organic fungicide residues, and glyoxalidine derivatives as foliage fungicides studied in laboratory and field.

**Report of the third annual meeting of the Potomac Division of the American Phytopathological Society** (*Phytopathology*, 36 (1946), No. 8, pp. 684-689).—Abstracts of 24 papers by various authors—including State experiment station and U. S. Department of Agriculture workers—are presented on the following subjects: Effects of fungicides and growth substances on field production of Easter lily bulbs, effects of fungicide-growth-substance combinations on herbaceous cuttings, possible growth-regulating effects of several fungicides, factorial studies on Dithane plus zinc sulfate-lime—the “reaction product” (zinc ethylene bisdithiocarbamate), seed treatment of castor-beans against seedling blight, seed treatment effects on soybeans germinated at four temperatures, apparatus and field plot design for evaluating fungicides on vegetables, field control of bean rust with sulfur, *Lycopersicon hirsutum* lines resistant to common tobacco mosaic, field occurrence of a tobacco etch virus strain in sweet peppers, tobacco resistant to root knot and nematode root rot, tobacco blue mold control by aerosol treatments, barley seed inoculation method for *Helminthosporium gramineum*, status of disease-resistance breeding in oats, golden nematode as a quarantine problem, golden nematode as a disease agent (distribution, hosts, character, and significance), soil fumigation against golden nematode, golden nematode on commercial potatoes, nature of net necrosis of potato (leafhopper injury?), progress on tropical American rubber planting through disease control, regional differences in resistance of *Hevea* selections to South American leaf blight, Dutch elm disease spread in Maryland, rate of spread of blueberry stunt in a North Carolina field, and yellows-type strawberry virus in eastern United States.

[Papers on plant diseases and their control] (*Ohio Veg. and Potato Growers Assoc. Proc.*, 29 (1944), pp. 49-58, 80-90, 97-109, 138-152).—The following papers are included: Spray and Dust Formulas for the Control of Vegetable Diseases in Ohio, by J. D. Wilson (pp. 49-58), and Spray Intervals and Potato Yields, by H. L. Gui, J. P. Sleesman, and J. D. Wilson (pp. 104-109) (both Ohio Expt. Sta.); Virus Diseases Affecting Vegetable Crops in the Field (pp. 80-90) and The Virus Diseases Affecting Tomatoes and Cucumbers in the Greenhouse (pp. 138-152), both by S. P. Doolittle (U. S. D. A.); and Soil Fumigation in Greenhouses and Outdoor Seed Beds With Chlorpicrin and Other Promising Materials, by J. M. Bickerton (pp. 97-103).

**Virus diseases of plants and their insect vectors with special reference to Hawaii**, D. D. JENSEN. (Hawaii Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 12 (1946), No. 3, pp. 535-610).—The subject matter of this monographic contribution is presented under (1) the principles of insect transmission of plant viruses, (2) insect species in Hawaii known to transmit plant viruses with a list of viruses transmitted by each, and (3) plant virus diseases known or reported to occur in Hawaii with special reference to their insect transmission. A review of the literature (251 references) reveals that although a considerable number of plant viruses occur in Hawaii, most of them have received only passing notice. Those most extensively investigated are yellow spot of pineapple (spotted wilt of tomato), sugarcane mosaic and chlorotic streak, corn mosaic, and to a lesser

extent papaya and commelina mosaics. Other viruses occur in truck crops, banana, ornamental flowers, and weed hosts. The increasing importance assumed by diversified crops in Hawaii has resulted in a greater awareness by entomologists and pathologists of the importance of virus diseases on these various crop plants; furthermore the number and importance of the associated problems usually increase as the acreage devoted to economic plants is enlarged.

**A physiological and biochemical basis for research on fungicides**, D. GOTTLIEB. (Univ. Ill.). (*Bul. Torrey Bot. Club*, 73 (1946), No. 4, pp. 339-345).—In this general critical discussion, the emphasis on fundamental studies of the physiology and biochemistry of the fungi as an aid to fungicide development is not proposed as an alternative method to empirical research; rather, it is suggested as a guide for such investigations into areas of biochemical reactions concerned with the vital processes of the fungus and where the empirical methods could be most effectively employed. In addition, fundamental studies of the living organism can furnish clues to the type of organic molecule which effectively inhibits the biochemical reactions necessary to the life of the organism. Finally, such research can put plant protection on a basis of rational scientific principles. There are 21 references.

**Trials with zinc-bearing dusts**, J. C. JOHNSTON. (Univ. Calif.). (*Calif. Citrog.*, 31 (1946), No. 10, pp. 406-407).—In the series of field trials (1934-35) reported, the dusts were, in general, not as effective as sprays in citrus mottle leaf control, though in a 1934 test "for practical purposes adequate control was secured with the 4 percent dusts where the zinc was derived from zinc sulfate, zinc oxide, and metallic zinc."

**Effect of hydrogen-ion concentration on the toxicity to *Colletotrichum circinans* (Berk.) Vogl. of some carboxylic acids, phenols, and crucifer extracts**, F. G. SMITH, J. C. WALKER, and W. J. HOOKER. (Univ. Wis.). (*Amer. Jour. Bot.*, 33 (1946), No. 5, pp. 351-356, illus. 3).—The authors observed the toxicity of ether-soluble strong acid fractions of crucifer extracts to be correlated with pH. A study of the variation in toxicity with the pH of extracts and several typical phenols and carboxylic acids was then made by determining the percentage of spore germination. Plotting logarithms of LD50 values against pH gave characteristic curves for each group of toxicants. The carboxylic acids exhibited nearly parallel linear curves with toxicity decreasing in the order, benzoic, protocatechic, and acetic acids. Calculated pH-LD50 curves for the undissociated acid fraction did not altogether support the hypothesis that this molecular species is responsible for the toxicity of carboxylic acids at various H-ion concentrations. Hydroquinone and catechol showed distinctly different curves than the acids. The marked increase in toxicity at pH 7, especially with the former, and comparison with the toxicity of the corresponding *p*-quinone suggested that autoxidation to quinone had taken place. The curves for crucifer extracts indicated carboxylic acids or similar toxicants to be largely responsible for toxicity. These findings suggest two possible mechanisms by which relatively small differences in pH may produce changes in fungicidal activity of importance in natural disease resistance or in the application of commercial fungicides. There are 31 references.

**Rootrots and leafspots of grains and grasses in the northern Great Plains and Western States**, R. SPRAGUE. (Coop. N. Dak. Expt. Sta.). (*U. S. Dept. Agr., Plant Disease Rptr.*, 1946, Sup. 163, pp. 101-268).—This annotated list contains at least mention of all the parasites known by the author to attack the grass family in the western United States and includes some 200 fungus species on nearly 500 hosts. Though this preliminary work is not considered a text, it is somewhat more than a list and the author believes that it may have some value

to a number of western experiment station workers and field men in the routine diagnosis and study of the lesser-known leaf spot and root rot diseases of grasses and cereals. Since brevity was necessary, it was felt that some of the better-known parasites should be given less space than some of the little-known ones, as information on the latter is frequently buried in obscure journals. Included are 13 Phycomycetes, 24 Ascomycetes (if 15 species of *Phyllachora* are admitted), 8 Basidiomycetes, and 162 Fungi Imperfecti, as well as a few undetermined or nonparasitic troubles. In addition, brief mention is made of associated non-parasitic saprophytes which are sometimes such early invaders of dead tissue that they have in some cases been considered weakly parasitic. A table indicates the number of species of leaf spot and root rot fungi reported on Gramineae in each of 17 Western States.

**Distinguishing characteristics of some forage-grass diseases prevalent in the North Central States, J. L. ALLISON and D. W. CHAMBERLAIN.** (Coop. Wis. Expt. Sta.). (U. S. Dept. Agr. Cir. 747 (1946), pp. 16, illus. 16).—This circular brings together available information on the more important diseases of pasture and forage grasses in the above region, emphasis being placed on the distinguishing characteristics of each disease but without attempting to include all hosts or all diseases known to occur in the area. The development of resistant strains offers the only practical control measure; resistance to many of the diseases reviewed has been demonstrated. The presence of physiological races in certain of the fungi discussed has been recognized. Improvement programs are in progress with all the major grass species here considered.

**Effect of soil temperature on the development of rhizoctonia root canker of alfalfa, O. F. SMITH.** (Nev. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 36 (1946), No. 8, pp. 638-642, illus. 3).—The optimum temperatures for growth of *Rhizoctonia solani* on potato-dextrose agar, as well as the soil temperature for development of the root canker on alfalfa, proved to be about 25°-30° C. Very few cankers developed within 50 days below 20° or above 35°. In the field, very few root cankers developed before the soil had warmed to 20° or higher in spring, and they ceased to develop in the fall after the soil cooled to about 20° or below.

**Temporary immunity in alfalfa ordinarily susceptible to attack by the pea aphid, W. T. EMERY.** (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 73 (1946), No. 2, pp. 33-43, illus. 5).—Alfalfa plants that are highly susceptible to the pea aphid in some seasons do not support an aphid population in other seasons. Results show that temporary immunity to their feeding is associated with an acid condition in the plant and that this acidity may be caused by (1) a deficiency of water, (2) a deficiency of light for photosynthesis, (3) temperatures too low for rapid growth of alfalfa, and (4) temperatures sufficiently high to cause the formation of lignin. Measurements of the cell sap for osazones have shown that aphids feed most on the elongating internodes, where growth is rapid and where sucrose is most abundant. Since the synthesis of protein is dependent on a "carbohydrate-nitrogen ratio," it is thought that resistance in alfalfa to the pea aphid is correlated primarily with an acid condition and a scarcity or absence of sucrose rather than with a scarcity of proteins in the plants.

**What's the matter with our barley? K. S. QUISENBERRY and O. J. WEBSTER.** (U. S. D. A. coop. Nebr. Expt. Sta.). (*Nebr. State Bd. Agr. Ann. Rpt.*, 1945, pp. 204-214, illus. 3).—The authors present evidence showing that during the last 25 yr. barley production in Nebraska has fluctuated rather widely; during the past 5 yr., the performance was very poor as compared with some earlier years or with the production of oats. Poor yields have been due to a number of causes, such as unfavorable weather, disease and insect injuries, and lack of hazard.

resistance in the adapted varieties. To increase the chances of success with barley, farmers are advised to obtain certified seed of recommended varieties and to treat it with the proper fungicidal dusts. The crop should be seeded as early in spring as possible and on a well-prepared seedbed. Barley should not follow corn, wheat, or barley in the rotation if these crops have shown scab the previous year unless all crop refuse is well covered. Where heavy infestations of chinch bugs are expected, barley should not be seeded at all. Winter barley is considered somewhat of a risk because of its lack of winter hardiness; of the available varieties, Reno and Ward are considered the best.

**Association of *Xanthomonas phaseoli* and the common bean-mosaic virus, Marmor phaseoli, II, III.** (U. S. D. A.). (*Phytopathology*, 36 (1946), No. 8, pp. 589-623, *illus.* 7).—Two additional papers (E. S. R. 91, p. 698) are presented:

II. *Dissociation studies of X. phaseoli*, F. Hedges (pp. 589-612).—The author studied dissociation in an isolate of *X. phaseoli* (P(M+P)<sup>43</sup>) from a badly stunted plant of the thirty-fourth serial passage from bean to bean plants of juice containing the two infective agents *X. phaseoli* and the virus of common bean mosaic. This serial passage had shortly preceded (1) one in which all bacterial symptoms disappeared from the inoculated plants and (2) the sudden onset of ultra-severe mosaic which followed in the thirty-eighth serial passage<sup>1</sup> and persisted in those ensuing. Parallel studies were also made of a "normal"<sup>1</sup> strain of *X. phaseoli*, with no history of mosaic virus association, isolated from a lima bean pod. The investigation was undertaken to show whether changes had taken place in the bacterium during its 2-yr. association with the virus in vivo which might account for its decreased virulence and failure to maintain continuously its "typical" form in the host tissues as earlier described. A. J. Quirk's technic of dissociation was employed.

Dissociated cultures of the two strains showed striking differences between P(M+P)<sup>43</sup> and the normal strain of *X. phaseoli*. In the former the mildly infectious R-S opaque white and the nonpathogenic S pink variants developed at the expense of the typical virulent S yellow form. In the dissociated normal strain, on the other hand, the virulent S yellow form dominated markedly. The dissociation phenomenon and the difference between the two strains were far better demonstrated on Quirk's media II, III, and IV than on the media<sup>1</sup> commonly used for phytopathogenic bacteria. Inoculation tests with various dissociated cultures of the two strains revealed that when the R-S white variant<sup>1</sup> was dominant infection was poor or only fair, the degree of pathogenicity being directly proportional to the amount of the typical S yellow form of *X. phaseoli* in the inoculum.

III. *The effect of varying amounts of nitrogen on pathogenicity*, F. Hedges and H. Fisher (pp. 613-623).—The effects of varying amounts of N—9.8, 200, and 2,000 p. p. m.—were tested on sand cultures of Stringless Green Refugee bean seedlings inoculated with (1) juice from serial passages from bean to bean plants of expressed bean juice containing *X. phaseoli* and common bean mosaic virus, (2) pure single-colony cultures of *X. phaseoli*, and (3) juice<sup>1</sup> from serial passages of bean juice containing common bean mosaic virus. These serial passages had been carried on over a period of years and described in an earlier paper by Hedges. The best development of both virus and bacterium in all sets was induced by the medium concentration of N (200 p. p. m.);<sup>1</sup> this was also optimum for the host. Pathogenicity tests were made of expressed<sup>1</sup> juice from plants in which the two infective agents were associated. The results indicated that the virus had not been permanently inhibited by any of the three N concentrations; on the other hand, N at both 9.8 and 2,000 p. p. m.

had markedly inhibited the bacterium. However, when isolates of the bacterium from the same three N sets were first grown in a favorable medium (steamed potato cylinders) and then used as inoculum, all were highly virulent, though the isolate from the medium N concentration (200 p. p. m.) was notably more so.

**Helminthosporium turcicum leaf blight of corn**, C. ELLIOTT and M. T. JENKINS. (U. S. D. A.). (*Phytopathology*, 36 (1946), No. 8, pp. 660-666, illus. 2).—In field inoculation tests of corn with *H. turcicum* at Beltsville, Md. (1944), most of the inbred lines and crosses proved susceptible but a few lines were resistant; the earlier maturing lines and crosses were, in general, more susceptible than later lines and crosses; NC34 was outstanding in its resistance and in transmitting resistance to its crosses; CI23, K175, Ky114, Mo21A, T40B, T105B, K155, CI15, CI16, and Tx206 had only traces to light infection; the other lines showed moderate to very heavy infection. In general, the resistance of resistant lines was transmitted to their hybrids.

**A new seed-borne disease of oats**, W. F. CROSBIE. (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, p. 5).—The Vicland variety of oats was found especially susceptible to a new fungus blight and root rot caused by *Helminthosporium* sp. with all seed stocks tested at Geneva showing infection. Desirable new varieties such as Boone, Cedar, Fultex, Letoria, and Neosho—though free from crown rust—proved extremely susceptible to the new disease; strong indications were that resistance to rust is linked with susceptibility to the *Helminthosporium*. Fortunately some of the older varieties of oats (Cornellian, Ithacan, and Lenroc) have not been attacked. Almost complete control of this seed-borne blight was obtained by seed treatment with a volatile mercury dust—either new Improved Ceresan or duPont 1452F.

**Late blight on potato and tomato in 1946** (U. S. Dept. Agr., *Plant Disease Rptr.*, 1946, Sup. 164, pp. 269-296, illus. 5).—Reports that *Phytophthora infestans* infection was appearing to an alarming extent were received from several commercial tomato-growing areas. With the aim of presenting a systematic and timely account of the development of the disease in 1946 on its two important hosts, the Plant Disease Survey asked its collaborators in States where late blight is likely to occur to send reports of its incidence on potato and tomato (either or both), especially as to the following points: "Has the disease occurred on either host and to what extent? What control measures, if any, have been taken? When was the disease first noted, and what in your opinion was the original source of infection?" The answers to these questions—except for a few negative replies—are presented here. Together with reports from various Florida sections that have appeared in each number of the *Reporter* from December 1945 to the current issue, they give a rather complete story of the occurrence of the disease to about the middle of June 1946.

Some of the factors brought out in the reports may be briefly indicated: Weather was unusually favorable for late blight development over a long period of time and over a widespread area; the disease is reported as appearing much earlier in several States in 1946 than previously; the reports from State pathologists and collaborators as to original sources of infection raise an interesting question of reciprocal responsibility, which is discussed.

**Green dwarf: A virus disease of potato**, J. A. MILBRATH. (Oreg. Expt. Sta.). (*Phytopathology*, 36 (1946), No. 8, pp. 671-674, illus. 2).—A previously undescribed tuber-transmitted virus disease of potatoes, called green dwarf, is reported from several counties in Oregon. The outstanding symptoms are late emergence and extreme dwarfing. The basal leaves appear normal, but are close together in a rosette of four to five leaves. The terminal growth is dwarfed and

malformed, and the growing point is pinched together in a cluster of small leaves. The leaflets on the young leaves cup upward, forming small boatlike structures. The infection was transmitted by grafting stems of affected Netted Gem potatoes to healthy Netted Gem, White Rose, Burbank, Green Mountain, and virus X-immune seedlings.

**Resistance of potato seedling varieties to the natural spread of leaf roll.** D. FOLSOM and F. J. STEVENSON. (Maine Expt. Sta. and U. S. D. A.) (*Amer. Potato Jour.*, 23 (1946), No. 7, pp. 247-264).—Seedling potatoes were exposed to leaf roll infection from adjacent field rows in an area where the disease had spread consistently year after year. The parents at first used included commercial American and European varieties reputed to be resistant to this virus; a few of the crosses employed also contained some seedlings resistant to the spontaneous spread of leaf roll. When the latter were used as parents, the resulting crosses were usually more resistant to field spread than other kinds of crosses. Greater resistance in one of the parents did not always mean resistance in the cross. Furthermore, higher resistance in a cross (judged by percentage of seedlings showing leaf roll) was not necessarily correlated with the percentage of total plants exhibiting the disease in the infected seedlings. Field resistance in given seedlings and varieties differed from one season to another on the same farm. Although aphids are probably important in the field spread of leaf roll, aphid resistance in seedlings is not necessary for field resistance to infection. It is possible to combine field resistance to leaf roll with many characteristics considered commercially desirable in the United States. There are 31 references.

**Golden nematode of potatoes jumps the Atlantic.** A. G. NEWHALL. ([N. Y.] Cornell Expt. Sta.) (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 6, 7, illus. 1).—This contribution indicates that the golden nematode—never before found in America—probably appeared in Nassau County, Long Island, about 1930; by 1941 nearly all of a 50-acre field was badly infested. Insofar as known, this serious potato disease is confined to that county; intensive research is under way to find effective control measures, and every precaution is being taken to prevent its further spread. The symptoms of infestation are briefly described.

**Grain storage studies.**—III, The relation between moisture content, mold growth, and respiration of soybeans, M. MILNER and W. F. GEDDES. (Minn. Expt. Sta.). (*Cereal Chem.*, 23 (1946), No. 3, pp. 225-247, illus. 4).—In this contribution (E. S. R. 94, p. 464), the influence of moisture content on the respiratory characteristics of soybeans of varying commercial quality at 37.8° C. was studied by a technic providing for simultaneous measurement of O<sub>2</sub> consumption and CO<sub>2</sub> production under continuous and controlled aeration for periods up to 15 days. Moisture below about 14 percent yielded very low but virtually constant respiratory rates over extended periods, indicative of seed respiration only. Small moisture increments beyond this were accompanied by respiratory increases for several days until equilibrium was approached; this effect was due to mold growth, the plotted respiration values thus assuming the form of a microbiological growth curve. The latent period of mold spore germination decreased with increasing moisture. Frost-damaged seeds gave shorter respiratory lag periods and considerably higher respiration rates than normal seeds, as well as lower critical moisture values. These differences are ascribed primarily to the greater concentration and ready availability of nutrients for mold growth in damaged than in sound seeds.

The respiratory characteristics of autoclave-sterilized soybeans at various moisture levels, inoculated with spores of molds indigenous to normal soybeans, exhibited the same characteristic sharp upward trend in respiration at a critical

value as did normal seeds; the low respiration values of normal seeds at lower moisture levels (seed respiration) were absent. Wetting or heating of normal soybeans caused an initial evolution of CO<sub>2</sub>, apparently not related to respiration; this was attributed to the release of preformed CO<sub>2</sub>, bound by the dormant seeds. Respiratory quotients increased with the moisture content and approached 1.0 as the ratio of mold- to seed-respiration increased. When seed respiration was absent (autoclaved mold-inoculated seeds), the respiratory quotient of 1.0 exhibited by the mold respiration was unaffected by moisture content. The viability of soybeans decreased somewhat when the seeds were held at 37.8° at moisture levels below those favoring mold growth, but were most adversely affected at moisture contents where molds grew readily. Only slight changes with time in the chemical composition of respiring soybeans were noted at moisture values unfavorable to mold growth; at those where molds proliferated, drastic chemical changes occurred and were approximately proportional to the moisture content and extent of mold growth. Significant increases in the moisture content of soybeans maintained in atmospheres of constant humidity in equilibrium with the seed moisture were observed when mold growth was extensive. At the same relative humidity, mold mycelia are probably more hygroscopic than are soybeans.

*Aspergillus glaucus* and *A. flavus* were the principal fungi proliferating on soybeans within the moisture range studied; the latter required a moisture value some 3 percent higher for germination. The literature reviewed (about two pages of references) indicated that a few mold types can germinate and grow at relative humidities as low as 75 percent; an increasing diversity of microfloral species appears at higher humidities. Relative humidity rather than the actual moisture content of seeds determines their susceptibility to molding. It is concluded that the various "critical" moisture values for different seed species are those which are in hygroscopic equilibrium with a common relative humidity of about 75 percent which, over moderate time intervals, is the minimum humidity required for growth of most of the xerophytic mold species contaminating the seeds.

**Yellow wilt of sugar beet in Argentina.** C. W. BENNETT and C. MUNCK. (U. S. D. A. et al.). (*Jour. Agr. Res. [U. S.]*, 73 (1946), No. 2, pp. 45-64, illus. 8). —A disease, given the suggested name "yellow wilt," has caused severe damage to sugar beets in the Río Negro Valley, probably since the industry was first established there in 1929. One phase is characterized by stunting, yellowing of the foliage, slight stimulation of development of axillary buds, and leaf malformation: wilting and rapid killing of plants are characteristic of another phase. Plants are usually attacked after attaining considerable size. In the greenhouse, the disease was transmitted by grafting to healthy tissue and by each of two species of dodder (*Cuscuta subinclusa* and *C. campestris*), but not by juice inoculation. Field observations indicated a leafhopper (*Atanus exitiosus* Beamer) to be the vector. The evidence indicates that yellow wilt is caused by a previously unknown virus, for which the designations *Chlorogenus patagoniensis* n. sp. and Beta virus 6 are proposed in accordance with the systems of classification and nomenclature of Holmes and of Smith, respectively. In extensive tests in two seasons, involving 20 European varieties and 2 varieties from the United States the first season and 28 European varieties and 2 varieties from the United States the second season, no evidence was obtained of an appreciable amount of resistance in any variety of sugar beet. Satisfactory control measures for the disease have not been developed. Plantings made after the middle of December escape infection in the Río Negro Valley, but this date of planting is too late for maximum yields. Selection and propagation of healthy beets from badly infested

fields have not resulted in increased resistance in the progeny. Other possible methods of control have not been tested.

**Stem distortion of wheat**, E. C. BLODGETT and H. K. SCHULTZ. (Idaho Expt. Sta.) (*Jour. Amer. Soc. Agron.*, 38 (1946), No. 8, pp. 717-722, illus. 2).—A characteristic type of stem distortion in wheat was found perpetuated from season to season by the seed of winter wheat. Although the possibility that insects or parasitic organisms are involved is not definitely precluded, the indications are that the condition may be caused by some genetic factor or by a virus. There is some resemblance between the symptoms of stem distortion and those due to injury by the western wheat aphid. Although certain facts have been established, it is desirable to study the condition further.

**Experiments on the overwintering in the soil of bacteria causing leaf and pod spots of snap and lima beans**, F. HEDGES. (U. S. D. A.). (*Phytopathology*, 36 (1946), No. 8, pp. 677-678).—The soil hold-over of *Pseudomonas medicaginis phaseolicola*, *Xanthomonas phaseoli*, and *P. syringae* was tested by growing susceptible varieties of snap and lima beans in soil where leaves, pods, and stems of plants severely infected with one or more of these organisms had been buried the preceding fall. The results of all these field experiments—carried out on the Eastern Shore of Maryland and in Virginia—were negative. Soil in which lima bean leaves infected with *P. medicaginis phaseolicola* had been buried in October failed to produce infection when dusted on pricked and sprayed lima bean plants in damp chambers the following June. When lima bean leaves infected with *P. syringae* and exposed to weathering without contact with the soil from October until June were used as inoculum, being crushed to powder and dusted on sprayed and pricked lima bean seedlings in damp chambers, no infection resulted.

**Fermate does control cucumber anthracnose**, F. J. LEBEAU. (La. Expt. Sta.). (*Food Packer*, 27 (1946), No. 8, pp. 67-68, illus. 3).—In the 2 years' tests reported, a 10-percent Fermate dust is said to have given practically 100 percent control and without apparent injury to the plants; bordeaux and yellow Cuproicide caused considerable damage, so that frequently the gain from disease control was overbalanced by the injury. In tests with other plants, Fermate has also been outstanding against anthracnose, suggesting that it may prove highly specific for this class of disease.

**Apple scab and its control**, A. B. BURRELL. (Cornell Univ.). (*Amer. Fruit Grower*, 66 (1946), No. 1, pp. 10-11, 30, 39-41, 49, illus. 6).—A general summary of present knowledge on this disease and its control, with seasonal notes and experimental data from New York State.

**Machinery for applying scab control sprays and dusts**, A. B. BURRELL. (Cornell Univ.). (*Amer. Fruit Grower*, 66 (1946), No. 2, pp. 18-19, 37-39, 43, 45, illus. 7).—A general discussion of the different types of machinery used in apple scab control, including attachments to standard spray equipment, newer kinds of sprayers, small- and large-volume machines, the more rapid application of dusts as compared with sprays, and labor costs.

**Transmission of peach wart by graft inoculations with affected fruit tissue**, E. C. BLODGETT. (Idaho Expt. Sta.) (*Phytopathology*, 36 (1946), No. 8, p. 675).—Three J. H. Hale and three Elberta peach trees in plots at Moscow, Idaho, were inoculated in August 1942 with wedges of warty fruit tissue; examination in 1945 showed that the virus had in every case been transmitted. The fruit tissue wedges—held in place in T-shaped cuts in the trunk by rubber bands—remained green and apparently alive for at least a month. Trees not inoculated with peach wart either by buds or fruit tissue failed to become affected. This technique offers a useful means for studying the peach wart virus.

**Control of leaf curl and "pockets" of the sand cherry, W. F. BUCHHOLZ.** (S. Dak. Expt. Sta.) (*S. Dak. State Hort. Soc. Ann. Rpt.*, 42 (1945), pp. 37-38).—The results of a 3-yr. series of tests show that the taphrina leaf curl and pockets of sand cherries can be controlled by a dormant spray with lime-sulfur (1-10) applied in the fall or early spring; whether or not the same will apply to plum pockets remains to be determined.

**Ten additional leafhopper vectors of the virus causing Pierce's disease of grapes, N. W. FRAZIER and J. H. FREITAG.** (Calif. Expt. Sta.). (*Phytopathology*, 36 (1946), No. 8, pp. 634-637).—The following leafhoppers are shown to be vectors of the virus of Pierce's disease of grapes: *Carneocephala triguttata* Nott., *Neokolla gothica* (Sign.), *N. confluens* (Uhler), *N. heiroglyphica* (Say), *Cuernia occidentalis* Oman & Beamer, *Pagaronia triunata* Ball, *P. 13-punctata* Ball, *P. furcata* Oman, *P. confusa* Oman, and *Friscanus friscanus* (Ball). None appeared to be important in the spread of the virus to alfalfa or grape in the field. All 10 species are in the leafhopper subfamily Tettigoniellinae, as are 4 previously reported vectors; all members of the group thus far tested have transmitted the virus. Over 50 species of leafhoppers in other subfamilies were tested, but none spread the infection. The evidence at hand suggests that the ability to transmit the virus can be correlated with a phylogenetic relationship of vectors within the Tettigoniellinae.

**Control of chlorosis in citrus leaves, A. R. C. HAAS and G. A. ZENTMYER.** (Calif. Citrus Expt. Sta.) (*Calif. Citrog.*, 31 (1946), No. 9, pp. 334-335, 346-348, illus. 4).—Numerous attempts have been made to control chlorosis, as, e. g., by soil, trunk, branch, or leaf treatments; none of these methods have been fully satisfactory and many have proved injurious to the trees. Much of the difficulty from inorganic Fe compounds has resulted from their acidity, rapid precipitation, or relative insolubility. Use of the organic fungicide, Fermate, as a dust or spray was found of value as a source of Fe in controlling chlorosis; a uniform deposit of active Fe over the leaf and axils of the petioles is essential. Adjustment of water to about pH 5 for spraying and addition of S in amounts insufficient to cause burning aided in maintaining the Fe solubility of the spray deposit; the S is also useful in dust applications. A suitable spreader or sticker may serve to establish and maintain contact of the Fe particles with the leaf surfaces. Magnetite was likewise used and found to offer control. Very chlorotic orange leaves exhibited considerable uniform improvement 11 days after dusting with Fermate or magnetite—both with the added S. Use of acid fertilizers, control of soil moisture, encouragement of shallow rooting, and recognition that all alkaline calcareous soils are potentially capable of inducing chlorosis should aid in its prevention. Laboratory tests with Fe sources quite different from those previously used offer considerable promise. Maintaining the Fe applied to the leaves in an available form via acidifying rather than alkalizing agents should increase the effectiveness of control measures.

**Stubborn disease of citrus, a virosis, H. S. FAWCETT.** (Calif. Citrus Expt. Sta.) (*Phytopathology*, 36 (1946), No. 8, pp. 675-677).—This malady of navel orange trees was shown by transmission tests to be of a virus origin. The symptoms consist of a brushlike growth of twigs developing from multiple buds, leaves broader and shorter than normal and becoming chlorotic in the fall and winter, and fruits fewer in number and some of them acorn-shaped, on which the rind at the stem end is normal but becoming abruptly thinner and smoother over the rest of the surface. The virus is named on the basis of symptoms produced and described for the first time as *Citriovir pertinaciae*.

**Diseases of the walnut in the Pacific Northwest and their control, P. W. MILLER, C. E. SCHUSTER, and R. E. STEPHENSON.** (Coop. U. S. D. A.). (*Oregon Sta.*

*Bul. 435 (1945), pp. 42, illus. 29*).—The Persian (English) walnut (*Juglans regia*) in the Pacific Northwest is attacked by a number of diseases that adversely affect the growth of the trees and the quality and yield of the nuts. It is the purpose of this bulletin to provide the grower with information that will enable him to recognize these diseases and to employ against them effective control measures where known.

**Dieback of camellia**, D. C. BAIN (*Miss. Farm Res. [Mississippi Sta.], 9 (1946), No. 4, pp. 2, 5*).—The author describes a dieback of camellia which for several years has been prevalent in Mississippi and other States—particularly in nurseries along the Gulf coast. There are strong indications that the dieback later develops into a canker. Bits of material from both forms were cultured and the same fungus—a *Gloeosporium*—was isolated from each; furthermore, inoculations from the pure cultures have produced the dieback symptoms. Spray tests against the disease are being carried out, and some indications of resistant varieties have been observed.

**Decay following glaze storm damage in woodlands of central New York**, P. SPAULDING and A. W. BRATTON. (U. S. D. A.). (*Jour. Forestry, 44 (1946), No. 7, pp. 515-519, illus. 3*).—Northern hardwood stands in Otsego and Herkimer Counties were severely damaged by an ice storm in December 1942. Early in 1945 sap rot had developed at the bases of injured but living sugar maple and beech trees. The initial injury was apparently due to sunscald caused by sudden opening of the stands. The silvicultural significance of the sap-rot fungi attacking injured trees is indicated. *Daedalea unicolor* was found fruiting on nearly every sap-rotted tree and evidently was one of the first fungi to attack them. Other fungi of the so-called sap-rot-producing species were *Peniophora* sp., *Polyporus adustus*, *P. hirsutus*, *P. pargamensis*, *P. tulipiferus*, *P. versicolor*, and *Schizophyllum commune*; further research may reveal others, but these were the common ones found.

**Fusarium disease of prickly pear**, C. W. CARPENTER. (Hawaii. Sugar Planters' Expt. Sta.). (*Cactus and Succulent Jour., 17 (1945), No. 12, p. 169*).—Promising results in pricklypear eradication are briefly noted.

## ECONOMIC ZOOLOGY—ENTOMOLOGY

**Geographic distribution of Texas wildlife**, W. P. TAYLOR. (Tex. A. and M. Col. et al.). (*Tex. Geog. Mag., 9 (1945), No. 1, pp. 1-12, illus. 7*).—The author discusses the diversity of Texas habitats, geography in relation to species, some geographic relations of Texas wildlife, ecologic types as indicated by mammals (including lists of mammals generally distributed in the State or in three or more of its main divisions, principally in west and east Texas, respectively, and those occurring mainly in the plains country, in the Rio Grande plain, and in the Trans-Pecos), geography and vanishing forms of wildlife, and the place of wildlife conservation.

**Snares and deadfalls**, G. A. PETRIDES. (Ohio State Univ.). (*Jour. Wildlife Mgmt., 10 (1946), No. 3, pp. 234-238, illus. 34*).—In some wildlife studies that involve trapping, snares and deadfalls may provide ways of taking specimens with less damage to the skins and with more food in the digestive tracts than by the slower killing steel traps. Furthermore, the materials for construction are found in the field or are easily carried. This paper describes the preparation and use of such devices, some of which are illustrated.

**Breeding birds of the beech-maple-hemlock community**, S. C. KENDEIGH. (Univ. Ill.). (*Ecology, 27 (1946), No. 3, pp. 226-245, illus. 3*).—Five biotic communities on the Helderberg Plateau adjacent to the Catskill Mountains of New

York are important in the analysis of bird distribution in ponds and marshes, grassy fields, mixed shrubs and small trees, hemlock-beech forest, and beech-maple-hemlock forest. The bird constituents of each are listed, and the sizes of the breeding populations in the last three were measured and are presented in tabular form. Differences in species composition and size of the bird population are noted for each type of forest. Comparison of the bird fauna of the mixed forests in this area with the deciduous forest biome to the south and the evergreen forest biome to the north indicates that it derives practically all of its members from these biomes. The biome and life-zone concepts—as far as they apply to this region—may be harmonized if the Canadian life zone and the evergreen forest biome are considered equivalent, the Carolinian faunal area of the upper austral life zone and the deciduous forest biome synonymous, and the Alleghanian faunal area of the transition life zone an ecotone or mixture and intermingling of the first two. There are 30 references.

**Helminth parasites of birds and mammals in western Massachusetts, J. S. RANKIN, JR.** (Univ. Conn.). (*Amer. Midland Nat.*, 35 (1946), No. 3, pp. 756-768).—Examinations of 9 species of birds (49 specimens) and 14 of mammals (122 specimens) revealed the presence of 40 species of helminths—17 nematodes, 13 cestodes, 8 trematodes, and 2 acanthocephalans; most of the distribution records appeared to be new. Many of the parasites found may prove important economically as seen by actual damage to surrounding tissues. There are 39 references.

**Collection and preservation of insects, P. W. OMAN and A. D. CUSHMAN.** (*U. S. Dept. Agr., Misc. Pub. 601* (1946), pp. 42+, illus. 42).—"Well-preserved and properly labeled specimens are essential to the identification of insects. This publication gives information on collecting, preserving, handling, mounting, and labeling insect specimens, on subsequent care of collections, and on recognition of the general insect groups or orders. It has been prepared in response to numerous requests from farmers, students, servicemen, and other individuals and groups interested in obtaining first-hand knowledge of insects by collecting them."

**The insect community found on a perennial peppergrass in southern New Mexico and southwestern Texas, V. E. ROMNEY.** (*U. S. D. A.*). (*Ecology*, 27 (1946), No. 3, pp. 258-262, illus. 3).—The insect community on a perennial peppergrass (*Lepidium alyssoides*) was studied from samples obtained by both cylinder and net methods at eight stations during December 1929-October 1931. The plant stands extended over an estimated 8,000 sq. miles. With the catch by the cylinder method as a basis, it was apparent that the sweep net adequately sampled some insects, but either over- or underestimated the abundance of others. The position of the insect on the plant or on the ground beneath it influenced greatly its catch by the net. Several economically important insects were found to breed on the plant in early spring and on maturing to become dispersed over agricultural crop and other host areas. Among these insects were the beet leafhopper, cowpea aphid, green peach aphid, false chinch bug, a flea beetle (*Phyllotreta albionica* (Lec.)), the diamondback moth, and a plant bug (*Lygus elisus* Van D.).

**New species of Florida Mayflies (Ephemeroptera), L. BERNER.** (Univ. Fla.). (*Fla. Ent.*, 28 (1946), No. 4, pp. 60-82, illus. 20).

**Additions to the Thysanoptera from the Island of Hawaii, F. A. BIANCHI.** (Hawaii. Sugar Planters' Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 12 (1946), No. 3, pp. 503-514, illus. 9).—This contribution adds 25 species of thrips to the 29 previously known; 3 are described as new.

*Conocephalothrips tricolor* [n. gen. and sp.], a new urothripid from Hawaii, F. A. BLANCHI. (Hawaii. Sugar Planters' Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 12 (1946), No. 3, pp. 499-502, illus. 1).

The identity and host plants of blossom midge in Hawaii (Diptera: Cecidomyiidae: *Contarinia*), D. D. JENSEN. (Hawaii Expt. Sta.). (*Hawaii. Ent. Soc. Proc.*, 12 (1946), No. 3, pp. 525-534).—It is concluded from the experiments reported that the gall midge *Contarinia maculipennis* Felt, which infests hibiscus in Hawaii, is the same species which breeds in tomato flowers and has been known in Hawaii under the names *C. solani* (Rübsaamen) and *C. lycopersici* Felt. Adults reared from hibiscus and *Jasminum sambac* were shown to breed on tomato, where their life cycle was indistinguishable from that of specimens reared on tomato. The biological evidence reported and a comparison of specimens from Hawaii with *C. lycopersici* from the British West Indies indicate that the former is probably the same species. In the West Indies, however, *C. lycopersici* has been recorded only from tomato, whereas the Hawaiian form is now known to breed in several unrelated plants. This renders it inadvisable at present to relegate the name *C. maculipennis* to synonymy. In Hawaii this midge has been reared from three species each of *Lycopersicum* and *Solanum*, as well as from *Capsicum frutescens*, *Brassica chinensis*, *Momordica charantia*, *Hibiscus*, and *J. sambac*. This wide host range in Hawaii—involving five plant families—is believed unique among the cecidomyiid gall midges. Only one other species has been recorded from plants of more than one plant family; in that case only two families were involved. There are 14 references.

Some aphid host records, G. F. KNOWLTON. (Utah State Agr. Col.) (*Pan-Pacific Ent.*, 22 (1946), No. 2, pp. 75-76).—An annotated list.

Biology and control of the ash lace bug *Leptocypha minor*, R. L. USINGER. (Univ. Calif.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 286-289, illus. 2).—*L. minor* McAtee differs from other tingid pests in that it is brown, compact in body form, and without lacy lobes. Adults hibernate in and around the trees. Eggs are laid on the lower sides of leaves in April, after which generations follow one another until October, the population building up to injurious numbers in late summer. The nymphs are flattened, living in colonies on the lower sides of leaves; they pass through five stages, leaving their cast skins adhering to the leaf long after they have gone. They cause a whitening of the leaves and black spotting of the lower surfaces due to fecal deposits. Both nymphs and adults were completely controlled by a 1-800 rotenone-oil mixture; 12 to 20 gal. of spray should be used, depending on the size of the tree. Good coverage—especially of the under surfaces of the leaves—is essential.

The long-horned beetles of Ohio (Coleoptera: Cerambycidae), J. N. KNULL. (Ohio State Univ.). (*Ohio Biol. Survey Bul.* 39 (1946), pp. 133-351+, illus. 139).—The object of this contribution is to aid students in identifying the cerambycid beetles occurring in Ohio. Species for which the author had no records but which were deemed likely to occur in the State are also included. Published keys are used or altered to fit Ohio forms, and some new keys are added. References are included for papers which will aid in identification or which contain phases of biology and economic importance.

A preliminary key to the species of *Pleocomma* (Coleoptera: Scarabaeidae), E. G. LINSLEY. (Univ. Calif.). (*Pan-Pacific Ent.*, 22 (1946), No. 2, pp. 61-65).

A new *Apanteles* from Hawaii (Hymenoptera: Braconidae), C. F. W. MUESEBECK. (U. S. D. A.). (*Hawaii. Ent. Soc. Proc.*, 12 (1946), No. 3, pp. 615-616).—*A. trifasciatus* n. sp., reared from cotton bolls, is described.

Sprayers for dispensing concentrated insecticides, H. O. SCHROEDER and A. W. LINDQUIST. (U. S. D. A.). (*Soap and Sanit. Chem.*, 22 (1946), No. 6, pp.

149-151, 173, *illus. 3*).—The liquefied-gas aerosol has given an entirely new concept of insecticide dispersion; development of the concentrated spray to a practical point brought up the problem of designing equipment that would render possible a wide application of the spray's advantages. Because properly atomized concentrated sprays are highly effective, many thousands of cubic feet of space can be disinfested with midget sprayers designed to contain small amounts of liquid. The sprayer developed and here described is a portable model which can be carried conveniently in a pocket. It consists essentially of a cylindrical liquid tank with a leather compression cup fitted to one end; a compression cylinder closed at one end and slightly larger than the liquid tank slides back and forth over it to provide air pressure with each forward stroke. Detailed descriptions of the parts are given.

**New insecticides, R. F. HOLLAND.** (Cornell Univ.). (*N. Y. State Assoc. Milk Sanit., Ann. Conf., 22 (1945), pp. 165-176*).—A brief presentation of present knowledge concerning DDT, benzene hexachloride (666 or Gammexane), RHothane D<sub>2</sub> or DDD, the aerosol bomb, and methyl bromide. Procedures are given for a successful fumigation "in any plant."

**Insecticidal properties of the indigobush (*Amorpha fruticosa*), C. H. BRETT.** (Okla. Expt. Sta.). (*Jour. Agr. Res. [U. S.], 73 (1946), No. 3, pp. 81-96, illus. 5*).—A new insecticidal plant has been found in *A. fruticosa*, studies of which were originally started because a color reaction indicative of the rotenoid group had been obtained from extracts of the seeds, stems, roots, and leaves. No rotenone was isolated, but a glycoside reacting to the rotenoid tests was discovered by the U. S. D. A. Bureau of Entomology and Plant Quarantine. The toxic principle has not yet been determined, but the term "amorpha" is used to designate it. Most of the amorpha occurs in resinous pustules on the pods; their size and abundance vary greatly. Seeds from individually identified plants have been analyzed biologically as a guide to selection or breeding of plants for high yields of amorpha. A few insects commonly inhabiting the indigobush have been identified and briefly studied. The bruchid *Acanthoscelides floridae* (Horn) was found to feed on seeds sufficiently to be considered a serious pest; it is parasitized by certain wasps. Laboratory and field tests with amorpha in dust and spray forms on 29 species of insects or mites show that it acts both as a stomach and a contact poison. Amorpha extracts thus far obtained have not included any highly toxic material; however, they have proved effective in controlling a few insects. One of the most interesting characteristics of the extract is its repellency, which persists for over 12 hr. Little is known on the toxicity of amorpha to mammals; apparently, however, it would be poisonous if taken internally. No effect on the skin has been observed.

**A toxicological comparison of *Derris* and *Lonchocarpus*, M. A. JONES, W. A. GEESDORFF, and E. R. MCGOVAN.** (P. R. Fed. Expt. Sta. and U. S. D. A.). (*Jour. Econ. Ent., 39 (1946), No. 3, pp. 281-283*).—On the assumption that the samples tested were more or less representative of the species and varieties considered in this study and that the toxicity to houseflies is a fair measure of the toxicological value of a sample, it seems that—other factors such as root yield being equal—the Sarawak Creeping or the high-rotenone Changi No. 3 varieties of *Derris* would be the best choice for producing insecticidal material. From comparisons of chemical criteria with toxicological values it appeared that the colorimetric determination of rotenone plus rotenoids gave the best chemical estimate of the toxicity of the samples, though it varied considerably from the biological assay.

**Effect of mineral composition and particle size in dispersants on toxicity of rotenone dusts, H. F. WILSON and M. L. JACKSON.** (Wis. Expt. Sta.).

(*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 290-295).—The presence of small particles—particularly of colloidal range—had a hindering effect on the toxic values of rotenone dusts. When the average particle size of a dispersant was too large (60-mesh) the toxic efficiency of the dusts was less than with intermediate sizes (200- to 325-mesh); if the majority of the particles were very small ( $1\mu$  to  $10\mu$ ), the efficiency was greatly reduced. The colloidal particles found in many dispersants tended to cover the cube and derris particles so that they failed to come into contact with an insect. The main sources of colloidal particles in dispersants are free ferrous and ferric oxides and chloritoid minerals (especially those high in ferrous iron) which are easily fractured to small particle size. Pure quartz proved to be the best available dispersant for rotenone but is undesirable because of its high abrasive qualities. Pyrax (pyrophyllite, quartz, and mica) was found to be an excellent dispersant; being comparatively free of ferrous and ferric iron, it contains few colloidal particles. This material is high in quartz—giving it the properties of quartz—but with less of the abrasiveness at the cleavage planes than pure quartz on account of the lubricating qualities of the pyrophyllite cleavage planes. Talc is also a good dispersant when few colloidal particles are present, but if ferrous or ferric iron occurs in marked degree, colloidal particles are usually there in sufficient amount to influence the efficiency of rotenone dusts. Iron—either ferrous or ferric—does not cause direct deleterious chemical effects on rotenone.

**Insect control with DDT**, L. HASEMAN, G. D. JONES, and C. W. WINGO (*Missouri Sta. Cir.* 309 (1946), pp. 7, illus. 2).—This circular presents information on the available forms of DDT and directions for its use in the control of insect pests of livestock, poultry, household, garden, and fruits.

**The use of DDT residual sprays in the home**, L. S. HENDERSON and H. H. STAGE. (U. S. D. A.). (*Pests*, 14 (1946), No. 6, pp. 16, 18).—A brief summary of the present status of DDT for use in homes, including solutions, emulsions, and suspensions and the precautions in using it as a residual spray.

**D. D. T.—its intelligent use this season**, R. H. DAGGY. (Minn. Expt. Sta.). (*Minn. Hort.*, 74 (1946), No. 5, pp. 67-69, illus. 1).

**Sabadilla and DDT to control the hairy chinch bug**, R. S. FILMER and C. L. SMITH. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 309-313).—In 1945 tests, 10 percent sabadilla dust and 10 percent DDT dusts applied at the rate of 100 lb. per acre gave over 90 percent reduction in chinch bug populations. DDT also proved satisfactory when applied as a spray and when incorporated with top-dressing applications.

**Beet leafhopper selection of bean varieties and its relation to curly top**, H. C. HALLOCK. (U. S. D. A., Idaho Expt. Sta., et al.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 319-325, illus. 1).—In selectivity trials of 20 varieties of garden beans commonly grown in south-central Idaho—using special revolving cages—a significantly higher percentage of leafhoppers chose the garden varieties in preference to the curly top-resistant field variety Red Mexican; Red Valentine, Bountiful, Kentucky Wonder, and Plentiful were the varieties proving most attractive. In greenhouse tests, Plentiful, Bountiful, Longfellow, Asgrow Black, Valentine, Pencil Pod Black Wax, and Sure Crop Black Wax developed significantly more curly top than the remaining 13 varieties when a large number of viruliferous leafhoppers were allowed a choice. All 19 varieties of garden bean exhibited significantly more curly top than either Red Mexican or Great Northern commercial dry beans. The greenhouse findings in general held true under south-central Idaho field conditions. It is concluded that in years of medium leafhopper populations such varieties as Burpee Stringless Greenpod, Idaho Refugee, and Landreth Stringless Greenpod can be grown with

less danger of loss from curly top than the other varieties tried; losses in bean yields can thus be decreased in this area by avoiding use of highly susceptible varieties in years when high leafhopper populations are expected.

**Observations on corn borer and corn earworm in 1943**, T. H. PARKS. (Ohio State Univ.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 29 (1944), pp. 62-71).

**The cotton aphid**, D. ISELY (*Arkansas Sta. Bul.* 462 (1946), pp. 29, illus. 3).—The cotton aphid causes serious losses to cotton only after dusting the plants with calcium arsenate for boll weevil control; its control is thus a part of the boll weevil problem. Because of their remarkable reproductive capacity, outbreaks of aphids may build up with great rapidity; under optimum conditions cotton aphids may begin producing young within 4 days after birth. Ordinarily they are held in check by insect enemies, but dusting with calcium arsenate reduces the numbers of such enemies. Other factors also influence the abundance of cotton aphids, though none are as important as dusting. The most favorable temperature for their reproduction is 20° C.; this is not only lower than that of any other important insect pests of cotton but is lower than that of the insect enemies of aphids. For this reason cotton aphids often appear in conspicuous numbers early and late but are never important in midsummer unless cotton is dusted. Cotton plants growing on soils well supplied with nitrogen are more favorable to aphid development; the recent soil improvement practices, through a wider use of legumes, may be expected to make the tendency for aphid outbreaks somewhat greater. The possibility of the development of an aphid outbreak after dusting increases with the number of dust applications. Outbreaks also develop more rapidly when dusting in a region is general. Where spot dusting only is practiced for boll weevil control, the likelihood of aphid injury is relatively small.

A cotton aphid outbreak can be controlled by dusting with calcium arsenate containing 3 percent nicotine. This mixture may be used to control both the cotton aphid and the boll weevil; for the cotton aphid alone, nicotine may be combined with hydrated lime. In some States the inclusion of 2 percent nicotine in alternate applications of calcium arsenate or of 1 percent nicotine in every application is recommended as a precautionary measure against cotton aphid outbreaks. In a limited test, 0.5 percent rotenone combined with calcium arsenate appeared to be effective against the cotton aphid provided it was applied to the underside of the foliage and came in actual contact with the aphids. In 3 years' experiments, dusting sulfur was effective in killing the aphids actually coming into contact with it, but further trials are needed before final recommendations can be made. There are 37 references.

**Damage by *Euschistus impictiventris* and *Chlorochroa sayi* to sugar beets grown for seed**, O. A. HILLS and K. B. MCKINNEY. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 335-337, illus. 2).—In field-cage trials (1944) to determine the effect of *E. impictiventris* Stål. on the beet seed crop and to compare the damage from this insect with that by the Say stinkbug, both were found to cause a reduction in the viable seed balls produced, as well as in the number of sprouts per viable seed ball. Indications were, however, that the latter has a tendency to cause slightly more damage.

**What about the oriental fruit moth in 1946?** E. H. WHEELER. (N. Y. State Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 14-15, illus. 3).—The author briefly reviews some of the activities of this insect pest and its enemies as a basis for forecasting the probable damage of the season; early injury in 1946 seemed to be about normal. As to control, until the coming of DDT no insecticidal program has proved practical for New York

State. DDT as a wettable powder can be applied to peach trees at the rate of 1 lb. actual DDT to 100 gal. water; with properly timed applications and thorough coverage, it is claimed that this material will give satisfactory control of the oriental fruit moth. Parasites of this insect, however, are also readily killed, so that improper timing of applications could result in destruction of the parasites and thus in poor moth control, therefore recommendations for the general use of DDT against the oriental fruit moth await further experimentation.

**Control of the sex ratio in *Macrocentrus ancylivorus*,** C. H. MARTIN and G. L. FINNEY. (Univ. Calif.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 296-299).—The authors describe a technic for handling this parasite of the oriental fruit moth in the mating room, through which the proportion of females was increased 19 percent by decreasing the light intensity in the mating room—so as to reduce activity and promiscuous mating—and by allowing a 24-hr. emergency period. Population densities within the levels described did not influence sex ratios at the lower light intensities. Superparasitism by supposedly impregnated females increased the proportion of females.

**Life history of the European red mite,** L. R. CAGLE (*Virginia Sta. Tech. Bul.* 98 (1946), pp. 19, illus. 7).—In life history studies of the European red mite in the insectary at Blacksburg, Va. (1943-44), a technic was developed for confining the mites on a small section of an apple leaf for rearing; a closed celluloid cell was developed for use in obtaining data on the adult phases, and a method is described for getting the winter eggs. The mite overwinters in the egg stage; hatching began when apple buds were beginning to show pink and continued until the petals were falling. The first winter eggs were deposited by females emerging on August 28 in 1944; 9 generations were reared, and some tenth-generation eggs hatched but failed to develop to maturity. Summer eggs were deposited from about May 10 until September 30 in 1943 and from May 4 until September 27 in 1944; the last eggs hatched on October 19 in 1943 and on October 8 in 1944. The incubation period ranged from 5 days at an average temperature of 76.1° F. in 1943 and 75.2° in 1944 to 20 days at 55.8° in 1943. The larval period, both sexes included, was 1 to 7 days, the protonymphal period 1 to 8 days, and the deutonymphal period 1 to 9 days. The minimum time required for development from hatching to adult was 4 days for each sex; the maximum was 19 days for males and 22 for females. The preoviposition period was 1 to 17 days; the average was 2.3 days in 1943 and 2.4 in 1944. The maximum oviposition period was 25 days; the average for 45 females was 12.4 in 1944. The maximum number of eggs deposited by a female was 69; the average for 45 females was 18.8. The length of life of females was 5 to 39 days and average 18.8 days. All mites reared from unfertilized eggs were male. Mites reared from eggs deposited by females that had been exposed to males were 62.8 percent females and 37.2 percent males.

**The control of spittle insects in strawberry plantings,** F. G. MUNDINGER. (N. Y. State Expt. Sta.) (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 299-305, illus. 5).—The economic forms of these insects are said to be represented by only a few species, but one of these, *Philaenus leucophthalmus* L., is often destructive to strawberries though it breeds abundantly on innumerable host plants. In the tests reported upon, 1 percent rotenone dust with or without an oil conditioner and used at the rate of about 50 lb. per acre, or a spray consisting of 5 lb. of derris in 100 gal. of water with a spreader and applied at the rate of 300 gal. per acre, proved equally effective against spittle insects attacking strawberries, each giving high reductions in the populations. A 5 percent DDT dust with an oil conditioner was also very effective, and certain mixtures below this concentration gave definite promise as controls. Under optimum weather conditions and properly timed,

a 0.5 percent rotenone dust with an oil conditioner applied at about 50 lb. per acre gave satisfactory control. Plain hydrated lime applied at 500 lb. per acre under favorable conditions also gave a considerable amount of protection. Most of the dusts containing nicotine sulfate were ineffective; neither were those containing Lethane, DN, pyrethrum, or plain talc promising as used. Rotenone therefore seems specific for this pest and has the added advantage of leaving a light, almost invisible, deposit. The optimum time for treatment is after most of the eggs have hatched but before many of the nymphs have reached the fourth and fifth instars; in these New York State tests it fell between the middle and last of May. In all cases the material should be so applied as to reach all spittle masses.

**Dusting blueberries to control the cranberry fruitworm, B. B. FULTON.** (N. C. Expt. Sta.) (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 306-308.)—The experimental results reported indicate it possible to control the cranberry fruitworm by dusting with cryolite or DDT; further investigation is needed, however, to indicate whether other materials may be substituted or whether dusts will be effective under more normal and more adverse weather conditions.

**[Report on studies of insects and weather as affecting cranberries], H. J. FRANKLIN.** (Mass. Expt. Sta.) (*Cranberries*, 11 (1946), No. 2, pp. 22, 24.)—A brief report (1944-45) on cranberry insects and their control, new insecticides, and winterkilling and frost injury.

**Cuban laurel thrips control on *Ficus benjamini*, D. O. WOLFENBARGER.** (Fla. Expt. Sta.) (*Fla. Ent.*, 28 (1946), No. 4, pp. 82-83.)—A severe infestation of the Cuban laurel thrips is reported on a tree at Homestead, Fla. In a comparison of sprays applied by knapsack sprayer, hexachlorocyclohexane gave almost perfect control, followed in order by DDT plus Lethane 60, DDT alone, and nicotine sulfate. No foliage injury was apparent from any of the treatments.

**The control of storage insects in corn seed, H. K. PLANK.** (P. R. Fed. Expt. Sta.) (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 314-319, illus. 1.)—In warm climates corn seed becomes heavily infested by the rice weevil soon after harvest; if then kept under natural conditions it quickly loses its viability because of further attacks by this and other storage pests. In experiments with USDA-34 sweet corn, dipping the newly harvested ears in a freshly prepared water suspension of copper carbonate—with or without wetting agent—failed to prevent either early or late infestation. Mixing the carbonate as a dust with shelled seed (1-448 by weight) a month after harvest—as recommended for smut control—was equally ineffective, though it tended to hasten sprouting; phenothiazine at the same rate was not only ineffective but injured the seed. Phenoxathiin-bentonite kept the infestation lower and for a longer time than any other treatment used except CS, fumigation and isolation, but with no significant improvement in germination. Over a 6-mo. period none of these dust treatments of shelled seed gave more satisfactory results than similarly applied hydrated lime 1-40 by weight. Rolling the partly dried seed ears in hydrated lime alone or in lime containing copper carbonate, phenothiazine, or phenoxathiin-bentonite at a time when the grains had separated enough for the dust to penetrate to the cob retarded infestation and prevented serious damage for a month after harvest. The dosages were all adjusted so that the proportion of chemical used would be equivalent to 1-448 by weight of seed after shelling and that of lime to 1-40. During the next 5 mo. of common storage, however, none of these combinations gave significantly better control than hydrated lime alone. From the practical standpoint—all things considered—rolling the partly dried ears in hydrated lime gave the most satisfactory results.

**Susceptibility of edible soya products in storage to attack by *Tribolium confusum* Duv., C. E. MICKEL and J. STANDISH** (*Minnesota Sta. Tech. Bul.* 175

(1946), pp. 28+, *illus.* 9).—These studies indicated that the confused flour beetle is a much less serious pest of soybean flours and grits than of cereal products. All soybean flours and grits may become slightly infested and some damage may occur when the relative humidity in storage is above 50 percent. Full-fat soybean flour is likely to be more heavily infested than other soybean flours or grits. Low-fat-extracted soybean flour and fine grits were most attractive to the females for oviposition; both of these materials were less favorable for development of the insect than full-fat soybean flour. Any soybean flour or grit combined with cereals—either in unfinished form such as pancake flours or in finished form such as baked goods—was more likely to be infested and damaged by this pest than the soybean flours and grits in their original processed form. The rate of larval development was greatly decreased in soybean flours and grits, resulting in a prolonged larval period. Conspicuous increases in the number of larval instars accompanies decreases in the developmental rate.

**DDT to control hide beetles**, D. D. JENSEN and F. G. HOLDAWAY. (Hawaii Expt. Sta.) (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 283–286).—In tests to determine the comparative efficiency of various materials against damage to rabbit hides by larvae and adults of the hide beetles (*Dermestes vulpinus* F. and *D. cadaverinus* F.), DDT proved outstandingly superior. In spray or dust form it provided excellent protection for at least 371 days after a single treatment and proved equally effective on fresh or dried hides. No evidence of feeding was discernible on hides treated with 10 percent DDT dust or with 2, 3, 4, or 5 percent spray and exposed to continual reinfestation by adults and larvae for 357 days; a slight but negligible feeding occurred, however, following treatment with 2, 3, 4, or 5 percent dust. The maximum damage to hides treated with 1 percent dust or spray did not exceed 5 percent of the hide surface. Sprays proved more toxic to adults than dusts at the same concentration. Oviposition was not prevented by the treatments, but was inhibited in direct proportion to the DDT concentration used; sprays were more effective than dusts in preventing oviposition. DDT did not prevent eggs from hatching, but the larvae emerging died before they were able to feed perceptibly. All concentrations of dusts and sprays tried provided complete kills of the first instar larvae.

**What to do about polilla**, G. N. WOLCOTT (*Puerto Rico Univ. Sta. Bul.* 68 (1946), pp. 29+, *illus.* 4).—Damage by the “polilla de madera”—the West Indian dry-wood termite *Cryptotermes brevis* (Walker)—to wooden houses and trim, floors and ceilings of concrete houses, and to furniture, books, and clothing in Puerto Rico rank it with the most injurious insects of the island. New colonies are formed by a pair of adults, after they have broken off their transparent iridescent wings, seeking shelter in books or piles of papers, in drawers and on the underside and in the hidden parts of furniture, and under the caning or wicker or in the bottom of the rockers of chairs. Infestations can be prevented by purchasing furniture made entirely of woods which the polilla does not like to eat, such as West Indian mahogany or some of the other native hardwoods of Puerto Rico, or many of those of tropical America. No furniture is more resistant to attack than the most susceptible piece of wood used in its construction—and practically all the furniture woods of the Temperate Zone are very susceptible.

The most susceptible wood can be made immune to attack if every exposed surface is treated with a dilute solution of  $\text{CuSO}_4$  or  $\text{ZnCl}_2$  in water, or of 5 percent pentachlorophenol in organic solvents. An ounce of  $\text{CuSO}_4$  or  $\text{ZnCl}_2$  to 1 gal. of water is double the strength needed, but increasing the amount does not protect untreated surfaces or make up for carelessness in application. To kill termites in infested furniture, the wood surrounding them may be poisoned by injecting into their tunnels a 0.3 percent solution of arsenic as 1.25 gm. of sodium arsenite in

100 cc. of water; or pentachlorophenol may be used to kill by suffocation. In infested wooden houses, use of sugarcane bagasse wallboard impregnated with arsenic by the manufacturer is recommended when repairs are to be made; the bagasse is more attractive to the termites than the wood, and they eat it by preference and die.

A small, dark-colored new *Kaloterme*s from Guatemala, T. E. SNYDER (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 48 (1946), No. 6, pp. 158-160).—Specimens of the nonsubterranean termite *K. nigratus* n. sp.—here described—were intercepted at San Francisco in a log from Guatemala.

An international termite exposure test—fifteenth progress report, G. M. HUNT and T. E. SNYDER. (U. S. D. A.). (*Pests*, 14 (1946), No. 6, pp. 20-30).—This is the fifteenth (E. S. R., 88, p. 787) of a series of annual progress reports comparing the effectiveness of various preservatives in protecting wood from decay and termites in various parts of the world; the data are presented in tabular form. "These tests must continue for many years and be supplemented by actual use experience on a commercial scale before the respective preservatives can be evaluated fully. In the meantime, the use of the partial results for commercial promotion can be very misleading."

House ants, E. A. BACK (U. S. Dept. Agr. Leaflet 147, rev. (1946), pp. 8, illus. 5).—A revision (E. S. R., 78, p. 660).

Cattle lice, their biology and control, J. G. MATTHYSSE ([New York] Cornell Sta. Bul. 832 (1946), pp. 67, illus. 45).—Every winter cattle lice are serious pests in many dairy and beef herds in the northern United States; nevertheless, there has been almost no detailed work on these insects under these conditions. The present study was undertaken to find the best methods for controlling these pests under northern dairy conditions, including work on the biologies of all five species of cattle lice recorded as parasitizing domestic cattle to gain information of possible use in relation to control and investigations of the relative efficiencies, concentrations, and methods of application of various insecticides for louse eradication. The investigation involved the distribution of cattle lice in New York State, seasonal variations in their populations, variations in the resistance of host breeds, the economic effects of infestations, the life histories and biologies of cattle lice (*Linognathus vituli* (L), *Solenopotes capillatus* Enderlein, *Haematopinus tuberculatus* (Bermeister), the short-nosed cattle louse, and the cattle biting louse), methods by which the lice are transmitted, and their control. The illustrations include four colored plates.

The general conclusions from the two-season control experiments here reported for New York conditions and from work by others (over five pages of references) are as follows: Dusts proved best for use in New York State, those containing 10 percent or more of derris or cube (0.5 percent or more actual rotenone) controlling all species. Finely ground sabadilla can be used as an effective substitute for rotenone. Nicotine was ineffective. Lethane 60, Lethane B71, Thanite, Velsicol, Phenothioxin, Dow K 1875, and pyrethrum have considerable toxicity to cattle lice but apparently cannot be relied upon for complete control; Thanite and Lethane B71 appeared more toxic than Lethane 60 to cattle lice. A combination of Lethane B71 and nicotine, as well as some samples of yam bean, seemed to have promise for controlling all species of cattle lice, but more work is necessary before definite conclusions can be drawn for these insecticides. Hellebore was low in toxicity to cattle lice.

The cattle biting louse can be controlled by heavy application of almost any finely divided dry material; wettable sulfur, diatomaceous earth, and sodium fluoride were all effective. There is disagreement in the literature on the effectiveness of sodium fluoride against sucking lice. Since eight workers have stated that it is ineffective, it must be concluded that this material cannot be relied

upon to control all species of cattle lice. DDT was fairly high in toxicity but did not appear as effective as rotenone or sabadilla in dusts; again further work is necessary before definite conclusions can be drawn. Cattle fly sprays cannot be relied upon against lice. Neither does the aerosol principle seem promising as a method of application. Spot dusting to evaluate louse powders was inaccurate, mainly because lice migrate too rapidly into dusted areas; also, this method gives no indication of the residual action of the insecticides involved.

The species of cattle lice vary greatly in susceptibility to different insecticides; nevertheless it can be said in general that *S. capillatus* is the most resistant species, although very susceptible to nicotine. The short-nosed cattle louse is the next most difficult to control. *L. vituli* is apparently the easiest of the sucking lice to control. The cattle biting louse is in general the most susceptible to insecticides—and even to inert diluents; a laboratory method for evaluating the toxicity of insecticides to it has been worked out which proved useful for evaluating quickly and accurately the toxicity of a series of materials—or various samples of the same material—to this one species.

**Observations on tick repellents**, C. N. SMITH and H. K. GOUCK. (U. S. D. A.) (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 374–378).—In tests at Savannah, Ga., under controlled conditions a moderately high degree of protection from the lone star tick was obtained with Indalone and dimethyl phthalate. Benzyl benzoate, bisethylxanthogen, and pyrethrum were also of some value as repellents. In a field test at Camp Bullis, Tex., with troops exposed to light infestations of ticks, Indalone, dimethyl phthalate, and a rotenone-sulfur dust reduced the tick attachments. When used in the field by troops exposed to heavy tick infestations, both dimethyl phthalate and 6-2-2 (dimethyl phthalate 6, Indalone 2, and Rutgers 612, 2 parts by volume) gave substantial reductions in tick attachments when applied to the margins of the clothing. Reductions were greater when the clothing was treated after 3 than after 5 days. Reductions were slightly greater when the entire garments were sprayed than when the margins only were treated from a bottle.

**DDT to control insect pests affecting livestock**, W. G. BRUCE and E. B. BLAKESLEE. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 367–374, illus. 1).—This work in the southeastern United States during 1944–45 began with preliminary tests on about 3,000 head of livestock in 14 dairy barns. A serious outbreak of stableflies in central Florida was brought under control by passing the animals through a wading vat containing a 2 percent DDT emulsion and spraying their backs with the same material. In tests in South Carolina and Florida two applications of 2.5 percent DDT emulsion sprayed on cattle kept horn flies well below nuisance numbers for the rest of the season. Dipping the animals in a 0.2 percent emulsion was less effective than spraying them with a 2 percent emulsion. One application of a spray containing 2.5 percent DDT—emulsion or water suspension—to the interior of dairy buildings controlled houseflies for the season where the interior was painted and ceiled and where good fly sanitation was practiced.

In large-scale tests (1945) about 26,000 head of livestock and 120 dairy barns were treated with water suspensions of various strengths prepared from water-dispersible DDT powder. Dipping the cattle in a 0.23 percent suspension completely controlled horn flies for 10 to 14 days, but there was no apparent effect on other pests except possibly cattle lice. Complete horn fly control was obtained for 2 to 3 weeks by spraying with a 0.5 percent suspension; this was also somewhat effective against fresh-water mosquitoes and for a month against houseflies in barns. A 1 percent suspension as a spray controlled all insects to about the same extent as half that concentration. A 2.3 percent suspension completely controlled horn flies for 4 to 7 weeks, was very effective against houseflies for

over 3 mo. when sprayed on barns, and was effective for more than 3 weeks against houseflies in hogpens; this suspension was also very effective against stableflies when applied to livestock and to resting places of the flies. It completely controlled fresh-water mosquitoes when applied as a spray to livestock and buildings and was effective against cockroaches in barns; it also appeared satisfactory for controlling cattle lice if the animals were thoroughly sprayed; furthermore, the screwworm fly population was reduced, and the Gulf Coast tick was controlled by it. No apparent injury to any of the animals was observed. It is estimated that the DDT sprays were responsible for a minimum gain of 700,000 lb. of beef and 30,000 gal. of milk during the month following these applications.

**Use of new insecticides in dairy plants**, E. H. FISHER. (Univ. Wis.). (*Natl. Butter and Cheese Jour.*, 37 (1946), No. 7, pp. 50-58).—An address.

**DDT spells death to flies in dairy barns**, H. H. SCHWARDT. ([N. Y.] Cornell Expt. Sta.) (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 1-2, illus. 1).—Large-scale tests are said to show that DDT sprays are effective, safe, and practical for killing flies in dairy barns. Only two applications yearly were found necessary to control flies under New York State conditions.

**DDT to control insects affecting man**, E. F. KNIPLING. (U. S. D. A.). (*Jour. Econ. Ent.*, 39 (1946), No. 3, pp. 360-366).—Within the past 3 yr. DDT has become one of the most effective agents known against certain insects affecting man, including mosquitoes, lice, flies, fleas, and bedbugs; its importance for controlling diseases transmitted by these insects has also been demonstrated. The data drawn upon for this paper were obtained largely in connection with studies conducted at Orlando, Fla., where investigations on the control of insects and arachnids of importance to the armed forces have been under way since 1942. An attempt is here made to summarize present knowledge on the use of DDT against the more important insects affecting man, with particular emphasis on how the insecticide can be employed in practical operations and the type of formulations that have been found useful. There are 27 references.

**Aerosol toxicity: Effect of the nonvolatile content of a DDT aerosol on mortality of houseflies**, J. H. FALES, E. R. MCGOVAN, and L. D. GOODHUE. (U. S. D. A.). (*Soap and Sanit. Chem.*, 22 (1946), No. 6, pp. 157-158, illus. 2).—Tests in a Peet-Grady chamber indicated that a DDT-dibutyl phthalate (1-14)-Freon aerosol will give the highest kill of houseflies when the nonvolatile content is about 15 percent. The particle-size distribution curves are given for 10, 15, 20, and 30 percent of nonvolatile material; the most toxic aerosol had 50 percent of its volume in drops below  $3\mu$  in radius and the remainder in drops of  $3\mu$  to  $20\mu$ ; aerosols finer or coarser than these limits proved less toxic.

**A re-emphasis on strong colonies and forces of honeybees**, D. O. WOLFENBARGER. (Del. Expt. Sta.). (*Gleanings Bee Cult.*, 74 (1946), No. 6, pp. 327-329, illus. 5).—A review, with five literature references.

**Some State apiarists are opposed to sulfa drug treatment**, L. HASEMAN. (Univ. Mo.). (*Amer. Bee Jour.*, 86 (1946), No. 7, pp. 276-277).—The author reviews briefly some of the more urgent objections to the sulfa-drug treatment of American foulbrood raised by State apiarists at the St. Louis conference, March 26, 1946, and refers to the 30 years' work at the Missouri Station culminating in the publication previously noted (*E. S. R.*, 92, p. 819).

## ANIMAL PRODUCTION

**Effect of temperature and length of storage on ensilage made from cooked white potatoes**, I. LINDAHL, R. E. DAVIS, and N. R. ELLIS. (U. S. D. A.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 279-284).—This study was undertaken to

determine the best method of adaptation to American conditions of the considerable amount of European work on the ensiling of cooked potatoes, and particularly the effect of temperature and the chemical changes during the fermentation process and the storage period. Experimental silos of various types were employed, with storage at low (35° F.), medium (63°), and high (85°) temperatures from 2 weeks to 1 yr.

As indicated, especially by the pH and starch values, temperature had a decided influence on the rate of fermentation and the final composition of the silage. At 85° most of the fermentation took place during the first 2 weeks, while changes at 63° occurred up to 6 mo., and at 35° there was putrefaction but no noticeable fermentation within a year. The loss of nutrients was significantly greater at high than at medium temperatures, and 60° during the fermentation is suggested. The losses at the end of 6 weeks for the silage stored in trenches were 20.93 percent for dry matter and 48.37 percent for carbohydrates. In a feeding test of 15 days this silage was consumed very readily by six pigs averaging 53 lb. in weight with a gain of 1.6 lb. per day and a food consumption per pound of gain of 4.24 lb. silage, 0.74 lb. corn, 0.3 lb. protein mixture, and 0.014 lb. minerals.

**Fused tricalcium phosphate fertilizer: Possible animal feed supplement,** D. E. WILLIAMS, F. L. MACLEOD, E. MORRELL, and F. P. JONES. (Tenn. Expt. Sta.) (*Indus. and Engin. Chem.*, 38 (1946), No. 6, pp. 651-654).—The experiments described in this paper were designed to test the suitability of fused tricalcium phosphate fertilizer as a mineral feed supplement for animals. This is a product containing 0.4 percent fluorine, and is prepared by a thermal process by which the fluorapatite of the raw rock is decomposed and 85 percent or more of the component fluorine is expelled. The tests consider the physiological availability of the phosphorus and the toxicity of the unremoved fluorine.

The feeding tests described in preliminary reports (E. S. R., 93, p. 224) indicated that when fused tricalcium phosphate of no more than 0.8 percent fluorine content was fed to the animals over a 90-day period as 1 percent of their diet, to provide a total phosphorus level of 0.2 percent, they showed normal growth and phosphorus retention. Reproduction trials now show that the fused phosphate, fed in a diet with total phosphorus level of 0.4 percent, was 75 to 93 percent as effective as a standard material of established phosphorus-feeding value.

**Zinc toxicity in rats: Antagonistic effects of copper and liver,** S. E. SMITH and E. J. LARSON. (U. S. D. A.). (*Jour. Biol. Chem.*, 163 (1946), No. 1, pp. 29-38, *illus.* 1).—The feeding of zinc (0.7 percent of the diet as carbonate) to young rats induced a microcytic and hypochromic anemia and subnormal growth. The additional feeding of copper (0.2 mg. daily, as the sulfate) maintained the hemoglobin at significantly higher levels and a mixture of iron (0.2 mg. daily, as ferric pyrophosphate), copper, and cobalt (0.2 mg. daily, as cobaltous chloride) essentially maintained hemoglobin at normal levels, although iron or cobalt supplements alone had no effect. Iron, copper, and cobalt had no effect on the subnormal growth of zinc-fed rats, but supplements of a liver extract produced a highly significant growth response. The liver activity was apparently not due to pantothenic acid.

"Studies such as this point to the possible occurrence of relative deficiencies in addition to absolute deficiencies in the field; that is, animals may be deficient in one mineral relative to an excess of some other."

**Methods for identifying feeds and measuring their rate of passage through the rumen of cattle,** W. BURROUGHS, P. GERLAUGH, E. A. SILVER, and A. F. SCHALK. (Ohio Expt. Sta.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 272-278, *illus.* 1).—Two methods are presented for identifying individual feeds within the rumen of two steers with rumen fistulae while feeding a mixed ration containing

corn, hay, and protein supplement. A chemical method of identification was based upon mathematical treatment of the principal nutrients contained in the feeds fed and the nutrients present in the rumen ingesta. This method was checked, in part, by physically separating out the corn contained in representative samples of rumen contents. The general agreement in results obtained by the two methods was suggestive of their over-all accuracy.

**Rations for fattening beef cattle in Montana.** R. T. CLARK, E. R. MCCALL, and R. R. WOODWARD (*Montana Sta. Cir.* 184 (1946), pp. 8).—Feeding trials with grade Hereford steers for periods of 183 to 252 days as required to bring the steers to an average weight of 800 lb. or more at the time of marketing are reported. The rations tested consisted largely of home-grown feeds and dried molasses beet pulp.

A ration of one-half each of dried molasses beet pulp and ground barley fed with alfalfa produced greater gains, more finish, and a higher net return per steer than a ration containing three-fourths barley and one-fourth dried molasses beet pulp plus alfalfa hay. A ration of 45 percent each of ground barley and dried molasses beet pulp, 10 percent linseed cake, and alfalfa produced greater gains but slightly lower net returns per steer than a similar ration without linseed cake.

Wheat and dried molasses beet pulp fed in equal amounts, plus alfalfa hay, proved to be quite comparable to barley, dried molasses beet pulp, and linseed cake, plus alfalfa hay, in net return and feed costs per hundredweight gain. However, the latter ration resulted in slightly heavier average daily gains. A ration containing 50 percent wheat, 30 percent barley, 20 percent oats, and alfalfa hay produced lower gains at a higher cost than did a ration of wheat, dried molasses beet pulp, and alfalfa hay.

Dried molasses beet pulp when fed in combination with barley and alfalfa hay seemed to reduce the incidence of bloat but did not entirely eliminate it. Steer calves, weaned the latter part of October and put on concentrate feed, suffered most trouble from bloat during the month of December or before they received a large amount of concentrates.

On the basis of the results presented, two rations with alfalfa hay are recommended for fattening steer calves. One of these consists of ground barley, dried molasses beet pulp, and linseed cake 45 : 45 : 10. The other consists of ground wheat and dried molasses beet pulp 50 : 50.

**The relation of certain objective measurements to weights of beef cattle.** J. J. WANDERSTOCK and G. W. SALISBURY. (Cornell Univ.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 264-271, illus. 1).—With a view to developing a practical means of estimating the weight of beef cattle where there is no access to scales, a study was made of the relationship between the heart girth measurement and the body weight of 100 Aberdeen-Angus and 45 Hereford Good-to-Choice fat yearling steers ranging in weight from 640 to 1,150 lb. Also, data were obtained on height at withers, patella or round, and body length for 36 of the Aberdeen-Angus and 30 of the Hereford steers. Heart girth measurements and body weights were also obtained on 27 Aberdeen-Angus heifers and cows of the university herd, ranging in age from 2 to 12 yr.

The coefficients of correlation between heart girth and body weight were 0.91 for the Hereford steers, 0.89 for the Aberdeen-Angus steers, 0.88 for all steers, and 0.93 for the heifers and cows, all highly significant statistically. These coefficients were of a higher magnitude for the lighter steers as compared with the heavier steers, indicating a greater accuracy in predicting the weight of the former. The correlation coefficient for the cows was smaller than that for the heifers, each being smaller than the correlation coefficients for the steers. A

calculation of the regression of the logarithms of actual live weight on the logarithms of heart girth measurements, indicating a straight line relationship, showed that the Aberdeen-Angus steers were lighter than the Hereford steers in relation to their heart girth measurements. The regression line for the heifers and cows indicated that they were heavier than the steers in relation to their heart girth measurements, especially at the larger tape measurements. Regression equations, in logarithms, for predicting weight from heart girth measurements are presented. Calculations of the interrelationships between heart girth, height at withers, patella or round, body length, the Minnesota formula (heart girth  $\times$  heart girth  $\times$  body length  $\div$  300), and body weight for all of the steers showed that the correlation coefficients were highly significant for every combination except for that between height at withers and patella, which was significant. There was a trend towards greater significance in these relationships for the lighter steers as compared with the heavier steers. The most significant single measure for estimating weight was the heart girth measurement, which was only slightly less significant than the more detailed estimation obtained by using the Minnesota formula.

**Variation in determinations of digestive capacity of sheep,** E. B. FORBES, R. F. ELLIOTT, R. W. SWIFT, W. H. JAMES, and V. F. SMITH. (Pa. Expt. Sta.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 298-305).—In this study 22 yearling Merino wethers were used as subjects in a digestion experiment with clover-timothy hay as the only feed. The standard deviations of the values determined for digestibility of the nutrients of the hay were reasonably low except with reference to lignin as determined by difference. A table is presented giving the standard errors and the minimum difference required between determinations with 1 to 10 sheep for odds of significance of 19 to 1. While the number of sheep required per experimental treatment depends on the permissible variability of results, it is concluded that 5 sheep per treatment are a sufficient number for usual purposes if the experimental technic is efficient, and if the sheep have been successfully treated on account of parasites of the alimentary tract.

**Palatability for sheep and yield of hay and pasture grasses at Union, Oregon,** D. E. RICHARDS and V. B. HAWK. (Coop. U. S. D. A.). (*Oregon Sta. Bul.* 431 (1945), pp. 48+, illus. 10).—Feeding tests with sheep of some of the most promising grasses in the grass nursery at Union, Oreg., were made from 1940 to 1944 to determine their value for grazing and for hay. Three palatability classes were set up for each purpose.

It is concluded that orchard grass, tall oatgrass, and meadow fescue should be used as pasture grasses. Timothy should be used for hay, but better grasses such as smooth brome are available. Until more data are available big bluegrass should be handled for hay. Mountain brome and Canada wild-rye are best adapted for short-ley pastures such as sweetclover grass mixture. Tall wheatgrass, Canada wild-rye, and possibly other tall, coarse grasses made the best hay when harvested before blooming.

If a palatable grass for sheep is desired one of the following should be seeded: Hay grasses—Fairway crested wheat, smooth brome, beardless wheatgrass, big bluegrass, meadow foxtail, and timothy; pasture grasses—smooth brome, orchard grass, meadow foxtail, meadow fescue, tall oatgrass, and Standard crested wheat. Some of the grasses that will produce a good yield of palatable feed are: Hay grasses—tall wheatgrass and Canada wild-rye (each cut before bloom), smooth brome, timothy, and big bluegrass; pasture grasses—tall oatgrass, meadow fescue, pubescent wheatgrass, meadow foxtail, and alfa fescue.

**Lamb-feeding experiments,** J. P. WILLMAN, F. B. MORRISON, and E. W. KLOSTERMAN ([*New York*] *Cornell Sta. Bul.* 834 (1946), pp. 62, illus. 8).—The

experiments reported were conducted under feed-lot conditions, with white-faced western ewe and wether lambs, to obtain information of practical value to the lamb feeder. Many of the experiments have been repeated three to five times.

In a study of the value of various protein concentrates, linseed meal, soybean oil meal, whole soybeans, and corn gluten meal were about equal as supplements. The lambs consumed a higher percentage of the roughage offered and were easier to keep on full feed with linseed meal, and this was slightly superior to distillers' corn dried grains (dark) and brewers' dried grains. The results of one experiment (two comparisons) showed distillers' wheat dried grains to be slightly superior to distillers' corn dried grains (dark). In one test, standard wheat middlings proved to be a palatable feed, but 4 out of 10 wethers developed urinary calculi after having been fed wheat middlings for 94 days.

Satisfactory growth and fattening were obtained when enough linseed meal was fed to provide a ration having a protein content of 10 to 10.5 percent (air-dry basis). Rations containing more than 10.5 percent of protein failed to bring significant improvement, but rations containing less than 10 percent total protein resulted in lower rates of gain and higher feed costs.

Lambs fed urea nitrogen as a substitute for all of the linseed-meal nitrogen were difficult to keep on feed and gave unsatisfactory feed-lot performance. As a substitute for two-thirds of the nitrogen, urea failed to show any improvement over the results obtained from a ration containing the same amount of linseed meal but no urea. The feeding of cane molasses and sodium sulfate did not enhance its utilization. Distillers' corn dried grains had a slightly higher value than brewers' dried grains, but both feeds proved satisfactory when fed as protein supplements to a ration of shelled corn and first-cutting alfalfa hay. Distillers' corn dried grains were slightly the superior grains when fed as a substitute for one-third, by weight, of the shelled corn in the ration. As a substitute for one-half of the shelled corn, they had a much lower value than when fed as a substitute for only one-third of the corn.

Shearing feeder lambs during cold weather increased the cost and decreased the rate of gain. "Such factors as yield of wool, the price received for it, and the prices paid for the lambs will determine whether shearing pelts can be produced at a profit."

**Factors affecting rate of gain and their relation to allotment of pigs for feeding trials.** R. M. MIRANDA, C. C. CULBERTSON, and J. L. LUSE. (Iowa Expt. Sta.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 243-250).—The rates of gain by 601 pigs in the Record of Performance work of the Iowa Station were studied to determine the relative importance of breed, litter, sex, initial weight, and previous performance in allotting pigs for feeding trials. It was found that breed and litter must be carefully considered. Differences between sexes were very small although real. "Neglecting sex in the allotment will increase the experimental error only a little, except where carcass characteristics are a prime object of study." The intra-litter correlation between initial weight and rate of gain was 0.24 in these data, indicating that initial weight is not important in allotment when the available pigs do not vary much in weight, and that differences in initial weight might well be handled by analysis of covariance. The intra-litter correlation between gain in a 30-day preliminary period and rate of gain in the final feeding period was 0.32, which is only a little more than was found for initial weight. "The large component of variance for error indicates that, although careful allotment does increase the precision of the experiment, the precision cannot become extreme even by perfect allotment. Further refinements must be sought in the technics of feeding and management if nearly perfect precision is to be attained."

**Effect of feeding level on daily gains of pigs**, F. B. HEADLEY. (Nev. Expt. Sta. coop. U. S. D. A.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 251-255, illus. 1).—This study is based on results obtained from feeding experiments conducted with 95 groups of pigs through a period of 20 yr. The period of experimentation with each group was between weaning age and a finishing weight of approximately 200 lb. All groups of pigs received alfalfa in some form, a grain concentrate, and skim milk. They were divided into four classes: (1) Pasture with no extra protein supplement, (2) pasture with extra protein supplement, (3) dry lot with no extra protein supplement, and (4) dry lot with extra protein supplement. The pigs in class 2 made the most rapid gain and those in class 3 the least rapid gain at any given feeding level.

With all groups included, the regression equation was found to be  $y = 0.2 + 0.367x$ , in which  $y$  represents daily gain and  $x$  the feeding level. The feeding level was found by dividing the average total digestible nutrients fed per day by the mean live weight. It is concluded that the regression equation may be used (1) to indicate the efficiency of any ration that has been used, and (2) as a means of estimating what the daily gain would be at any feeding level.

**Sardine condensed fish solubles and rye pasture for sows during gestation and lactation**, J. L. KRIDER, B. W. FAIRBANKS, R. F. VAN POUCKE, D. E. BECKER, and W. E. CARROLL. (Univ. Ill.). (*Jour. Anim. Sci.*, 5 (1946), No. 3, pp. 256-263, illus. 3).—A basal ration composed of ground yellow corn 67, expeller soybean meal 25, dehydrated alfalfa meal 5, fortified cod-liver oil 0.5, and minerals 2.5 percent, and which contained 17 percent crude protein, was nutritionally inadequate for gestation and lactation under dry-lot conditions. Only 26 percent of the pigs, averaging 17.1 lb., were weaned by sows fed this ration. Deficiency symptoms are described. The addition of either 3 or 6 percent of sardine condensed fish solubles (fresh basis) effectively corrected the deficiency (or deficiencies) of the basal ration. Survivals of pigs so fed to weaning time were 92 and 71 percent with average weights of 31.1 and 33.7 lb., respectively. The pigs in both groups were very growthy and thrifty. The fish solubles was apparently providing supplementary nutrients, probably vitaminlike, which were necessary for satisfactory growth, gestation, and lactation. Fall-seeded rye pasture also proved to be an excellent source of the supplementary nutrients required to correct the inadequacies of the basal ration. Gilts receiving rye pasture weaned 74 percent of their pigs with a weaning weight of 31.9 lb. each.

**Protein and mineral supplements for pigs fed wheat and barley**, R. T. CLARK and R. R. WOODWARD (*Montana Sta. Bul.* 434 (1946), pp. 18).—Experiments are reported in which the efficiency and economy of common protein supplements in wheat and barley rations for swine were tested, as well as the comparative feeding value of locally grown wheat and barley, the value of mineral supplements in swine rations, and the comparative economy of full feeding and limited feeding. The experiments were conducted over a period of 8 yr. with spring pigs both on pasture and in dry lot and with fall pigs in dry lot, and mainly with purebred Duroc Jerseys.

Wheat proved to be superior to barley in promoting rapid gains both in a dry lot and on pasture when these grains were supplemented with a protein feed. Barley was found to be about 93 percent as valuable as wheat. Pigs self-fed wheat and tankage on alfalfa pasture averaged 0.18 lb. more gain per day than pigs fed wheat alone. Skim milk and buttermilk proved to be the most efficient but not necessarily the most economical protein supplements with wheat and barley, both in dry lot and on pasture. "The advisability of using skim milk will in most cases depend on the price ratio between whole milk and cream and the ability of the producer to satisfactorily market whole milk." Soybean oil meal

or flakes as a supplement for pigs fed wheat and barley on pasture produced fair gains, but skim milk and tankage were found superior. A supplemental mixture containing equal parts of tankage, cottonseed oil meal, and linseed oil meal was slightly better than tankage alone but much less efficient than buttermilk in producing rapid and efficient gains. Alfalfa hay alone was unsatisfactory as the only supplement. A basal ration consisting of grain (barley or wheat), tankage, alfalfa, and common salt was not improved by supplementing either with bonemeal, treble superphosphate, lime, or iodine. The addition of bonemeal to a ration of barley and alfalfa for pigs in a dry lot increased significantly the rate and efficiency of gains, but performance of the pigs was unsatisfactory on a ration so low in protein. Comparisons of full-fed with limited-fed rations on pasture over a period of 6 yr. indicated that pigs finish more rapidly but at more expense per unit of gain on full feeding.

**Finishing pigs on rations including barley, oats, corn,** P. G. BEDENBAUGH (*Miss. Farm Res. [Mississippi Sta.], 9 (1946), No. 4, p. 2*).—In a 64-day test, lots of 9 or 10 pigs were grazed on oat pasture plus tankage and cottonseed meal and various ground grains. Lot 1, receiving corn, made average daily gains per head of 2.28 lb.; lot 2, on corn and Delta oats, 2 lb.; lot 3, on corn and Delta barley, 2.14 lb.; lot 4, on Delta oats and barley, 1.84 lb.; and lot 5, on corn, Delta oats, and Delta barley, 2 lb.

**Practical poultry feeding,** L. E. CARD (*Ill. Agr. Col. Ext. Cir. 606 (1946), pp. 23, illus. 2*).—This circular assembles data on the kind and sources of the necessary nutrients and planning the rations. Sample formulas for mash mixtures are included.

**Vitamins for poultry,** F. E. MUSSEHL and C. W. ACKERSON (*Nebraska Sta. Cir. 81 (1946), pp. 8, illus. 3*).—The various vitamins needed by poultry are discussed as to function, probable requirements, sources, and stability, together with starting-mash formulas and specifications for a vitamin concentrate.

**The folic acid requirement of chicks for growth, feathering, and hemoglobin formation,** E. I. ROBERTSON, L. J. DANIEL, F. A. FARMER, L. C. NORRIS, and G. F. HEUSER.—([N. Y.] Cornell Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 62 (1946), No. 2, pp. 97–101, illus. 2).—The folic acid requirement of chicks for growth, feathering, and hemoglobin formation was determined, using a purified diet containing 2.0  $\mu\text{g}$ . of preformed folic acid per 100 gm. of diet. The total folic acid content of the basal diets as determined microbiologically following incubation with chick liver was 5  $\mu\text{g}$ . pr 100 gm. of diet for experiment 1, and 15  $\mu\text{g}$ . for experiments 2 and 3. The following amounts of folic acid, which include the amount in the basal diet, were required for its several functions: For survival to 6 weeks of age, approximately 25  $\mu\text{g}$ . per 100 gm.; for growth and hemoglobin formation at 4 weeks of age, 45  $\mu\text{g}$ .; for growth at 6 weeks, 45  $\mu\text{g}$ ., but for hemoglobin formation at 6 weeks, 35  $\mu\text{g}$ .; and for feathering at 6 weeks of age, not less than 55  $\mu\text{g}$ . per 100 gm. of diet. In these experiments the addition of succinylsulfathiazole at 1 or 2 percent of the diet did not have any effect on growth, feathering, or hemoglobin formation in chicks to 6 weeks of age.

**Effect of diet on the response of chicks to folic acid,** T. D. LUCKEY, P. R. MOORE, C. A. ELVEHJEM, and E. B. HART. (*Wis. Expt. Sta.*). (*Soc. Expt. Biol. and Med. Proc.*, 62 (1946), No. 2, pp. 307–312, illus. 4).—Continuing previous work (E. S. R., 95, p. 549), a study of the effects of dietary constituents upon the activity of synthetic folic acid in chick nutrition indicated that no definite requirement for this compound can be established since the response to a given amount of folic acid depends upon the type of ration used. Folic acid produced the least response with high-fat diets or diets containing glucose, sucrose, or starch as the sole carbohydrate, and the best response with diets containing high

protein, low fat, or corn meal and dextrin as the carbohydrates. Hemoglobin responses were better on diets containing dextrin or corn meal than diets containing other carbohydrates. Feather development could not be correlated with either the amount of folic acid in the diet or the rate of growth of the chicks when low levels of folic acid were included in the diet. Whole-liver substance, when added to a diet containing sucrose as the carbohydrate, gave an increased growth response that could not be attributed to its folic-acid content.

**The influence of autoclaving soybean-oil meal on the availability of cystine and methionine for the chick,** R. J. EVANS and J. MCGINNIS. (Wash. Expt. Sta.). (*Jour. Nutr.*, 31 (1946), No. 4, pp. 449-461).—Using 17 groups of 15 New Hampshire chicks each, in a 4-week experiment, the nutritive value of the proteins of raw soybean-oil meal, as determined by total gain in weight and gain per gram of protein consumed by the chicks, was increased by autoclaving the meal at 100°, 110°, or 120° C. for 30 min. The protein nutritive values were lower when soybean-oil meal was autoclaved at 130° for 30 or 60 min. than when it was autoclaved at 100°–120°. The availability for growing chicks of the methionine and cystine or the organic sulfur in soybean-oil meal was increased by autoclaving the raw meal. The availability of the methionine and cystine or the organic sulfur was not as great when the meals were autoclaved at temperatures above 120° as it was when the meals were autoclaved at 100°, 110°, or 120°. Added methionine increased the growth and feed efficiency on all diets. The addition of 0.2 percent *D,L*-methionine to the basal diet increased the retention by the growing chick of the methionine originally in the unsupplemented diet. The methionine of the soybean-oil meals was retained to a much greater extent than the cystine.

**Corn-and-cob meal versus ground shelled corn in rations for chickens,** D. C. KENNARD and V. D. CHAMBERLIN (*Ohio St. Bimo. Bul.* 241 (1946), pp. 104–113).—Six experiments with growing chickens and five with layers in which corn-and-cob meal was used as a substitute for ground shelled corn are reported.

During the first 8 or 10 weeks, there was little significant difference in mortality, but in general there was a slightly lower rate of growth from the corn-and-cob meal rations. However, the average feed consumption and the pounds of feed per pound of final live weight of birds were favorable to the corn-and-cob meal. Middlings, bran, and ground shelled corn or ground wheat was satisfactorily replaced in one experiment with a high percentage of corn-and-cob meal.

In the experiments with growth of chickens to 18, 20, and 26 weeks, the average gain in weight on the corn-and-cob meal ration was 2.47 lb. and on the shelled corn ration 2.25 lb. The respective pounds of feed per pound of gain were 7.25 and 7.79.

Egg production in the corn-and-cob meal ration averaged 52 percent per bird as compared with 55 percent on the ground shelled corn ration, with feed consumption per dozen eggs averaging 6.62 and 6.30 lb., respectively, and average body weight per bird 5.18 and 5.33 lb. However, a noticeably better condition of plumage was observed among the groups of layers that received the corn-and-cob meal rations, and little or no feather picking and cannibalism was experienced among those groups. It is pointed out that this may often prove of far greater advantage than the disadvantages of slightly less egg production and less body weight of the layers as experienced in these experiments.

**A new ration for growing chickens on range and pasturage,** D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul.* 240 (1946), pp. 57–60, *illus.* 2).—Based upon the previous 5 years' results, experiences, and observations, a new type of ration and method of feeding was designed for raising the station's 2,500 pullets in 1945. The primary object was to avoid the use of needless feed

ingredients and save feed and labor when chickens are raised on range and pasturage. Two rations were devised to supplement a limited range with good pasturage, one supplying 12 percent protein in a whole-grain mixture consisting of whole corn or wheat 60, whole oats 10, coarsely ground corn 15, wheat bran 5, meat scrap 3, soybean oil meal 4, and oystershell or limestone grit, granite or gravel grit, and salt 1 percent each. The other consisted of the same ingredients and amounts, except that 14 percent protein was provided by the use of whole corn or wheat 50, whole oats 10, ground corn 18, wheat bran 6, meat scrap 5, and soybean oil meal 8 percent. The mixture was fed once daily from 3 to 4 p. m. in open-type feeders and in amounts certain to be consumed by about noon of the following day. Practically no difference was noted in the weights of the pullets or feed consumption on the two rations at the end of the 14 weeks' experiment.

**Starting and growing rations for turkeys, R. E. ROBERTS** (*Indiana Sta. Bul.* 517 (1946), pp. 32, illus. 3).—In five trials a starting ration containing 10 percent of dried skim milk and 24.1 percent of protein gave significantly greater increases to 12 weeks of age in only one test for poults of both sexes and another trial for males than a 5 percent skim milk and 22.8 percent protein content. No differences were noted in the efficiency of the two rations or the mortality. Some of the poults started on wire floors developed slipped tendons, a need of additional manganese sulfate being suggested.

In seven experiments with turkeys raised in confinement and one on range, all mash rations comparing 23 or 16 percent of protein were fed ad libitum from 12 weeks to 24, 26, or 27 weeks of age. Weights were practically the same at these ages, although greater gains during the early part of the period were made on the higher protein. In the different trials the birds on the 16-percent protein ration consumed approximately 10 to 20 percent less feed than those on the 23-percent protein ration.

Limited data obtained from feeding each ration to one lot of turkeys each on range and in confinement showed that on the 23-percent protein ration the growth on range was practically the same as in confinement, while on the 16-percent ration the males on range were the heavier throughout the growing period, and the females to 24 weeks of age. On both rations the birds on range consumed more feed, exclusive of that supplied by the range, than those in confinement.

In those experiments in which separate feed records were obtained, the females consumed only 64 to 80 percent as much feed as the males. Due to their greater gains, however, the males used only 83 to 92 percent as much feed per pound of gain as the females. There was no difference in mortality which could be attributed to the rations fed.

In two experiments with turkeys raised in complete confinement and one with turkeys on range, two all-mash rations, each containing 16 percent protein, were fed ad libitum from 12 to 27, 28, or 30 weeks. One ration contained 2.5 percent dried skim milk, while in the other the milk was replaced by 2.5 percent soybean oil meal. In no case was there any significant difference in the comparable weights of either sex on the two rations, in the feed efficiency, or in viability.

## DAIRY FARMING—DAIRYING

**Dairy Research Digest [June and September 1946]** (*Dairy Res. Digest* [Louisiana Sta.], 4 (1946), Nos. 2, pp. 4; 3, pp. 4).—In addition to items noted elsewhere in this issue or previously, No. 2 contains Better Dallis Grass Is Selected, by C. R. Owen (p. 3). No. 3 contains Clean Pasture Proved Good for Young Calves, by G. D. Miller and D. M. Seath (p. 1); Heat Tolerance of Jerseys Compared to Holsteins, by D. M. Seath and G. D. Miller (p. 1); Dehydrated Sweet

Potatoes Are Valuable in Dairy Ration, by D. M. Seath, L. L. Rusoff, and G. D. Miller (p. 2); and Johnson Grass Boosts Milk Yields, by D. M. Seath and D. M. Johns (p. 2).

**Simple vs. complex grain mixtures in dairy rations, III, IV** (*Ohio Sta. Bmo. Buls.* 240 (1946), pp. 64-73; 241 (1946), pp. 97-99).

III. *The effect of substituting ground ear corn for ground shelled corn in the simple grain mixture*, C. F. Monroe and W. E. Krauss.—Continuing this series (E. S. R., 95, p. 381), reversal trials were conducted using 2 periods of 50 days each and 70 Holstein cows. A simple grain mixture containing ground ear corn was compared with one containing ground shelled corn. Both mixtures contained soybean oil meal, 2.5 percent more being added to the ground ear corn mixture in order to equalize the protein content of the two mixtures. Comparable amounts of salt, steamed bonemeal, and limestone were used, together with corn silage and legume mixed hay.

Milk and butterfat production was a little higher on the ground shelled corn mixture; in terms of 4 percent milk, the production on the latter amounting to 98.83, 98.29, and 98.62 percent of the former, in the three trials, respectively. An analysis of the production following the reversing of the feeding at the end of the first period confirmed these findings. There were no marked differences in live-weight gains on the two mixtures, and the butterfat tests were apparently not affected.

It is concluded that the simple grain mixture containing ear corn and reinforced with extra soybean oil meal may be expected to yield results within 2 percent as satisfactory as a comparable mixture containing ground shelled corn, and that the common practice of feeding ground ear corn rather than ground shelled corn to dairy cows is justified.

IV. *Heifer calves raised for replacements and weals for slaughter*, W. E. KRAUSS and C. F. MONROE.—Sixty-five heifer calves were used in a 6 months' comparison and 58 bull calves were raised to slaughtering age at 9 weeks. The calves did as well when fed, in addition to milk, a simple grain mixture containing equal parts by weight of whole shelled corn and whole oats as when a complex mixture containing ground corn, ground oats, bran, linseed oil meal, soybean oil meal, and skim milk powder was fed. The daily gains per head for the simple and complex mixtures were 1.2 and 1.23 lb. for the heifer calves and 0.86 and 0.81 lb. for the bull calves.

"When calves are raised according to the whole milk-skim milk plan, simple combinations of whole or coarsely ground cereal grains should constitute a satisfactory grain mixture."

**Wild yellow mustard seed and fanweed seed as concentrate feeds for milking cows**, J. O. TRETSVEN and J. A. NELSON (*Montana Sta. Bul.* 435 (1946), pp. 11).—Analysis of a sample of wild mustard seed containing 14 percent of sweetclover and 2.22 percent of other seeds and inert material showed a composition of moisture 8, crude protein 23.37, ether extract 30.17, nitrogen-free extract and ash 27.51, and crude fiber 10.95 percent. For a fanweed seed sample containing 6.11 percent of green foxtail and 4.48 percent of other seeds and inert material, the corresponding analysis was 11.10, 19.29, 24.62, 27.74, and 17.25 percent. In two feeding trials of 56 and 70 days, respectively, with 5 or 6 cows in each lot, there was an average daily production of milk per cow of 45.44 lb. on an 8 percent wild mustard seed ration, 43.70 lb. on an 8 percent fanweed seed ration, and 43.22 lb. on an 8 percent soybean oil meal ration. The corresponding daily yields of butterfat were 1.73, 1.61, and 1.63 lb. In a third trial with 8 cows in each lot and an 84-day period, the average daily production was 26.75 lb. of milk and 1.21 lb. of butterfat on a ration containing 10 percent of ground wild yellow mustard seed, and 24.95 lb. of milk and 1.12

lb. of butterfat for the lot receiving 10 percent additional ground barley in place of the mustard seed. It is concluded that the ground wild yellow mustard seed has a feeding value slightly above that of soybean oil meal and that the ground fanweed seed is of about equal value with the soybean oil meal. Both seeds can be fed immediately after milking without detrimental effect on the flavor of the milk, cream, and butter produced.

**Clipping vs. grazing by dairy heifers as means of estimating yield of bluegrass pastures**, H. B. MORRISON and F. ELY. (Ky. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 7, pp. 393-405, illus. 6).—Yield of a Kentucky bluegrass pasture of 11.6 acres in terms of total digestible nutrients per acre was calculated from clipping with a lawnmower and from grazing with a total of 116 dairy heifers during 5 seasons, 1940-1944, inclusive, ranging from 168 to 210 days in length. The average calculated yield from clipping was 68.5 percent of that from grazing. The trends of the curves representing calculated yield obtained by clipping and grazing with heifers were in general quite similar, although a pronounced change in yield usually occurred in the grazing curve 2 to 3 weeks later than in the clipping curve. The data obtained indicated that the clipping method of measurement may be used in a preliminary way to evaluate variables in experimental management of Kentucky bluegrass pastures.

**The relative importance of high temperature and high humidity as factors influencing respiration rate, body temperature, and pulse rate of dairy cows**, D. M. SEATH and G. D. MILLER. (La. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 7, pp. 465-472, illus. 3).—Continuing earlier studies (E. S. R., 95, p. 380), observations were made of 36 Holstein and 16 Jersey milking cows during the summer of 1944 and of 41 Holsteins and 27 Jerseys in 1945.

Changes in air temperature appeared to be the major cause of increases in body temperature and respiration rate of milking cows. Multiple regression equations indicated that 1° increase in air temperature was responsible for from 13 to 15 times as much increase in body temperature as was an increase of 1 percent in humidity. Likewise, 1° change in air temperature caused from 41 to 43 times as much influence on respiration rate as did 1 percent change in humidity. On a partial correlation basis (air temperature held constant) an increase in humidity slightly lowered respiration rate. The  $r$  values were -0.06 and -0.02. Partial correlations between air temperature and body temperature (humidity held constant) were 0.674 and 0.534. Pulse rates were less affected by either air temperature or relative humidity than was body temperature. Air temperature and pulse rate measured independently of humidity gave  $r$  values of 0.195 and 0.159. Humidity and pulse rate (with air temperature constant) gave a value of -0.05 for one year and 0.07 for the other, thus leaving a question as to its real relationship.

**Variations in the live weight of dairy cattle**, N. N. ALLEN (*Vermont Sta. Bul.* 534 (1946), pp. 12, illus. 2).—Dairy cattle were confined to stalls mounted on scales for 10-day periods, and weighed at half-hour intervals without disturbing their usual routine. Records were kept of all measurable factors which might contribute to a change of weight and the average trend of the weight during the day and the range of the variations from day to day are shown graphically.

The animals showed very striking uniformity in the times at which the maximum, minimum, and mean weights for the day were reached. The five milking cows drank more frequently and consumed much more water than did five dry cows and heifers. They also eliminated more feces and urine and had greater insensible loss, and their weights fluctuated over a wider range. The nonmilking animals were more active and lay down and got up more frequently.

It is suggested that in any experiments in which live weights are determined, careful thought be given to the purpose for which the weights are to be used. The time of day at which the animals are weighed should be planned accordingly.

**Wanted—more long lived cows, E. J. PERRY.** (N. J. Expt. Sta.). (*Guernsey Breeders' Jour.*, 69 (1946), No. 2, pp. 131-133).—This is a statement of the advantages of retaining dairy cows in service for relatively long periods.

**Time required for making flavor judgments of milk, G. M. TROUT.** (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 7, pp. 415-419, illus. 1).—The average time required to make flavor judgment on 2,262 individual samples of milk was found to be 7.2 sec. per sample, ranging from a low of 2.9 sec. for "salty" milk to 8.2 sec. for "excellent" milk, which invariably required longer judgment time than did off-flavor milk. The judgment times for "cheesy," "high-acid," "rancid," "flat," and "oxidized" milks were between these extremes and were in the above order. Milks having off-flavors of slight intensity required considerably longer judgment time than did those having pronouncedly intense off-flavors.

**Raw milk contamination in homogenized milk, A. V. MOORE and G. M. TROUT.** (Mich. Expt. Sta.). (*Canad. Dairy and Ice Cream Jour.*, 25 (1946), No. 7, pp. 33-34, 64, illus. 3).—Tests are reported with a high-quality milk pasteurized at 143° F. for 30 min. and homogenized at 2,500 lb. pressure, contaminated with raw mixed milk of good quality. It is concluded that the phosphatase test can detect a 0.5 percent contamination. The level of contamination detectable by organoleptic examination depended largely on the length of the storage period, in general needing at least 4 percent of raw milk with only 24 hours' storage and in no case detecting 0.1 percent when mixtures were held 7 days at 40°.

**Heat resistant bacteria from an unclean milking machine invade the udder of the cow, C. S. and H. S. BRYAN and K. MASON.** (Mich. Expt. Sta.). (*Milk Plant Mo.*, 35 (1946), No. 8, pp. 30-32).—An instance is cited in which an unclean milking machine contributed heat-resistant bacteria to the milk both directly during the milking process and indirectly by having served to inoculate the cow's udders with these bacteria. The cows rid themselves of the heat resistant bacteria in periods varying from 1 to 4 mo. after the milk equipment was properly cleaned and sanitized. During this same period the standard plate bacteria count of the properly pasteurized milk of this dairy decreased from as much as 2,500,000 to its previously normal level of 10,000 to 25,000.

**Quality control of milk for manufacturing purposes, J. C. HENING.** (*Milk Plant Mo.*, 35 (1946), No. 6, pp. 28, 48-56, illus. 2).—This is an account of the classes of milk established by the Food and Container Institute for the Armed Forces and of the work of the mobile laboratories in carrying on tests of milks used for manufactured products.

**Measuring detergency functions as affected by various detergents and procedures against milk films by application of a mechanical washing apparatus, J. M. JENSEN.** (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 7, pp. 453-463, illus. 6).—Detergency studies were made on various types of washing products by washing raw milk films from glass surfaces by a devised mechanical apparatus and measuring result in terms of light transmission by use of a Cenco-Sheard spectrophotometer. An appreciable difference was observed in detergency as affected by detergent material and variations in washing procedure that was measured by light transmission readings. Highest detergency values were secured with solutions prepared of near-neutral wetting agent and metaphosphate mixtures. Next in order of detergency were slightly alkaline wetting agent detergent, alkaline salts containing wetting agent, alkaline salts

containing metaphosphate, and acid detergent solution which gave lowest and entirely inadequate detergency. Prerinsing effects demonstrated depressive detergency action with both hard and soft water with all detergents except acid. Better detergency was secured with soft water than with hard water. Highly improved detergency was attained when prerinsing with water containing metaphosphate in slight excess of that required for sequestration of water hardness. After rinsing effects demonstrated improved detergency with alkaline detergents when hard and soft water were used at 150° F. Depressed detergency occurred with acid, wetting agent, and wetting agent plus metaphosphate detergents. However, soft water for final rinse gave better results than hard water. When wetting agent-metaphosphate detergent was used and the final rinse contained 0.10 and 0.15 percent metaphosphate in water containing 300 to 320 p. p. m. hardness, high light-transmission readings were maintained throughout repeated washing trials. Highest and practically complete detergency as measured by light transmission occurred when 0.10 and 0.15 percent wetting agent-metaphosphate detergents were used in the final rinse.

The activity of penicillin in relation to bacterial spores and the preservation of milk, H. R. CURRAN and F. R. EVANS. (U. S. D. A.). (*Jour. Bact.*, 52 (1946), No. 1, pp. 89-98).—In their reaction to penicillin, *Bacillus cereus*, *B. mycoides*, *B. albolactis*, and *B. metiens* were relatively resistant; penicillin was thus not an effective preserving agent except in concentrations that would be impracticable. The remaining 13 species tested were relatively susceptible to penicillin as manifested by strong sporicidal or prolonged sporistatic activity in a drug concentration of 5 $\mu$  per cubic centimeter; this concentration sterilized many of the cultures. Penicillin at five units per cubic centimeter greatly delayed but did not prevent spoilage by *Clostridium botulinum* and another unidentified anaerobic species; in the former case, toxin formation accompanied spoilage. The sporistatic period varied with spore concentration and penicillin level. An extremely small proportion of the spores of *C. botulinum* proved highly resistant to the sporistatic action of penicillin. The evidence suggests that all spore cultures contain spores susceptible to penicillin, the species differing in the relative proportion of resistant and sensitive cells. It is concluded that penicillin has no application in the preservation of food; in combination with mild heating, it might have utility as a preservative or spoilage-delaying agent in certain nonfood materials.

The activity of streptomycin in relation to bacterial spores and the preservation of milk, H. R. CURRAN and F. R. EVANS. (U. S. D. A.). (*Jour. Bact.*, 52 (1946), No. 1, p. 142).—The findings presented in this note indicate that streptomycin in ordinary concentrations has a very limited activity against bacterial spores.

A method for producing a dairy spread, K. G. WECKEL. (Univ. Wis.). (*Milk Plant Mo.*, 35 (1946), No. 9, pp. 24-25, illus. 3).—A simplified procedure said to be usable in any modern city market milk plant is described. The product, distributed under the term "Dyne" as the collective trademark of the Wisconsin Alumni Research Foundation, has a butterfat content of 28 percent and a milk-solids-not-fat content of 19 percent. It is pointed out that the food regulations of many States do not provide for a product of this character.

The dual use of the Vacreator for condensing milk and pasteurizing ice cream mix, G. H. WILSTER (*Oregon Sta. Bul.* 430 (1945), pp. 66+, illus. 13; *abs. in Amer. Butter Rev.*, 8 (1946), No. 9, pp. 28, 30, 32, illus. 2).—An extension of the Vacreator process of high-temperature vacuum pasteurization (E. S. R., 84, p. 387) to condensing milk for ice cream mix is described. A simple, practical, and inexpensive method of condensing skim milk to the concentration desired for ice

cream mix, using the Vacreator without any mechanical change as a milk condenser, was devised by which condensed milk of very satisfactory quality was obtained. Condensing the complete mix, using cream and either whole milk or skim milk as sources of fat and milk solids-not-fat, was found to be possible but less convenient and satisfactory.

The quality of the ice cream made when the mix was homogenized, vacuum pasteurized with a Vacreator at 198° F., and immediately cooled was superior to that of ice cream made when the mix was pasteurized by the vat-holding method (160° for 30 min.), homogenized, and cooled. The bacterial content of the homogenized, vacreated, cooled ice cream mix was very low. Negative phosphatase tests were always obtained.

Ice cream of highly satisfactory flavor, body, and texture, and melt-down characteristic was made when the required skim milk was condensed by the Vacreator to the density desired; the required other mix ingredients were added to the condensed skim milk; and the mix was homogenized vacuum pasteurized, and immediately cooled. Whole milk was also successfully condensed, and the ice cream made from the mix with which condensed whole milk was used had a superior flavor to that made from mix with which condensed skim milk was used.

The method of condensing milk with the Vacreator is fully described. Directions for determining the density of the condensed milk and for its subsequent standardization are also given.

**Powdered mix**, S. D. [i. e. T.] COULTER. (Univ. Minn.). (*Ice Cream Trade Jour.*, 42 (1946), No. 5, pp. 42, 62).—Progress in the development of dry ice cream mix is summarized.

**The use of fruit purees in ice cream**, C. L. BEDFORD. (Wash. State Col.). (*Ice Cream Trade Jour.*, 42 (1946), No. 5, pp. 44, 80).—This is a discussion of the use of unsweetened fruit purees, frozen sweetened pulp fruit, and pectinized or gelatinized purees.

## VETERINARY MEDICINE

**Some hereditary abnormalities of domestic animals**, F. B. HURT. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 2, pp. 180-194, illus. 6).

**Three new *Salmonella* types: *S. richmond*, *S. daytona*, and *S. tallahassee***, A. B. MORAN and P. R. EDWARDS. (Ky. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 62 (1946), No. 2, pp. 294-296).—Three new *Salmonella* types were described: *S. richmond* (VI,VII:y-1,2,3 . . .), *S. daytona* (VI,VII:k-1,6 . . .), and *S. tallahassee* (VI,VIII:z<sub>1</sub>, z<sub>2</sub> . . .). Attention was directed to the necessity of redefining factors z<sub>2</sub> and z<sub>24</sub> since *S. tallahassee* was agglutinated by both serums as they previously were prepared.

**Flagella and flagellar antigens in "non-motile" *Salmonella* cultures**, P. R. EDWARDS, A. B. MORAN, and D. W. BRUNER. (Ky. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 62 (1946), No. 2, pp. 296-298, illus. 2).—Two apparently nonmotile strains possessed well-developed flagella and flagellar antigens. One of the types (III,XV:e,h) eventually yielded motile elements after serial transfer in semisolid medium. The other (*S. sandiego*) gave no evidence of motility after similar treatment.

**A note on *Salmonella abortus-equi* infection in man**, D. W. BRUNER. (Ky. Expt. Sta.). (*Jour. Bact.*, 52 (1946), No. 1, p. 147).—A note on an outbreak of food poisoning in Italy from horse meat infected with *S. abortus-equi*.

**Newer drugs against bacterial infections**, B. VASSEL (*North Dakota Sta. Cir.* 73 (1946), pp. 16, illus. 1).—This address deals especially with the sulfonamides and penicillin and their therapy.

Some aspects of the pharmacology of the sulfonamides and penicillin, L. M. JONES. (Iowa State Col.). (*North Amer. Vet.*, 27 (1946), No. 7, pp. 422-425, 434).—This is a discussion of methods of administration, toxic reactions, dosage, limitations, and other aspects of use.

Livestock poisoning caused by sulphur in combination with protein concentrates, J. W. TOBISKA and R. JENSEN (*Colo. A & M News*, 1 (1946), No. 3, p. 5).—Following a heavy mortality when pellets of cotton cake, linseed meal, and sulfur were fed to fattening lambs and accidentally consumed by cattle, laboratory tests were carried on with rabbits and sheep. When the pellets were separated into sulfur and protein fractions, neither constituent would kill rabbits, but when recombined the mixture was poisonous. A new mixture of 44 percent each of cotton cake and linseed meal and 12 percent of sulfur flour proved as toxic to rabbits as the original mixture. In paired experiments with sheep no deaths followed the separate feeding of the protein concentrates and sulfur, but the tests with graduated amounts of the mixture indicated that a dosage of 10 gm. per kilogram of body weight approximates the minimum lethal dose for sheep.

The use of DDT in medicine—a review, C. WESTERFIELD. (Ky. Expt. Sta.). (*Vet. Med.*, 41 (1946), No. 10, pp. 355-360, illus. 2).—This review (34 references) deals with the mode of action, limitations, toxicity, and uses of DDT.

Toxicity of alpha naphthyl thiourea for chickens and pigs, W. A. ANDERSON and C. P. RICHTER. (U. S. D. A. et al.). (*Vet. Med.*, 41 (1946), No. 9, pp. 302-303, illus. 1).—Observations are reported of poisoning of young chicks and pigs by the rodenticide ANTU, but apparently less toxicity in older birds. It is regarded as unlikely that under ordinary poisoning operations for rats on farms either young chicks or pigs would be exposed to lethal amounts of ANTU, but care should be exercised in the disposal of poisoned grain and bait. A possible toxicity of ANTU to human beings is also suggested.

Progress in the control of brucellosis (Bang's disease) in domestic animals, W. L. BOYD. (Univ. Minn.). (*Minn. Med.*, 29 (1946), No. 7, pp. 681-683).—A practical statement of present knowledge.

The blood picture in cases of retained fetal membranes in cattle, G. R. MOORE. (Kans. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 109 (1946), No. 832, pp. 39-45, illus. 1).—Total cell and differential leucocyte counts were made on 100 cases of retained placenta. It was found that there was a marked decrease in the mature neutrophils, beginning within 24 hr. after parturition and reaching its low point at about 72 hr. after parturition and then returning to nearly the normal level at 196 hr. following parturition. This decrease was accompanied by an increase in immature neutrophils and the appearance of toxic granulation, indicating a degenerative "shift to the left." It was suggested that these changes were due to the absorption of toxins from the decomposing placentas.

Ketosis like yet unlike milk fever, J. C. SHAW. (Univ. Md.). (*Jersey Bul.*, 65 (1946), No. 9, pp. 664-665, 722-728, illus. 3).—Ketosis and milk fever are differentiated, data are graphically presented on the blood picture in experimental ketosis, and the dextrose treatment is described.

Penicillin therapy in mastitis, S. D. JOHNSON and M. G. FINCHER. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 2, pp. 138-158, illus. 1).—Details of the study and treatment with penicillin of 213 cows with 316 mastitis quarters in New York State are reported.

It is concluded that results have been good but impaired by the use of incorrect dosages, infrequency of infusion, and the seriousness of some of the cases. The optimum dosage appears to be 25,000 to 100,000 units in 10 to 50 cc. of sterile distilled water given at least three times. The herds given these treatments were uniformly benefited and no harmful results were observed.

**Dosages of penicillin for *Streptococcus agalactiae* mastitis,** J. J. PORTER, H. M. CAMPBELL, A. F. WEBER, and T. F. REUTNER. (Wis. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 109 (1946), No. 832, pp. 60-64).—Two hundred forty quarters of 120 cows infected with *S. agalactiae* were assigned a dosage of penicillin (sodium) or utilized as untreated controls.

When 30 quarters of 15 cows were treated with 1,000 units, cures in from 1 to 3 treatments were obtained in 14 of the quarters; 5,000 units, 15 quarters; 10,000 units, 18 quarters; 15,000 units, 22 quarters; 30,000 units, 21 quarters; 50,000 units, 19 quarters; and 100,000 units, 22 quarters. In all of the untreated controls, none of the quarters became free of the infection.

The stage of lactation had no apparent effect on the curative process of the treatment. Quarters producing highly abnormal milk at the time of treatment were rarely freed of infection, but in almost every instance the macroscopic appearance of the milk was greatly improved. After the milk returned to normal consistency, which occurred after one to six milkings, no unfavorable change was noted in the production of milk.

**Diseases of calves,** D. H. UDALL. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 2, pp. 170-180).—This discussion refers especially to diarrhea and pneumonia in calves in New York State, and covers an experience of about 25 yr. It is concluded that sulfathalidine is highly useful in the treatment of diarrhea. Calves raised on nurse cows in pens open on one side are almost completely protected against pneumonia. It is suggested that, in general, diarrhea and pneumonia are independent diseases, affecting calves in different age groups, and that the term "pneumoenteritis" has a very limited application.

**Lantana poisoning in cattle,** D. A. SANDERS. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 109 (1946), No. 833, pp. 139-141, illus. 2).—Investigations of a peculiar and often fatal condition affecting both beef and dairy cattle in many areas of the State indicated the cause to be plant poisoning associated with photosensitization resulting from eating the ornamental shrub *L. camara*, which in many sections has escaped from cultivation.

Experimental feedings made with the plant show that amounts as small as  $\frac{3}{4}$  to 1 lb. of the mature frosted and dried leaves are sufficient to produce typical symptoms of chronic poisoning of 5 weeks' duration in animals weighing 400 lbs. that are confined in the sunlight.

Cattle which have become familiar with the plant by long association do not usually eat it, but its removal from unfamiliar locations or fencing it off is advocated. Direct sunlight should be avoided with affected animals.

**Control of enterotoxemia (pulpy kidney disease) in lambs by the use of alum precipitated toxoid,** O. H. MUTH and D. R. MORRILL. (Oreg. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 24, pp. 355-357).—An alum precipitated toxoid was prepared from *Clostridium perfringens* type D, which, when injected into 12 5-month-old lambs, produced a higher antitoxic titer than in 6 lambs given the usual 5-cc. dose of antiserum. In extensive field trials, injections of alum precipitated toxoid apparently reduced enterotoxemia losses and appeared to be a promising method.

**Vitamin E prevents and cures the "stiff-lamb disease,"** J. P. WILLMAN, J. K. LOOSLI, S. A. ASDELL, F. B. MORRISON, and P. OLAFSON. (Cornell Univ.). (*Cornell Vet.*, 36 (1946), No. 2, pp. 200-204).—Experiments in 1945 are reported, repeating those previously noted (E. S. R., 93, p. 328). No death losses resulted in 17 stiff lambs given the disodium salt of *d,l*- $\alpha$ -tocopherol phosphoric acid ester either subcutaneously or as a drench or *d,l*- $\alpha$ -tocopherol acetate in olive oil, while of 8 untreated lambs 3 died and 2 were destroyed in a helpless condition.

**Feeding sulphur to lambs cuts gains but prevents "overeating" death losses.** A. L. ESPLIN, A. W. DEEM, and W. E. CONNELL (*Colo. A & M News*, 1 (1946), No. 3, pp. 6-7, illus. 11).—In a test carried on to evaluate the effect of sulfur on death loss from enterotoxemia, four lots of 500 70-lb. lambs each were fed a grain mixture of corn and barley 1: 1, whole alfalfa hay, and salt. Two lots were self-fed and two hand-fed the grain mixture, with one lot in each group also receiving 2 percent of sulfur in the grain mixture.

The average daily grain consumption was smaller in the lots receiving sulfur. Their average daily gains were 0.35 and 0.31 lb. for those self-fed and hand-fed, respectively, and compared with 0.4 and 0.33 for the control lots. However, the death loss was only 1.8 and 1.0 percent in the self-fed and hand-fed lots receiving sulfur, as compared with 6.6 and 9.6 percent for the controls, and the sulfur-fed lambs showed 68 and 46 ct. more profit per head. No effect on the flavor of the meat was noted.

**Lead arsenate relieves scouring in lambs due to tapeworm infestation.** R. T. HABERMANN and F. N. CARLSON. (U. S. D. A., S. Dak. Expt. Sta., et al.). (*Vet. Med.*, 41 (1946), No. 9, pp. 306-310, illus. 4).—Observations at Newell, S. Dak., indicated that tapeworms are an important cause of scouring in lambs in the area. In trials with lead arsenate on 26 tapeworm-infested lambs, doses of 1 gm. of the drug removed, safely and effectively, a high percentage of *Moniezia expansa*, and the treatment proved remarkably effective in curing scouring. However, none of the fringed tapeworms (*Thysanosoma actinoides*) which were present in 6 of the lambs were removed by the lead arsenate treatment.

**Treatment of filarial dermatosis of sheep with antimony compounds.** H. E. KEMPER and I. H. ROBERTS. (U. S. D. A.). (*Amer. Jour. Vet. Res.* 7 (1946), No. 24, pp. 350-354).—Tartar emetic in combination with emetine hydrochloride, tartar emetic alone, tartar emetic with glucose, Trichicide, anthiomaline, and fuadin were tested on a limited basis for their effectiveness in curing filarial dermatosis of 15 sheep. Tartar emetic with emetine hydrochloride, and tartar emetic alone, produced complete healing of characteristic lesions of this parasitism, but abscess formations at site of injections were not uncommon. Tartar emetic with glucose, and Trichicide, a product containing sodium antimony tartrate, trypan blue, and phenol, brought about recovery without untoward sequels. To effect healing, all the above preparations required from 6 to 8 intravenous or intramuscular injections. However, preliminary tests with anthiomaline and fuadin showed distinct promise of bringing about uncomplicated recovery with single injections of large doses.

**Hexachlorethane-bentonite suspension for the removal of the common liver fluke, *Fasciola hepatica*, from sheep.** O. W. OLSEN. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 7 (1946), No. 24, pp. 358-364).—Hexachloroethane prepared as a suspension with bentonite and water proved to be an effective fasciolicide for sheep when given as a drench. Of 110 infected sheep given 30 cc. of suspension (15 gm. of hexachloroethane), 104 did not show eggs of the liver fluke in the feces following a single treatment. Little change occurred in the number of eggs of 3 animals whose original counts were 16 per gram or less. The remaining 3 showed only 4 eggs per gram as compared with a premedication count of 60 to 112. There was even greater effectiveness when administered at a dose rate of 60 cc. (30 gm. of hexachloroethane) per animal.

Immature flukes were more resistant to hexachloroethane than mature flukes, suggesting the importance of treating during the season when the fewest immature flukes are present in the body of the host. In these tests, hexachloroethane was well tolerated in doses far in excess of the amounts required to remove the flukes. However, a footnote is appended to the paper which states that "since this paper

was submitted for publication, some instances of intoxication and death, for which there is no obvious explanation, occurred in one locality outside the coastal area of Texas following treatment of sheep with hexachloroethane, as well as with a standard dose of carbon tetrachloride."

The life history of *Ostertagia ostertagi*, W. L. THRELKELD (*Virginia Sta. Tech. Bul.* 100 (1946), pp. 14, illus. 31).—This study of the preparasitic stages of the development of *O. ostertagi* and results obtained from oral administrations of the infective larvae of this species revealed a life history similar in many aspects to the developmental stages of *O. circumcincta* (E. S. R., 71, p. 388). Adult worms incubated at 37.5° C. in Ringer's solution deposited eggs 70 $\mu$ –80 $\mu$  long by 40 $\mu$ –45 $\mu$  wide, which hatched in 12 hr. after deposition. Eggs obtained from freshly drawn feces and incubated at room temperature hatched in 24 hr. First-stage larva ranged in length from 300 $\mu$  to 450 $\mu$ . The first ecdysis occurred on the second day after the emergence of the first-stage larvae. Typical second-stage larvae appeared on the third day. They averaged about 800 $\mu$  in length and possessed a typical rhabditiform oesophagus. No second ecdysis of second-stage larvae was observed. Third-stage larvae appeared on the fifth and sixth days. The length of these larvae was from 800 $\mu$  to 900 $\mu$ . "Forty-eight hr. after the oral administration of the third-stage or infective larvae to calves, these larvae are found in the abomasum unchanged as to length or appearance. At 72 hr., the larvae are undergoing ecdysis and some have penetrated the mucosa. At this stage sex differentiation could not be determined. Larvae found in the mucosa at 96 hr. had completed their second ecdysis and were in the second parasitic stage. Sex differentiation could be made at this age." Photomicrographs at magnification X100 of larvae in the walls of the mucosa indicated that after the ninety-sixth hour the larvae remain sheathed until the tenth day after oral administration. Larvae found free in the abomasum at 10 days were sheathed or have undergone their final ecdysis. Larvae at 15 days were in the immature adult stage and were found free or attached to the mucosa and some were found coiled within nodules or lesions within the mucosa. On the twenty-first day following the oral administration of infective larvae, mature male and female worms were present in the abomasum. The uteri of the female contained 20 to 30 eggs in an advanced degree of development. On the twenty-third day eggs appeared in the feces. While the blastomeres could not be counted with accuracy, it appeared that the majority are in the 16- to 32-cell stage. Some eggs displayed greater development, and in a few worms immature motile larvae could be observed. In calves exposed for 2 weeks to infective *O. ostertagi* larvae in paddocks and then maintained indoors for 2 and 3 weeks, immature adults were found coiled within the mucosa. A few were found between the adjacent walls of the folds of the fundus. The posterior section of adult females were found in the lesions in the mucosa. It appeared that in some cases eggs were in process of deposition as they were in the vagina and the oviducts. Capsules containing eggs (presumably *O. ostertagi* as no extraneous species were found) were observed within the walls of the mucosa.

Parasites and parasitic diseases of swine, H. C. H. KERNEKAMP. (Minn. Expt. Sta.). (*Vet. Med.*, 41 (1946), No. 9, pp. 315–318, illus. 1).—This discussion deals especially with ascariasis and pulmonary strongylosis.

Preliminary report on the propagation of hog cholera virus in vitro, W. H. BOYNTON. (Univ. Calif.). (*Vet. Med.*, 41 (1946), No. 10, pp. 346–347, illus. 1).—A modification of the serum ultrafiltrate method of tissue culture and propagation of viruses developed by H. S. Simms and M. Sanders<sup>4</sup> is described.

<sup>4</sup> Arch. Pathol., 33 (1942), No. 5, pp. 619–635, illus. 3.

**Observations regarding *Salmonella choleraesuis* (var. *kunzendorf*) septicemia in swine**, L. SEGHERI. (Mont. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 109 (1946), No. 833, pp. 134-137.)—Observations of septicemic salmonellosis involving some 400 pigs on six premises are reported. The onset of the disease was acute, and the cardinal symptoms were a marked rise in temperature, posterior incoordination, and weakness. The mortality was not great and ceased of its own accord after a small percentage of the pigs had died. Macroscopically, the lesions were indistinguishable from those ascribed to hog cholera. However, *S. choleraesuis* was repeatedly recovered from pigs dying of this disease, whereas bacteria-free filtrates prepared from blood and other organs when injected into cholera-susceptible pigs failed to produce a reaction.

**Pig typhus (*Salmonellosis suis*)**, L. VAN ES (*Nebraska Sta. Res. Bull.* 147 (1946), pp. 28, illus. 9.)—This discussion deals with the infectious necrotic enteritis caused by *Salmonella suispestifer*, taking up its etiology, epizootiology, clinical manifestations, pathologic anatomy, diagnosis, economic importance, meat poisoning in man, therapy, and prophylaxis. A list of 105 references is appended.

**The incidence of blood spots in eggs and its relation to first year mortality**, I. M. LERNER. (Univ. Calif.) (*Poultry Sci.*, 25 (1946), No. 4, pp. 392-394.)—Two series of Single-Comb White Leghorn pullets hatched in consecutive years were studied. The incidence of blood spots in their eggs after adjustment for hereditary differences and season was in general higher in birds which survived the first laying year than in those which died.

**Toxicity of choline in the diet of growing chickens**, V. H. MELASS, P. B. PEARSON, and R. M. SHERWOOD. (Tex. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 62 (1946), No. 2, pp. 174-176.)—Various levels of choline chloride were added to rations fed to growing chickens. The addition of 1, 2, and 4 percent reduced the rate of gain by about 12, 13.8, and 23.8 percent, respectively. As much as 4 percent of choline chloride added to the diet produced no toxic manifestations other than retarded growth.

**Toxicity of sodium chloride solution for baby chicks**, E. R. DOLL, F. E. HULL, and W. M. INSKO, JR. (Ky. Expt. Sta.). (*Vet. Med.*, 41 (1946), No. 10, pp. 361-363.)—Water from a saline or "soda-water" well containing chlorine equivalent to 0.54 percent sodium chloride and sodium equivalent to 0.7+ percent of sodium chloride was found to be toxic for young chicks. Experimental use of solution of C. P. NaCl in concentration of 0.5 percent and 0.9 percent as drinking water produced disease in day-old chicks identical with that resulting from use of the well water. Clinical evidence of toxicity was not observed in chicks receiving 0.25 percent NaCl during 3- and 4-week trials. Concentrations of 1.5 and 2.0 percent NaCl in the water caused acute toxicity with nervous disturbances, including somnolence, convulsions, incoordination, and inability to stand.

**Effect of sulfaguanidine on caecal coccidiosis**, K. C. SEEGER and A. E. TOMHAVE (*Delaware Sta. Bul.* 260 (1946), pp. 19.)—The effectiveness of sulfaguanidine in controlling losses and establishing immunity from cecal coccidiosis in artificially inoculated chicks was demonstrated in a group of four experiments. Similar results were obtained when this inoculation-treatment procedure was applied to two commercial flocks of broilers. When the infection with cecal coccidiosis was light, as indicated by a mortality of 15.1 and 11.3 percent in the untreated pens of two experiments, protection was almost complete in corresponding pens of chicks receiving 0.5, 0.75, and 1 percent levels of sulfaguanidine. When infection was heavy, causing 94.6 percent mortality in the untreated pen, the mortality in the corresponding pens receiving 0.5 and 0.75 percent sulfaguanidine ranged from 20 to 54.1 percent. An 80 and 83.3 percent mortality in untreated pens corresponded to 2.7 and 3.6 percent mortality in pens receiving

1 percent sulfaguanidine. A relationship between the severity of the disease and the amount of the drug necessary to give complete protection from losses was thus indicated.

Chicks that had been inoculated and treated were found to be completely immune to a second inoculation without a second treatment. Inoculated chicks developed the disease in unison, while in natural outbreaks the disease developed in series in the chicks. A period of consecutive days' treatment as used successfully in inoculated birds was found not applicable in the control of natural outbreaks.

When chicks were treated for a continuous period of time beginning before or at the onset of a natural outbreak of cecal coccidiosis, symptoms and losses were checked, but susceptible chicks remained and went through the disease after termination of treatment. A schedule of intermittent sulfaguanidine feeding coordinated with the development of the natural outbreak appeared to give the greatest protection from losses in birds passing through a natural infection with cecal coccidiosis. The schedule used consisted of three 1-day feedings of 1 percent, or 1 lb. of sulfaguanidine in 100 pounds of mash, beginning with the first sign of the disease and allowing 4 days between treatments.

"In naturally developing cecal coccidiosis, treatment apparently must be short and repeated. The degree of success of the treatment will depend on the proper coordination of the sulfaguanidine feeding with the course of the disease."

**Seventh annual report of the Regional Poultry Research Laboratory, East Lansing, Michigan, July 1, 1945, to June 30, 1946 (U. S. Dept. Agr., Bur. Anim. Indus., [1946], pp. 11+).**—This report again (E. S. R., 94, p. 259) deals largely with studies on lymphomatosis. A table shows that the mortality to 300 days of age for 7 resistant lines amounted to 11.4 percent as compared with 24.9 percent for 7 susceptible lines. Additional information on natural transmission confirmed the results previously reported that breeding, the age of the chicken at the time of exposure, the degree of exposure to the causative agent, and the environmental conditions under which the birds are raised influence the incidence of lymphomatosis. In studies on transmission by inoculation, a high degree of success was attained in transmitting a condition that stimulates lymphomatosis when cellular material from lymphomatous birds is used as an inoculum. In certain cases of naturally occurring visceral lymphomatosis, a cell-free filtrate was prepared from tumorous organs which will produce lymphomatous tumors in susceptible recipients after an incubation period of 4 to 6 mo. which are indistinguishable from lesions of the naturally occurring disease by all criteria employed. Filtrates prepared from these tumors will produce similar tumors when passed to the next group of recipients, and the tentative conclusion is drawn that the filtrate contains an agent which has some of the properties of a virus.

Preliminary research suggested the possibility of differentiation in degrees of resistance in stock by the use of carcinogenic compounds. White Leghorn chickens known to be relatively resistant to lymphomatosis showed a much lower incidence of induced tumors among young chickens from inoculation of the carcinogenic agent than occurred among chicks from known susceptible lines.

Sulfamerazine given at the rate of one-half of 1 percent of the diet for a period of 300 days failed to reduce the incidence of lymphomatosis in a group of 37 females no less than that which occurred in a group of 46 birds not receiving the drug.

In comparative pathologic studies of neural lymphomatosis and symptomatically related diseases, cases of clinical paresis in 10-day-old and 6-week-old chickens were found at the Connecticut Storrs Station to be due to astrocytomas

in the mesencephalon and another case in a 6-month-old pullet to traumatic tendinitis. Two cases of paretic Newcastle disease were found associated with myelocytomatosis and neural lymphomatosis, respectively, with the latter case showing perivascular cuffs, characteristic of lymphomatosis, in the white matter and typical glia foci characteristic of Newcastle disease, in the gray matter of the spinal cord. The diagnosis of Newcastle disease was confined serologically.

Results of inoculations of chicks and eggs at the Indiana Station in a study of the transmission of visceral lymphomatosis are also reported.

**Newcastle disease in poultry**, F. R. BEAUDETTE. (N. J. Expt. Stas.). (*Cornell Vet.*, 36 (1946), No. 2, pp. 105-117).—This review deals with species affected, symptoms and autopsy findings, laboratory diagnosis, and control, especially as to the merits of a program of complete eradication by slaughter methods.

**Use of the rapid whole-blood test for pullorum disease**, H. BUNYEA, revised by W. J. HALL, A. D. MACDONALD, and R. R. HENLEY. (*U. S. Dept. Agr., Misc. Pub.* 349, rev. (1946), pp. 19, illus. 9).—This is a revision of the edition previously noted (*E. S. R.*, 81, p. 847).

**The efficacy of recently developed sulfonamides against fowl typhoid**, E. N. MOORE. (Del. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 307-311).—Using lots of from 3 to 10 chicks of various ages, five sulfonamides were tested to determine their value in protecting birds artificially inoculated with *Salmonella gallinarum*. Sulfamerazine and two sulfonamide compounds were found to be highly effective in reducing the mortality, which ranged from 0.0 to 16.7 percent except in one lot which received 0.2 percent of a sulfonamide and showed a mortality of 50 percent. Sulfathalidine and sulfasuxidine were less effective, and the mortality rate varied with them from 33.3 to 83.3 percent.

"Due to the variables introduced in this experiment and the small number of experimental birds used, this study merely serves to demonstrate the relative efficiency which might be expected from the five sulfa drugs used. Further research will be conducted to determine the true value of the more promising drugs under field conditions."

**A factor in delayed production of *Eimeria tenella* oocysts**, E. M. DICKINSON. (Oreg. State Col.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 391-392).—Observations on oocysts propagated after various periods indicated that the older a culture of *E. tenella* the more delayed is the production of oocysts and apparently also the formation of schizonts. Freshly propagated and sporulated oocysts produced from a delayed culture, however, promptly returned to a shorter cycle.

**Observation of swine erysipelas in turkeys (including the public health aspect and possible human cases)**, G. W. STILES. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 109 (1946), No. 832, pp. 65-69, illus. 2).—Following a rainstorm and snowstorm late in September, swine erysipelas developed in a flock of 2,500 tom turkeys near Colorado Springs, Colo. Later the disease spread to a flock of 5,000 younger toms and hens. Death loss in the flock was about 10 times greater in the toms than in the hens. *Erysipelothrix rhusiopathiae* organisms were recovered on culture from 8 dead turkeys, and identified bacteriologically from the blood, liver, spleen, kidneys, bone marrow, brain, and subcutaneous tissues of the head. Infected pigs purchased during the summer appeared to be the probable immediate source of infection.

**Fowl typhoid diagnosed in guinea fowl**, E. N. MOORE. (Del. Expt. Sta.). (*Poultry Sci.*, 25 (1946), No. 4, pp. 387-389).—Fowl typhoid was diagnosed in a flock of guineas on a farm where it previously had been found involving the chickens and turkeys. Attempts to diagnose the disease among ducks and geese on this farm failed. It was not possible to determine definitely the primary source of infection on the farm.

Symptoms of fowl typhoid infection among the guineas were of little diagnostic value, for the birds appeared normal until a day or two before death. Just prior to death the infected birds became pale, listless, and refused to eat. "Poultrymen attempting to eradicate fowl typhoid or pullorum disease from a farm should consider the possibility of the guinea fowl acting as a carrier of one or both diseases."

**Salmonella barcelly in quail**, H. E. RHODES. (Univ. Ill.). (*North Amer. Vet.*, 27 (1946), No. 7, p. 419).—This organism was isolated from a group of quail chicks with a reported mortality of 60 percent.

## AGRICULTURAL ENGINEERING

**Surface water supply of the United States, 1944 parts 1, 2, 8, and 12** (*U. S. Geol. Survey, Water-Supply Papers 1001 (1946), pp. 634+, illus. 1; 1002 (1946), pp. 552+, illus. 1; 1008 (1946), pp. 311+, illus. 1; 1012 (1946), pp. 261+, illus. 1*).—These papers record measurements of stream flow for the year ended September 30, 1944, No. 1001 covering the North Atlantic slope basins; No. 1002 the South Atlantic slope and eastern Gulf of Mexico basins; No. 1008 the western Gulf of Mexico basins; and No. 1012 the Pacific slope basins in Washington and upper Columbia River Basin.

**Water levels and artesian pressure in observation wells in the United States in 1943.**—Parts 3, North-Central States; 4, South-Central States, O. E. MEINZER, L. K. WENZEL, ET AL. (*U. S. Geol. Survey, Water-Supply Papers, 988 (1946), pp. 352+, illus. 10; 989 (1946), pp. 194+, illus. 13*).—These papers record water levels and artesian pressure in observation wells in the North Central and South Central States for the year 1943. For wells not previously reported complete records are given, including those for the years before 1943, while for wells whose previously records have been published this volume records only the current year.

**Ground water supply of Prospect Valley, Colorado**, W. E. CODE. (Coop. U. S. D. A.). (*Colorado Sta. Tech. Bul. 34 (1945), pp. 40, illus. 13*).—A report of the results of a study of water-table fluctuations in Prospect Valley, begun in 1933 in connection with a general observational program of water-table fluctuations in pumping districts of the South Platte Valley. Prospect Valley comprises about 12,500 irrigated acres and the water table now stands at from 25 to 100 ft. below the ground surface. Analysis of the accumulated data indicates an average surface water supply of 5,500 acre-ft. with a safe underground water yield of 9,860 acre-ft. With an indicated field duty of 1.8 acre-ft. per acre the present area irrigated should be reduced some 4,000 acres, for should water conditions prevail as in average years and the present area be maintained, economic exhaustion will occur in from 14 to 18 yr.

**The bonding action of clays.**—II, **Clays in dry molding sands**, R. E. GRIM and F. L. CUTHBERT (*Ill. Engin. Expt. Sta. Bul. 362 (1946), pp. 46, illus. 17; also Ill. State Geol. Survey Rpt. Invest. 110 (1946), pp. 36+, illus. 17*).—This is a continuation of a fundamental study of bonding clays in dry sands (E. S. R., 94, p. 117). The objective of this study was to provide information leading to a better understanding of the properties of molding sands and bonding clays and hence to the more economical production of better castings.

"Data are presented showing the relation of dry compression strength to amount of tempering water for varying amounts of each type of clay. . . . Sands bonded with halloysite or kaolinite clays are unique in that they develop greatly increased strength without much loss of water when rammed specimens are allowed to dry slowly. This so-called air-set strength is different from green

strength or dry strength and was not found in sands bonded with montmorillonite or illite clays.

"A theory of dry strength is presented based on the wedge-block concept of holding strains in place. Air-set strength develops because a certain amount of time (measured in minutes) is required for some of the tempering water to penetrate masses of halloysite or kaolinite clay and to become fixed so that a strong wedge-block is formed.

"Because of air-set strength and other properties of some clays, it is difficult or for some clays impossible to predict the strength of a partially dried mold from simple green or dry strength determinations."

**Nomograph for calculation of over-all heat transfer coefficients**, H. J. GABBER and W. LICHT, JR. (*Indus. and Engin. Chem.*, 38 (1946), No. 7, pp. 757-759, *illus. 1*).—The authors present a nomograph which has been developed to aid in the solving of equations dealing with the rate of heat transfer from one fluid to another separated by a solid wall. Values of heat transfer coefficients can be determined for walls of flat sheets, curved sides such as pipes, and spheres. Example problems to illustrate the alining technic of the charts are also given.

**The double-edged stationary potato cutting knife for saving labor, reducing the spread of ring-rot, and reducing equipment costs**, J. L. PASCHAL, G. H. LANE, and W. A. KREUTZER (*Colorado Sta. Bul.* 493 (1946), pp. 12, *illus. 10*).—A descriptive account for the construction of the machine with directions for its disinfection and use.

**Farm buildings**, J. C. WOOLEY (*New York and London: McGraw-Hill Book Co.*, 1946, 2. ed., pp. 354+, *illus. 199*).—A book designed to aid in the presentation of subject matter by instructors to students, but also of value to farm managers, appraisers, county agents, and farm operators. The division into chapters is made from the standpoint of a unit for study rather than for the subject matter contained, thus: (1) General, (2) livestock and poultry buildings, (3) air-conditioning farm buildings, (4) building materials, (5) structural design, (6) buildings for storage, (7) the farm home, and (8) drafting.

**Handbook on design of slatted floor barn hay-driers** (*Blacksburg: Va. Polytech. Inst.*, 1946, pp. 27+, *illus. 17*).—The handbook is assembled by R. E. McKnight, and provides information on the design of slatted floor barn hay driers for the use of personnel actively engaged in the design of these systems. The design data presented represent the results of hay drier research work at the Virginia Polytechnic Institute in cooperation with the Virginia Farm Electrification Council as well as practical experience gained in the field. The design problem is divided into the following major phases: (1) Introduction, (2) requirements of the building, (3) parts of the system and their functional use, (4) types of air distribution systems, (5) selecting equipment, (6) design of the air distribution system—two examples with solutions, and (7) appendix of formulas.

**Storing turnips in bins with forced ventilation: A progress report**, D. COMIN and W. JUNNILA (*Ohio Sta. Bimo. Bul.* 240 (1946), pp. 73-76, *illus. 1*).—The authors report the results of one exploratory test for aerating a large pile of turnips with a blower arrangement similar to that used for drying hay in the mow. There was no difficulty in preventing an undue rise in temperature within the pile of 2,300 bu. at any time, and though the average temperatures throughout the storage period were higher than the most desirable value of 32° F. the turnips with one exception were in fine condition for marketing. The roots in a spot 5 ft. in diameter and 2 ft. down from the top surface of the pile did not keep well for field containers were dumped at this point and the space between the roots filled up with earth and trash which interfered with the free circulation of air. On the basis of this exploratory experience the feasibility of storing root crops in

large piles is indicated. "Further detailed experiments should indicate the value of the method under many environmental conditions and with other vegetables."

## AGRICULTURAL ECONOMICS

**Current Farm Economics [June and August 1946]** (*Cur. Farm Econ. [Oklahoma Sta.]*, 19 (1946), Nos. 3, pp. 55-99+, *illus.* 2; 4, pp. 103-132+, *illus.* 3).—Included in both issues are the usual reviews of the agricultural situation and tables of prices and price indexes, and No. 3 also contains articles on Farm Real Estate Activity in Oklahoma, 1945, by R. T. Klemme, L. A. Parcher, and E. C. Ford (pp. 69-93), which supplements Bulletin 291 (E. S. R., 95, p. 117); and Farmers' Returns From Fattening Lambs on Winter Wheat Pasture, Tonkawa Area, 1944-45, by W. F. Lagrone (pp. 94-97) (both coop. U. S. D. A.), which indicates that under the price relationships that prevailed in 1944-45, feeding grain at the rate reported by farmers with the highest gains to supplement wheat pasture resulted in returns per acre of wheat grazed that were only moderately larger than returns realized from lambs allowed about the same acreage per head but receiving no supplemental grain feeding.

No. 4 also contains The Oklahoma Cattle Industry in 1946, by A. W. Jacob (pp. 115-121); Oklahoma Farm Mortgage Debt, 1945, by R. T. Klemme (pp. 122-125); and Returns From Wintering Yearling Cattle on Wheat Pasture, Texas County, 1944-45, by W. F. Lagrone (pp. 125-129), which indicates that substantially larger incomes were realized from wintering yearlings on wheat pasture than would have been realized from renting out this pasturage at the going rental rate. Best gains were made when the grazing period was extended 75 days or longer. When wheat pasture of average or better quality was available, best returns per acre were obtained by allowing 3 to 4 acres per yearling.

**The farmer in the modern world**, T. S. HARDING. (U. S. D. A.). (*Rural Sociol.*, 10 (1945), No. 1, pp. 3-9; *Span. abs.*, p. 3).—The economic position of the farmer has grown increasingly worse with the improvement of farm technology. For years he has received a very small percentage of the national income in comparison with his proportion of the total population. Effective demand has not been great enough to consume his products, and, consequently, he had received no increase in income. Food prices have not been raised because that would necessitate an increase in the wages of labor; to this industry will not agree. As a result, industrial workers are unable to buy all the foodstuffs they need. At the same time, farmers cannot sell everything they produce. Two ways of meeting the farm and industrial problem have been suggested. The first is direct; it deals with the basic ills, mass employment and chronic overproduction, but involves collective action of democratic government to attain beneficial social and economic objectives and is not in accordance with the traditions of the American people. Also, such a plan would require more government control and planning. The second course of action assumes that nothing can be done about the basic cause of the difficulty, and efforts are made to treat the effects of a very imperfect society. Thus, the problem is never solved because the core of the matter is never removed.

**Changes in farming in war and peace**, S. E. JOHNSON (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1946, F. M. 58, pp. 99+, *illus.* 36).—This report summarizes a study that was begun in the fall of 1944 with the objectives of analyzing the changes in farming during the interwar and war years, appraising the forces back of the large increases in production, and evaluating some of their peacetime implications. The author discusses the significance of wartime changes, the foundation for increased production, and peacetime implications of interwar and war-time changes.

**Historical perspectives for post-war agricultural forecasts: 1870-1940.** A. W. ZELOMEK and I. MARK (*Rural Sociol.*, 10 (1945), No. 1, pp. 48-70; *Span. abs.*, p. 48).—"In planning for the future the agricultural experts postulate a post-war boom in American agriculture. Their 'forecasts' and 'projections' of a buoyant future give insufficient explicit consideration to depressive factors which in the past cast their shadows over the agricultural scene. Hence it is desirable to reexamine the past trends to prepare realistically for the future. A survey of American agriculture from 1870 to the World War II imbues one with a healthy scepticism. Although agricultural fortunes have waxed and waned, the secular trend has exhibited, in the main, preponderatingly depressive features. What expansive and contracting factors have yielded this result? How have they operated in the two main periods—1870-1920; 1920-1940? Could the farmer extricate himself from the impact of mounting production costs and falling prices? Through what remedial programs has he tried to do so? An understanding of the basic factors and their operation is indispensable to any realistic consideration of future plans and prospects."

**Economies of scale of farming in the southern San Joaquin Valley, California.** J. K. LEE (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1946, pp. 185+, *illus.* 19).—This is a study of the effect of size of farm upon the efficiency of operation and upon the returns to individuals directly dependent upon agriculture for their livelihood.

It is concluded that "the large and medium-large farms have a slight advantage over the medium-size farms in output per unit of capital employed. But judging from past performance the medium-size summer-field-crop and dairy farms and the medium-large fruit farms have the advantage over other size groups studied in maximizing work opportunity, agricultural production, and the potential trade, or in maximizing income for the maximum number of people directly dependent upon agriculture for their livelihood."

**Postwar readjustments in Massachusetts agriculture.** I. D. ROZMAN (*Massachusetts Sta. Bul.* 430 (1946), pp. 35, *illus.* 19).—The author concludes that in the postwar period adjustments in Massachusetts agriculture will be needed both to correct previous maladjustments and to meet new developments and situations. His analysis of commercial farming units in Massachusetts indicates that more than half of them fail to meet the desirable requirements of income for farm families. The greatest need is for the reconstruction of substandard farming units into efficient, economic family farms capable of providing an adequate level of living under modern conditions. The best opportunity for such reconstruction is found in the rebuilding of land resources which are at the basis of farm operations. Large areas of undeveloped farm land of suitable quality are available both on farms and in adjacent rural areas. Recent experience with modern power machinery, especially bulldozers, power shovels, and bog harrows, indicates that there is a good possibility for land clearing and development through removal of stones and stone walls, clearing of trees and brush, and drainage of fields. The irregular distribution of the available land and the complicated pattern of land ownership present some difficulties in adding new tracts from undeveloped areas to existing farm units. Management of farm woodlands, which represent about 37 percent of the total area of Massachusetts farms, will have to be integrated with other farming operations to secure higher returns to the producers. The improvement in the condition and productivity of pasture and hay lands, the most important assets in Massachusetts agriculture, will reduce costs and improve the position of many Massachusetts farms. The position of Massachusetts agriculture in the postwar period will be determined by the success in reduction of costs through the adoption of the most efficient

methods, whether they are in the use of land resources, the employment of labor, the use of machinery, or the marketing efforts.

**Looking forward in Oklahoma agriculture, L. E. HAWKINS, P. NELSON, ET AL.** (Coop. U. S. D. A. et al.). (*Oklahoma Sta. Bul.* 299 (1946), pp. 92, illus. 9).—This is a summary, prepared by the farm press and State and Federal agencies, dealing with agricultural and industrial development, production opportunities, physical resources for agriculture, agricultural credit, marketing and distribution, land tenure, and rural life and community organization.

**Looking forward in Oklahoma agriculture.—A summary** (*Oklahoma Sta. Cir.* 123 (1946), pp. 14).—This is a summary of Bulletin 299, noted above.

**Agricultural adjustments to improve farming opportunities** (*South Carolina Sta. Rpt.* 1945, p. 10).—It is stated that if the 1946 suggestions made were adopted, the percentage of cropland idle in the State could be cut in half and the percentage of cropland which is double-cropped could be increased about one-third in comparison with 1945. Some shifts from corn to small grain in the drier areas would provide opportunity for more double cropping, increase the feed supply, and substantially reduce the costs of production. Compared with the prewar years, 1937–41, there were, on farms in this State in 1945, 11 percent more milk cows, producing 14 percent more milk; 39 percent more hens and pullets, laying 70 percent more eggs; 111 percent more broilers and 188 percent more turkeys produced; and 15 percent more cattle and calves. Still further increases are suggested for 1946 with reason to believe that under the cropping program proposed, feed supplies would be adequate for the purpose.

**The economic outlook in Sumter, South Carolina, J. M. STEPP and S. F. PHILLIPS, JR.** (*South Carolina Sta. Bul.* 365 (1946), pp. 29, illus. 7).—This survey indicates that the employment problem in Greater Sumter during the next few years will be one of adjustments between race and sex rather than an overall shortage or surplus of workers. In view of the prospective surplus of Negro workers, there are opportunities for businesses offering employment to Negroes. An ample supply of white as well as Negro workers during the next few years is indicated, so that a variety of industrial and business development is not only possible but necessary if Sumter is to avoid considerable unemployment or considerable loss of population through migration. The survey indicates that the residents of Greater Sumter plan to build more than twice the number of houses during these 2 postwar years than they built during 1939 and 1940, and that nearly two and one-half times as much money will be spent on house repairs as was spent immediately before the war. The automobile industry will provide additional jobs. Finally, the mercantile and service establishments would realize increased prosperity if the Negroes of Sumter and Sumter County were provided with more productive and higher-paid work. The same is true for the low-paid white workers, but they are not nearly so numerous as the low-paid Negroes.

The survey was based largely on returns from approximately 500 questionnaires from all economic groups and institutions in the city and its suburbs.

**Charting a route for agriculture in West Virginia, F. D. CORNELL, JR., ET AL.** (*West Virginia Sta. Spec. Cir.* 2 (1946), pp. 64).—This is a basic statement concerning the conservation and use of the agricultural resources of West Virginia, prepared by the Post-war Planning Committee appointed by the director of the station for the purpose. The successive chapters deal with the general situation, population, the land and its resources, production and production factors, land, settlement, tenure, and farm labor, agriculture-industry relations, and farm family and community living.

**Postwar employment opportunities in an agricultural community, A. D. EDWARDS and I. A. SPAULDING** (*South Carolina Sta. Cir.* 72 (1946), pp. 15, illus.

4).—From the sample of one-third of the households of the white population of the Hollywood community in Saluda County in 1944 and 1945 39 males were reported as absent from the community as a result of the war; of these, 33 were engaged in military service and 6 were employed at work outside the community. Opportunities were noted for purchasing and renting land after the war for about one-fourth of these men. The services most needed, as indicated by both owners and tenants, are those of a market for eggs and poultry and of a physician. Other needed services include those of an electrician, dentist, nurse, and teacher of an auto mechanics or machine repair course, shoe repair shop, and radio repair shop. Another opportunity is to be found in custom farming. The use of a tractor was hired more frequently by farm owners than by farm tenants, but among both tenure segments there was a demand for their use which was not met. Interest in postwar repair of dwellings gives promise of possible employment in carpentering and allied activities, although the need for the services of a carpenter in the community was rated low by both farm owners and tenants. The analysis of the community members' intentions to make purchases after the war indicated that they will furnish a market for household appliances more readily than for farm machinery and equipment. The installation of electricity in more homes after the war would, without doubt, increase the opportunity for the sale of such commodities.

**Land tenure in Arkansas.**—IV, **Further changes in labor used on cotton farms, 1939-44**, O. T. OSGOOD and J. W. WHITE. (*Arkansas Sta. Bul.* 459 (1945), pp. 31, illus. 6).—This fourth bulletin (E. S. R., 90, p. 115) is based on a follow-up survey of farms included in a previous study (E. S. R., 84, p. 113).

Declines in number of resident families and single wage hands per 10,000 acres of cropland from 1939 to 1944 in the various counties in which surveyed farms were located ranged from about 40 in Pulaski and Independence Counties to 132 in Chicot County. Percentage declines by counties were: Chicot 35 percent, Mississippi 25, Pulaski 14, Clark 36, Pope 41, and Independence 32. Accompanying the decline in number of families was a redistribution of families by tenure. In each of the delta counties, beginning about 1941, there was a considerable shift from wage families to share croppers and some shift to renters, particularly in Chicot County. Wage families, more than any other group, moved to nonfarm employment. In 1944 share croppers made up a major part of the labor force in all except the upland counties. Share renters were relatively most important in Pope and Independence Counties, but were represented by the largest numbers in Chicot County. Wage labor was relatively unimportant in the coastal-plain and upland counties, particularly in 1944. In the Delta Type Area, where cotton acreage worked by wage labor had been increasing during the 1932-38 period, the proportion worked by this type of labor began to decline about 1941, while that worked by share croppers increased correspondingly.

The total number of acres of cotton per 10,000 acres of cropland decreased in all counties except Mississippi, particularly during the latter part of the period when labor shortages were most acute. Corn acreage declined more than cotton. From 1939 to 1944 the number of tractors per 10,000 acres of cropland increased in the three delta counties from 15.2 to 29.3 in Chicot, 27.3 to 60 in Mississippi, and 21.4 to 37.2 in Pulaski. In 1944 there were five 4-row cultivators and four 4-row planters per 10,000 acres of cropland in the Delta Type Area. The number of work stock per 10,000 acres of cropland in the various counties ranged from 269 in Pope County to 395 in Chicot County.

On the basis of number of resident families in relation to cotton acreage, the amount of labor available per acre of cotton in the Delta Type Area in 1944 was only about 81 percent as high as in 1938. The number of resident families in re-

lation to cotton acreage and production on cotton farms will probably decline further when machinery, equipment, and labor are again freely available, with the acreage per cropper again declining. The proportion of share renters will decline further, while the proportion of wage laborers and combination wage laborers-croppers will increase. Present trends toward concentration of production in the delta and other areas best adapted to mechanized production are expected to continue, the rate depending largely on the degree to which economic forces are restricted by arbitrary controls.

**Land ownership trends in North Dakota, selected years, 1929-1944.** L. W. WALLIN and R. ENGELKING. (Coop. U. S. D. A.). (*North Dakota Sta. Bul.* 337 (1945), pp. 19, illus. 2).—Private land ownership in the nine selected counties decreased from 94.9 percent of the total land area in 1929 to 83.3 percent in 1941, then increased to 89.7 percent in 1944. Land owned by individuals amounted to 89.1 percent of the land area in 1929, 74.1 percent in 1941, and 86.7 percent in 1944. The peak of corporate ownership occurred about 1939. The acreage owned by corporations amounted to 5.8 percent in 1929, 9.2 percent in 1939, and 3 percent in 1944. Land ownership by commercial banks was highest in 1929, that of insurance companies in about 1939, the Federal land bank in about 1941, and that of other classes of corporations in 1934. The peak of county land ownership in the nine selected counties occurred about 1941, when the counties owned 6.7 percent of the land area, as compared with 0.5 percent in 1929 and 3.1 percent in 1944. The acreage of State school and endowment lands amounted to 3.8 percent of the land area in 1934, 4.8 percent in 1941, and 4.2 percent in 1944, and land owned by the Bank of North Dakota in these years 1.1, 3.4, and 1.2 percent. The acreage of Federal land ownership, including Indian land, for the State as a whole, decreased nearly 50 percent from 1929 to 1934, but was slightly higher in 1944 than in 1929. The percentage of public ownership for the whole State of North Dakota reached a low point in 1924 of 7.5 percent of the total land area. It increased to 21.1 percent by 1941, then decreased to 15.6 percent in 1944.

**Washington Farm Security Administration borrowers weigh the future: A comparison of their views with those of large-scale operators.** P. H. LANDIS (*Washington Sta. Bul.* 472 (1946), pp. 16).—Two samples were compared, one from 1,850 larger-than-average farms and the other, collected a year later, 450 Farm Security Administration borrowers who owned smaller-than-average farms.

The attitudes of the two samples toward problems of postwar planning were, for the most part, alike. On matters having to do with government activity in the field of national agricultural policy, public welfare, subsidized consumption, and medical care, the Farm Security group expressed more liberal attitudes. They also expressed more liberal views on the matters of tariff policy. On the matter of cooperatives, their views are more conservative, and they were also more negative toward the idea of part-time farming. The study of both groups indicated clearly that farmers from all economic levels are conscious of problems of health and medical care in their communities. Sentiment strongly favors some kind of cooperative approach to health insurance. Generally, farmers expect a depression within 10 yr. after the war. Most communities expect an increase in population, and more than a third expect a "back-to-the-land" movement that will affect their neighborhood. Generally, farmers are fairly optimistic about the ability of their neighborhood to offer employment to a substantial proportion of those who return to it from the war industries or from the armed forces. Considerable opinion favors government supervision and control of agriculture, and a substantial majority placed on

the National Government the responsibility for seeing that everyone has a job if private enterprise should fail to provide all with work.

**Farm tenancy in the United States, 1940-1945: A list of references,** A. M. HANNAY (*U. S. Dept. Agr., Libr. List 2, rev. (1946), pp. 84*).—This is a revised list of 546 references (*E. S. R., 87, p. 555*).

**Father and son farm agreements,** R. T. BURDICK (*Colorado Sta. Bul. 491 (1946), pp. 15*).—Three types of agreements between father and son are presented.

**Technique for classifying farm land for tax purposes,** W. P. WALKER (*Maryland Sta. Bul. 442 (1946), pp. 155-170+, illus. 2*).—Acreages in land assessment classes were compared with acreages actually in land-use classes for 472 farms in 6 counties of Maryland. Considerable difference existed between the acreage assessed and the acreage used as tillable and pasture land for individual farms, based upon land use on farms under the U. S. D. A. Soil Conservation Service program. There was an average misplacement of 12 percent assessment due to failure to keep land assessment classes up to date. For nearly half of the farms the erroneous assessments amounted to 10 percent or more and averaged 22 percent. When the programs on such farms are completed, there will be a much greater difference between the assessment class acreages and land-use acreages. For the group of farms studied there were, on the average, about half as many assessment rates on arable land as there were distinct land capability grades. Most farms in Maryland have arable land of several distinct grades, and this fact justifies a wider range in assessment rates against arable land for individual farms than is commonly practiced in the State. Furthermore, greater emphasis could be placed upon land capability as one important factor in determining basic assessment rates, with additions or subtractions from such rates depending upon the use made of land or the type of woodland.

**An economic study of local government in fifty Vermont towns,** J. J. DALTON and S. W. WILLIAMS (*Vermont Sta. Bul. 532 (1946), pp. 48, illus. 10*).—This study of economic aspects of local government in Vermont was based upon detailed financial and related information covering the operations of 50 towns during the town fiscal year ending January 31, 1933.

State aid for roads and schools is an important item of town income, and town finances are considerably affected by the regulations that govern its apportionment. State aid for schools was available only to towns with school-tax rates of \$0.75 or more per \$100 of assessed valuation and poll taxes, and the amount these towns received varied directly with their school-tax rates. The rate of assessment varied from town to town and also within individual towns, the variation in the latter case reflecting chiefly a tendency to overappraise properties of low value in relation to those of high value. However, in any given price range, farms were assessed at a higher percentage of sale price than village properties. Nearly two-thirds of the town revenue was derived from taxes, and most of the remainder from State aid for roads and schools. Expenditures for roads and schools, which were approximately equal, together accounted for four-fifths of the total expense. Salaries and wages were major items in the cost of both roads and schools.

Differences in population per town apparently were not responsible for any large part of this spread in tax rates. The increase in population per town that was associated with a rise in the population per square mile, with no change in area, was accompanied by a decrease in costs, particularly highway expense. Taxes declined less than costs, however, because the amount of State aid decreased as the population per square mile increased. Tax rates were more

closely correlated with the amount of taxable wealth. Governmental costs, although fully as high in relation to the number of people, were much lower in relation to the sale value of the taxable real estate in the towns with comparatively large amounts of taxable wealth per person than in those with small amounts. Costs and taxes were lower in relation to property values in the towns that were best suited to farming than in the others, but they were not lower in relation to population.

Three measures of the tax burden on farms were used. Farm taxes were low in the towns in which the land was best suited to agriculture, in those having the smallest share of their road mileage in town roads, and in those in which the tax levy per person was comparatively small. They were slightly below average in the towns having the most people per mile of road and in those that operated elementary schools only. Farm taxes were low in relation to property values, though not in relation to the apparent income-producing capacity of the farms, in the towns with the most people per square mile and in those with the largest amounts of taxable wealth.

**Income and expenses in growing and marketing Irish potatoes, Cumberland Plateau, 1943-1944.** F. N. MASTERS and C. C. MANTLE (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 204* (1946), pp. 80+, illus. 11).—Potato yields of 111 bu. per acre returned farm operators about \$86 per acre above expenses compared with \$42 per acre above expenses reported by operators with potato yields from 56 to 110 bu. per acre, and a loss of \$33 per acre for operators reporting yields up to 55 bu. Certified potato seed averaged over 20 bu. per acre more than select or other potato seed. Those growers who used mechanical spraying machines found that the total expense of each application was about \$2.50 per acre. Potatoes harvested before August 1 had highest yields, highest prices, and highest returns per acre over expenses, in 1944. Price per bushel averaged highest for those potatoes marketed before August 1, and lowest for those marketed during the month of August. Highest price per bushel was obtained by growers reporting yields of over 100 bu. per acre and having better than average returns per acre over expenses. The average estimated residual value of commercial fertilizer per acre in 1944 was \$7.28, \$6.45, and \$6.38 in Cumberland, Morgan, and Sequatchie Counties, respectively. Farm operators with yields of 200 bu. of potatoes in 1943 reported incomes of \$250 per acre. Approximately 128, 96, and 81 man-hr. per acre of potatoes were required by the average high-, medium-, and low-yielding operators, respectively. Failures of producers to select good seed, carelessness in handling and packing, and strong marketing competition from other areas are some of the reasons for the precarious situation of many potato growers.

**New Mexico vegetable production in relation to freight rates.** P. W. COCKERILL (*New Mexico Bul. 329* (1946), pp. 17, illus. 1).—This report reviews the history of vegetable shipping from New Mexico and considers the factors which will effect future production, with special reference to transportation costs. It is designed not to cover the subject completely, but, rather, to emphasize the effect of inequities in freight rates.

It is noted that "the present period of high prices may be the last time for a considerable number of years in which New Mexico will have as favorable an opportunity to become established in vegetable production. To become established in this industry three things must be accomplished: (1) Production efficiency and skills must be developed; (2) a reputation for high quality products must be built up on the central markets; and (3) a large volume of production of each vegetable must be maintained every year in order to obtain the needed equalization of rates. If these three things are accomplished during

the present favorable period the industry will be in much better condition to weather a period of lower prices.

**Readjustments in processing and marketing citrus fruits**, H. L. COOK ET AL. (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, pp. 190+*, *illus. over 25*).—This publication is one of several dealing with postwar readjustments in the marketing of agricultural products, prepared by or at the suggestion of the Working Group on Conversion of Marketing Facilities and Methods of the Interbureau Committee on Postwar Programs. The purpose of the study is to examine trends in production and prices and to evaluate outlets which may keep prices in line with costs. The inquiry into outlets includes an estimate of opportunities for increasing exports of citrus and citrus products, for improving the competitive position of fresh citrus marketed domestically by economies in marketing, and possibilities of expanding the processing outlet. Consideration of processing includes techniques and costs of production, and the competition faced by citrus products and byproducts.

**More eggs produced per man hour**, I. R. BIERLY and L. M. HURD. ([N. Y.] Cornell Expt. Sta.) (*Farm Res. [New York State and Cornell Stas.], 12 (1946), No. 3, p. 16, illus. 1*).—Two years ago a study comprising eight farms was initiated to determine why some farmers can care for more hens in a given amount of time than can others. On these farms, the time to care for 1,000 hens varied from 21 min. to 2 hr. a day; the distance traveled, from  $\frac{1}{8}$  mile to  $1\frac{1}{2}$  miles a day. Studies were made of the floor plans of the poultry houses, the kind of equipment used, the location of the equipment in the pens, and the way the work was organized.

It was found that one poultryman cut in half the manpower needed to care for his flock by taking out partitions so that he now has one large pen where formerly there were eight smaller ones. On some of the farms two or three jobs were accomplished during each trip with only two to four trips to each pen daily. Other farmers did one job at a time and made eight or nine trips, and the number varied from three to seven jobs on the farms studied. Automatic waterers eliminated one daily task on some farms. Some farmers supplied dry mash only once in 2 days, while some fed wet mash and pellets in addition to dry mash and grain. Cutting down on the time spent on the present flock through improved work methods may make it possible to care for more hens—and to produce more eggs per man hour.

**Milk production costs in N. E. Mississippi**, W. J. EDENS (*Miss. Farm Res. [Mississippi Sta.], 9 (1946), No. 3, p. 8*).—This progress report on the study started in 1944 includes data for that year as to total costs of production, profits, and labor returns from milk production; average annual production and cost of keeping a cow; and other data collected on 40 farms in north-eastern Mississippi.

**Harvesting the hay crop**, A. P. BRODELL, T. O. ENGBRETSON, and C. G. CARPENTER (*U. S. Dept. Agr., Bur. Agr. Econ., 1946, F. M. 57, pp. 22+*, *illus. 6*).—This report contains statistical information concerning haying methods and practices and is based largely on information obtained in 1945 by means of mailed questionnaires from about 20,000 crop correspondents.

**Tobacco crop insurance in Tennessee**, B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 202 (1946), pp. 29+*, *illus. 9*).—Tobacco trial crop insurance, offered tobacco growers in Maury and Greene Counties on the 1945 crop and carried on 1,376 farms, represented an average participation in the program by about 20 percent of the growers and 18 percent of the total tobacco acreage allotment. About 12 percent of all insured farmers had tobacco crop losses in 1945; on an acreage basis about 20 percent of the insured acreage

was indemnified in Greene County, and 53 percent in Maury County. Idemnities paid, as a percentage of premiums collected, averaged 31 percent in Greene and Maury Counties in 1945.

The average county yield in pounds of tobacco per acre varied from 975 to 1,530 in 1944. The average annual loss on 465 better tobacco farms in Tennessee, from 1935 to 1941, was 45 lb. per acre, and the percentage that annual loss is of average yield was 3.7.

It is concluded that farmers growing tobacco are likely to experience either a major or minor loss in 1 of 7 yr. The loss from unavoidable production hazards for the period 1934 to 1943 in Tennessee is estimated at 250 lb. per acre. Based upon the first 5 days of auction sales for the entire Burley area (43.4 ct. per pound), the insurance premium rate in Greene County in 1945 averaged \$23 and that in Maury County \$22 13 per acre. The premium rates in pounds per acre were 53 and 51, respectively.

The operations and management of 13 farmers' cooperatives in north Georgia, 1944, N. M. PENNY (*Georgia Sta. Bul.* 246 (1946), pp. 20, illus. 1).—This study brought out that the associations analyzed have volumes of business that are too low for most efficient operation, especially in marketing farm products, which is indicative of lack of proper support by the farmers of the area. A standardized method of bookkeeping and accounting and a fiscal year with the same ending should be adopted. The terminology and forms for financial statements for cooperatives approved by the American Institute of Cooperation are recommended. The organizations should own their own land, buildings, and facilities or have long-term leases in order to be divorced from the hazards of changes in use made of the facilities. The cooperatives should have greater leadership from the ranks of their members. A long-time objective of the educational program should be to become entirely independent of public agencies for leadership and to use those agencies only for advice, information, and consultation.

Relationships between cooperative organizations serving farmers in five Ohio counties, G. F. HENNING and L. B. MANN. (*Coop. U. S. D. A.*). (*Ohio Sta. Bul.* 660 (1946), pp. 43, illus. 2).—Conclusions reached from this study were as follows:

It should not be difficult to become a member of a cooperative, and nonmembers should be encouraged to join as a fundamental principle. The members are in favor of having some device whereby the nonmember who trades with the cooperative is made a member, as by applying the patronage dividends toward the share of stock, a membership fee, or whatever else may be the requirement. When an association uses capital stock, it should be of small units, probably \$5, \$10, or \$20 per share. If the organization needs more capital per member than what one share would furnish the association, it can require 2, 3, 4, 5, or more shares. The cooperative at certain periods should have a membership campaign and invite the young farmers, tenants, and others who have moved into the area to become members.

There was no general policy followed by the cooperatives considered in this study on eliminating the inactive members or the deadwood of the organizations. The time of returning the inactive member's investment in the cooperative (whether it be stock, retained savings, or reserves) should be left to the cooperatives, except that in the case of the death of a member the cooperative should return his equity or investment within 1 yr.

Savings should be distributed according to the broad principles of cooperation and sound business procedure as to patronage, with a distribution to all patrons contributing the volume of business rather than on a basis of investment. No dividend should be declared on retained capital, as this will help to keep down

the number of inactive members. Savings can be distributed by patronage in cash, issued stock, or accumulated toward the purchase of a share or certificate. Some cooperatives merely made allocations to their patrons on their books. If the cooperative is out of debt and has no desire to expand, then a large portion of the savings should be paid out in cash and only enough retained to place the cooperative in a strong financial position. A revolving plan is followed by some Ohio cooperatives; this system maintains the cooperative on a basis financed by the members who use it and reduces the interest of the inactive members in the cooperative.

**Sales and consumer acceptance of certain dehydrated vegetables in Grand Rapids, Michigan.** J. C. MOORE (*U. S. Dept. Agr., Farm Credit Admin., Misc. Rpt. 99 (1946), pp. 32+, illus. 1*).—This report is concerned with the distribution of dehydrated vegetables through regular trade channels and the consumer acceptance of these items in Grand Rapids, Mich., under practical marketing conditions from March 6 to September 30, 1945. The products included were diced beets, carrots, sweetpotatoes, white potatoes, onion flakes, and julienne white potatoes. Approximately 18,000 cans of each of the 6 products were packaged in tin containers designed to hold 4 servings each. As a result of the initial efforts, sales averaged over 1,600 cans the first week. Sales gradually declined, however, for the next 8 weeks and then increased until a weekly volume of over 1,000 cans was reached. It is concluded that "dehydrators who contemplate selling their products through retail channels of distribution may expect to encounter considerable buying inertia on the part of retailers and consumers which can be overcome only by extensive and expensive advertising and promotion of acceptable products."

**Housewives prefer prepackaged produce.** C. W. HAUCK (*Ohio Sta. Bimo. Bul. 240 (1946), pp. 76-88, illus. 8*).—Because of the trend toward prepackaging of foods in consumer units, the station has been exploring possibilities in this direction since 1945 in cooperation with one of the large corporate chain grocery companies operating in the State. The retail stores and warehouse of the company in Columbus have been serving as a laboratory for this purpose; in these supermarkets the produce departments have been equipped with open-top self-service type refrigerated sales and display cases, and these are kept stocked with consumer units of fresh fruits and vegetables, precooled, trimmed, and prepared in the central warehouse, packaged in paperboard trays or "boats" overwrapped in transparent sheet Cellophane. Most of the extra costs have been met by savings at various points, by extension of the "shelf life" of these perishables, and by increases in sales volume, without advancing the retail price of the packaged items over that of identical goods sold from bulk. Sources of savings include the elimination or reduction of waste, reduction of weight or bulk, and less labor because of self-service.

This new method of offering fresh fruits and vegetables has met very encouraging consumer acceptance, especially among those with 2, 3, or 4 persons in the family who furnished most of the patronage. In these groups 18 to 26 percent of the patrons wanted some items packaged in smaller consumer units.

The author concludes that if prepackaging of fresh fruits and vegetables is to be permanently successful it must be accompanied by exacting care at all points in the grading and packaging operations, constant effort to maintain a high standard of quality and freshness, rapid turnover, and a sincere readiness to replace any unsatisfactory purchase with good merchandise or to refund the purchase price.

**Index numbers of production, prices, and income.** J. I. FALCONER (*Ohio Sta. Bimo. Buls. 240 (1946), p. 92; 241 (1946), p. 114*).—In Bulletin 240 the table

of index numbers is brought up through February and in Bulletin 241 through April 1946.

Statistics pertaining to the 1946 demand situation for canning peaches, H. R. WELLMAN and B. H. SCHULTE (*California Sta. Mimog. Rpt. 87* (1946), pp. [21])—There are 24 tables, but no discussion.

## RURAL SOCIOLOGY

**Review of current research in rural sociology**, R. M. WILLIAMS, JR. (Cornell Univ.). (*Rural Sociol.*, 11 (1946), No. 2, pp. 103-114; *Span. abs.*, p. 103).—This report outlines six criteria for appraising rural sociological research: (1) Methodology; (2) scientific importance; (3) social importance; (4) effectiveness of presentation; (5) economy of investigation; (6) adherence to the norms of "good scholarship." Discussion is limited to the first four criteria.

[Dwight Sanderson Memorial Number] (*Rural Sociol.*, 11 (1946), No. 1, pp. 90, *illus.* 1).—In this issue the following papers are included: Dwight Sanderson—Rural Social Builder, by W. A. Anderson (pp. 7-14) (Cornell Univ.); Dwight Sanderson—Social Scientist, by C. C. Taylor (pp. 14-23) (U. S. D. A.); Group Classification—Dwight Sanderson's Contribution, by H. W. Beers and J. H. Kolb (pp. 23-35) (Ky. and Wis. Univs.); The Family, by R. G. Foster (pp. 35-42); and The Concept of the Community, by D. Ensminger and R. A. Polson (pp. 43-51) (U. S. D. A. and Cornell Univ.).

**Some effects of the war on rural life in Missouri, 1939-1945**, G. SCHULTZ (*Missouri Sta. Res. Bul.* 401 (1946), pp. 36, *illus.* 5).—The author finds that the response of the rural population to the requirements of national defense was wholly satisfying and in complete accord with the traditional patriotism of the farm people of the United States. The alacrity and success with which farmers shifted and directed their efforts to meet the demands of wartime production amply demonstrated their adaptability and the flexibility of American rural economic and social organization. The exceptionally heavy losses of population through entrance into the armed forces and migration to war industries stands as one of the most significant effects of the war upon rural Missouri. A significant effect of the war has been the marked increase in rural community contacts with the outside world, both at home and abroad. The abundant news, by press and radio, covering significant war events throughout the world—events that involved local boys—kept rural people news conscious. Furthermore, wartime government agencies settled their controls upon the rural communities and regulated daily affairs in such a way that rural people could scarcely fail to be impressed by their close relation to the national whole. Another outstanding effect of the war was the increased prosperity it brought to rural Missouri. Debts were paid, inventories were improved, and, with opportunities for spending curtailed, some money accumulated. The scarcity of consumption goods prevented much improvement in mode of living. Indeed, housing, farm buildings, conveniences, and much equipment tended to deteriorate for lack of replacements. On the whole, rural life was not seriously disrupted by the war. There were fewer people on farms and they worked harder. Rural organizations did not appear to suffer. There seems to have been some increase in local cooperative effort, chiefly by way of mutual aid. No social or cultural upheaval occurred. Rural Missouri "took the war in stride." Perhaps the most profound effects have been registered in terms of changes in attitudes, outlook, and habits of thinking.

**The challenge of tomorrow's rural life**, W. A. ANDERSON. (Cornell Univ.). (*Rural Sociol.*, 11 (1946), No. 2, pp. 120-127; *Span. abs.*, p. 120).—Extraordinary population changes presage the urbanization of rural areas, the elimination of

most distinctions between urban and rural, and the building of the mechanized rural community. This has come about as a result of the revolution in transportation, especially the automobile and paved road; the changes in communications; the commercialization and mechanization of farming; the mechanization of the rural home; and changes in rural social institutions, especially in the school and in government.

**Rural life promises much for the future**, W. A. ANDERSON. ([N. Y.] Cornell Expt. Sta.). (*Farm Res. [New York State and Cornell Stas.]*, 12 (1946), No. 3, pp. 4-5).—A discussion similar to the above from which the author concludes that a major problem of tomorrow's rural life is the achievement of a constructive integration of urban and rural viewpoints.

**An Iowa locality, 1918-1946**, B. L. MELVIN (*Rural Sociol.*, 11 (1946), No. 2, pp. 115-119; *Span. abs.*, p. 115).—In 1918 Savannah, a small hamlet in southeast Iowa, was the partial service center of the locality consisting of two county school districts. The community activities gravitated around the store, the church, the community house, and two rural schools. In mechanization the automobile was displacing the horse and buggy, but now farming is done with tractors, two- and three-bottom plows, combines, corn huskers, etc. Activities have shifted to the county seat, which is connected with Savannah by a gravel road and an electric line. The county agricultural agent, the home demonstration agent, the director of rural electrification, the representative of the Agricultural Adjustment Administration, and a soil technologist serve agriculture from the county seat, and trained veterinarian looks after the hogs, sheep, and cattle from the same center, but the people are not served therefrom in the fields of education, health, or religion. It is concluded that the State college and the Federal Government are doing an excellent job of caring for agriculture but not for the farmer and his family.

**Differential fertility in Louisiana**, J. A. BEEGLE and T. L. SMITH (*Louisiana Sta. Bul.* 403 (1946), pp. 44, illus. 21).—According to this study, largely an analysis of reproduction rates in 1940 based on the sixteenth U. S. Census, the rate of reproduction in Louisiana is still considerably above that necessary to replenish the population, but the relative importance of the basic stocks in the population is changing very rapidly. In proportion to population, the farm people of the State are producing more than two children for every one borne by the city people. "The State faces no greater problems than those of seeing that opportunities for healthful living, education, and the costs of rearing the oncoming generation are more equitably distributed among all its people." Contrary to popular belief, Negroes in Louisiana do not have a birth rate far above that of the white population. Farm Negroes are reproducing more rapidly than the whites who live on farms, but, on the other hand, urban Negroes are less prolific than urban whites. The population of French-Catholic south Louisiana is multiplying far more rapidly than that of Anglo-Saxon, Protestant north Louisiana. In common with the other Southern States, Louisiana is contributing a disproportionately large share of the Nation's future population. In comparison with most of the other States the rates of reproduction of Louisiana farm and rural-nonfarm population are very high; however, the birth rate of urban people in the State compares very closely with urban birth rates elsewhere in the Nation. Nevertheless, for at least 60 yr. Louisiana's rate of reproduction has been falling steadily.

**Rural and urban residence of the Negro in the United States**, S. C. MAYO. (N. C. Stat. Col.). (*Rural Sociol.*, 10 (1945), No. 1, pp. 10-16, illus. 1; *Span. abs.*, p. 10).—The Negro in America has for long been thought of as a typical rural dwellers hut, as measured by residence, on a proportionate basis he is

more urbanized than the white population. In North Carolina a larger proportion of the total Negro than the white population has been in urban centers for the past 120 yr. Also in all six of the major regions of the United States in 1940 a greater proportion of the Negro population was in urban centers, and this appears to be the continuation of a long-time trend. By comparing the proportion of the various total population classes in urban centers in 1920 and 1940 it is revealed that the Negro is becoming urbanized at a much faster rate than other racial and nationality groups in the United States.

**Kansas rural institutions.**—II, A pioneer in rural electrification, F. D. FARRELL (*Kansas Sta. Cir.* 236 (1946), pp. 23, illus. 7).—This is a discussion of an instance in which members of a small rural community have had throughout a quarter century an efficient and constantly improving rural electrification service through the operations of a farmers' cooperative association. The operations of this association, located at Berwick in the northeastern corner of Nemaha County, Kans., are described.

**Prepayment medical care in Nevada County, Arkansas,** T. L. VAUGHAN and H. PRYOR. (U. S. D. A.). (*Rural Sociol.*, 11 (1946), No. 2, pp. 137-147, illus. 1; Span. abs., pp. 137-138).—Farmers in this country organized their own cooperative health association in 1942 in an effort to provide themselves with essential medical care at a price which they could afford to pay. The program was one of seven sponsored and partly financed by the U. S. Department of Agriculture to determine feasible means of extending medical care in rural areas. Herein is a report on operations of the Nevada association during the 1942-43 and 1943-44 fiscal years. Prepayment of membership fees coupled with grants-in-aid went far in eliminating the economic barrier to medical services, but all groups did not take full advantage of services. Strong and weak points of the health service are summarized, with the conclusion that the Nevada plan is a step toward, but not a complete answer for, adequate medical care for rural people.

**The Wheeler County, Texas, Rural Health Services Association,** M. T. MATTHEWS. (U. S. D. A.). (*Rural Sociol.*, 11 (1946), No. 2, pp. 128-137; Span. abs., p. 128).—This study of this project indicated that prepayment medicine was not new to Wheeler County people. Local attitudes regarding Federal participation in health programs grew out of general and local crises which resulted in adjustments of older ideologies relating to such aspects of health care as minimum service standards and personal or group responsibilities. Unusual conditions surrounding program operation resulted in some decline of membership, but high program approval and morale were indicated by several indexes. Numerous improvements were suggested, many of which related to increased service coverage at somewhat lower costs with better access to the metropolitan type of clinical facilities.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Workers in subjects pertaining to agriculture in land-grant colleges and experiment stations, 1945-46,** B. T. RICHARDSON (*U. S. Dept. Agr., Misc. Pub.* 603 (1946), pp. 164+).—This is the usual annual list (E. S. R., 93, p. 383) of workers in agriculture and home economics in the land-grant colleges and experiment stations, the personnel of the Office of Experiment Stations, and the officers and standing and special committees of the Association of Land-Grant Colleges and Universities.

**Rural-urban differences in the educational status of Louisiana's white population,** T. L. SMITH and L. KEMP (*La. Rural Econ. [La. State Univ.]*, 8 (1946), No. 2, pp. 4-6, illus. 2).—In the United States farmers receive much

less formal schooling than the people who live in towns and cities. This unfavorable differential is greatest in the South, and the situation is particularly acute in Louisiana where adult white people living on farms have had only two-thirds as much formal schooling as their fellows who live in incorporated towns and cities.

**Rural education and welfare in the Middle East,** H. B. ALLEN (*London: Govt., 1946, pp. 24+, illus. 1*).—This is a report by the Director of Education of the Near East Foundation to the Director General of the Middle East Supply Centre. It deals with the rural situation in the Middle East and the role of education in meeting the problems confronted.

### FOODS—HUMAN NUTRITION

**The new flour: Baking qualities,** M. T. SWICKARD. (U. S. D. A.). (*Jour. Home Econ., 38 (1946), No. 6, pp. 353-354*).—All-purpose and cake flours available at the time of the War Food order were used for controls in determining the baking qualities of 80 percent extraction flour. Those used in the tests included flours milled from hard and soft wheat. The 80 percent extraction flours, except one soft wheat, weighed slightly less per unit of volume than did the control flours, indicating that the batters and doughs would be softer and adjustments in measurements necessary.

Biscuit doughs were soft and difficult to handle when the 80 percent extraction flours were used measure for measure, although three of the four test doughs so made gave excellent biscuits. The best biscuits made with the hard wheat were produced by using the same measure of flour and liquid as in standard recipes. Griddle cakes, pastry, and cakes were found to be sticky in texture when the soft wheat was used in the same proportions in standard recipes; better results were obtained when the hard wheat flour was used in standard proportions and the liquid was not readjusted. In general, the results of the test bakings showed that the products made from the new flour were more tender and moist than those made from the control flours.

**To enrich or not to enrich: A symposium,** E. V. MCCOLLUM, R. M. WILDER, A. F. MORGAN, and H. S. MITCHELL. (Univ. Calif. et al.). (*Jour. Home Econ., 37 (1945), No. 7, pp. 397-402*).—This symposium deals with mandatory enrichment of white flour and bread.

**Enrichment of corn meal and grits** (*South Carolina Sta. Rpt. 1945, pp. 72-75, illus. 2*).—Experimental premixes of desired composition were prepared and tested, and small machines were designed (diagrammatical drawings given) for feeding the premix into the meal and grits as they were ground. These feeders are being used in 130 corn mills in South Carolina to bring corn products up to the nutritional standards recommended by the Nutrition Board of the National Research Council.

**Effect of method of combining the ingredients upon the quality of the finished cake,** G. L. TINKLIN and G. E. VAIL. (Kans. Expt. Sta.). (*Cereal Chem., 23 (1946), No. 2, pp. 155-165*).—Investigations made on the effect of different methods of combining the ingredients of a simple cake upon the characteristics of the batters and the baked product are reported. The consistency and the specific gravity of cake batters prepared by six general methods of mixing were determined and relative shortness, compressibility, and eating quality of the finished cakes were evaluated approximately 20 hr. after baking.

Batters with a wide range in consistencies were found when the ingredients were combined by varying methods. Each method tended to give a characteristic batter, ranging from the thinnest, which took 0.2 min. to flow through a 5.0 cm.

stemmed funnel, to 52.8 min. for the thickest. Consistency and specific gravity were found to be closely related, indicating that the amount of air incorporated in the batter may be an important factor in determining its consistency. Specific gravity ranged from 0.7368 to 1.0351 for the individual cakes and from 0.7509 to 1.0298 for the different methods employed. Cakes of low specific gravity tended to give cakes of good volume which were evaluated as tender and compressible.

Cakes mixed for a short period had a coarse, loose, porous texture, but those methods requiring the most time did not necessarily give the best results. Significant correlations were found between shortness and compressibility, with specific gravity, and with palatability.

**Does nitrogen affect pea quality?** C. B. SAYRE. (N. Y. State Expt. Sta.). (*Food Packer* 27 (1946), No. 5, pp. 68, 70-71, *illus.* 2).—Essentially noted from another source (E. S. R., 95, p. 330).

**Shelf life of fresh fruits and vegetables can be lengthened,** C. M. HAUCK (*Ohio Sta. Bmo. Bul.* 241 (1946), pp. 100-103, *illus.* 1).—The factors affecting shelf life are discussed, and tests of the advantages of prepackaging with cellophane and refrigeration are reported with 14 root crops, green and leafy vegetables, and citrus and deciduous fruits. Packing and refrigeration together produced results much better than either alone, although not uniformly effective on all commodities tested. The importance of initial handling is also emphasized.

**Storage of pork products** (*South Carolina Sta. Rpt.* 1945, pp. 67-68).—Experimental data are presented on the effect of temperature and storage methods on sausage, cured hams, and bacon. Uniform methods were used in cutting, curing, and smoking the hams and bacons. After smoking, the samples were stored at room temperature and at 36° F. in refined cottonseed oil, raw cottonseed oil, and in cotton sacks. Bacon samples stored without the use of oil were given the same score after 40 weeks of storage whether stored at room temperature or at 36°, but samples stored in raw or refined oil at 36° were given a perfect score at the end of 48 weeks whereas those stored at room temperature did not grade above moderately desirable at any test date. Up to 32 weeks of storage, hams kept without oil at room temperature or at 36° were found to be desirable in quality. Those kept in oil at room temperature showed a gradual decline in quality after the first 8 weeks and were classified as only slightly desirable after 48 weeks; at 36° there was some decline in quality after 16 weeks of storage. Raw oil was the more desirable storage medium at 36°, while refined oil gave best results at room temperature.

Sausage stored in open containers and covered with lard, refined oil, or raw oil deteriorated in quality after the first test period of storage at 8 weeks. Sausage which was processed and sealed in tin or glass showed a slight decline in quality but was graded moderately desirable at the end of the test. Frozen sausage lost quality and flavor as the storage period progressed.

**Dehydration of vegetables and fruits** (*Florida Sta. Rpt.* 1945, pp. 81-82).—A. L. Stahl and F. S. Jamison, report that cabbage, beans, collards, broccoli, and carrots from eight widely separated locations in Florida and additional samples from plots of three fertilizer levels at these locations were dehydrated under various conditions. Fertilizer level had no apparent effect on the dehydrated vegetables, but the best products were obtained from those locations, notably those with muck soils, producing good succulent growth. From one-third to one-half of the original ascorbic acid was lost even in the best controlled dehydration of the vegetables, and another one-fifth to one-third was lost in cooking after dehydration. Ascorbic acid content was highest in the products stored under refrigeration in the dark in moisture—and air-proof containers. New dehydrated products included dehydrated celery and spinach powders, prepared

from vegetables and fruit wastes. A satisfactory boiled dehydrated peanut was prepared.

**Nutrition Foundation investigation on nutritive value, oxidative enzymes, and other factors in certain commercially dehydrated vegetables,** L. A. MAYNARD, W. L. NELSON, W. A. GORTNER, J. M. NELSON, C. R. DAWSON, and M. F. MALLETT (*Ithaca, N. Y.: Cornell Univ., School Nutr.: New York: Columbia Univ., 1946, pp. 16+*).—This mimeographed report deals with the investigation of the causes of the rapid deterioration of the dehydrated products purchased by the armed forces. Commercially dehydrated cabbage, potatoes, and sweetpotatoes were placed in controlled storage for 1 yr. under experimental conditions of temperature and moisture. Control, blanched, and dehydrated samples were assayed for vitamin, oxidative enzymes, "available" iron, total copper, and moisture content.

The dehydrated cabbage and potato samples showed extensive and rapid storage deterioration as evidenced by loss of vitamin C, discoloration, and off-odors under storage conditions of 70° to 80° F. and 7 percent moisture. Lower storage temperatures kept products more stable. Correlation between this deterioration and oxidative enzyme, copper, and iron contents were not evident. All the vitamins assayed except ascorbic acid were found to be fairly stable during the controlled storage. Sulfite blanching reduced the ascorbic acid losses in the cabbage after storage periods, but thiamine was destroyed.

"The data refute the view that the storage deterioration of commercially dehydrated cabbage and potatoes may be due to the action of oxidative enzymes whose presence might arise from inadequate blanching or regeneration during storage."

**Commercially dehydrated vegetables: Oxidative enzymes, vitamin content, and other factors,** M. F. MALLETT, C. R. DAWSON, W. L. NELSON, and W. A. GORTNER. (Cornell Univ. et al.). (*Indus. and Engin. Chem., 38 (1946), No. 4, pp. 437-441*).—Essentially noted above.

Some changes which occur in the carbohydrates of sweetpotatoes when they are dehydrated, blanched and dehydrated, or baked (*South Carolina Sta. Rpt. 1945, pp. 68-69*).—Moisture, dextrose, sucrose, and starch were determined in sweetpotatoes prepared primarily for livestock feed by (1) slicing and dehydrating at 70° C.; (2) slicing, blanching in steam at 15 lb. pressure for 30 min., followed by dehydrating at 70°; and (3) baking whole for 1 hr. at 150°. The data presented indicate that "the greatest changes in composition occurred when the sweetpotatoes were blanched or when they were baked. The principal change was a reduction in the starch content and an increase in the quantity of reducing sugars. The sucrose content was not affected to any considerable extent. There was a large loss of starch, particularly in the case of the 'blanched and dehydrated' sweetpotatoes which is not accounted for, but which may consist of dextrins. The baked sweetpotatoes lost about 25 percent of their weight during baking." The dehydrated sweetpotatoes contained 141γ and the blanched and dehydrated product 82.5γ of carotene per gram.

**Storage of dried fruit: Influence of moisture and sulfur dioxide on deterioration of apricots,** E. R. STADTMAN, H. A. BARKER, E. M. MEAK, and G. MACKINNEY. (Univ. Calif.). (*Indus. and Engin. Chem., 38 (1946), No. 1, pp. 99-104, illus. 6*).—This paper is concerned with the development of quantitative methods for studying the rate of deterioration and the storage life of dried fruit. A colorimetric procedure, involving a visual comparison of 50 percent alcoholic extracts with standardized reference solutions, was developed for determining the relative degree of darkness of dried fruit samples. By this method, the storage life of dried apricots was determined as a function of the SO<sub>2</sub> level and the moisture content.

The influence of moisture on the rate of deterioration of apricots with moisture contents greater than 10 percent was found dependent upon the quantity of oxygen available to the fruit. Increasing the moisture content from 10 to 25 percent caused a 15 to 30 percent increase in the storage life when apricots were kept at 49° C. in an oxygen-free atmosphere. Further increases in storage life were noted when high levels of SO<sub>2</sub> (up to 25,000 p. p. m.) were used, although it did not prevent deterioration. During storage at moderate or high temperatures, the SO<sub>2</sub> content of apricots steadily declined until approximately 65 percent of the initial application was lost, showing that the effect of SO<sub>2</sub> is independent of moisture and temperature between 36.7° and 49°.

**Storage of dried fruit: Gas changes during storage of dried apricots and influence of oxygen on rate of deterioration**, E. R. STADTMAN, H. A. BARKER, V. HAAS, E. M. MRAK, and G. MACKINNEY. (Univ. Calif.). (*Indus. and Engin. Chem.*, 38 (1946), No. 3, pp. 324-329, illus. 6).—"The rate of oxygen consumption is greatly increased by increasing the moisture content over the range 10 to 25 percent, by increasing the partial pressure of oxygen, and by increasing the temperature of storage. Although the rate is completely independent of the sulfur dioxide concentration, 30 to 45 percent of the oxygen consumed is utilized in oxidation of sulfur dioxide to sulfate. At temperatures below 43° C. the shortening of the storage life in the presence of oxygen appears to be due entirely to a lowering of the sulfur dioxide level by oxidation. Under anaerobic conditions carbon dioxide is produced by a nonenzymatic process at a rate which is generally correlated with the rate of darkening. The presence of oxygen increases the rate of carbon dioxide production in relation to darkening. Carbon dioxide formation results in the development of 'swells' in cans of dried fruit which are hermetically sealed. The rate of pressure development varies with the tightness of the pack, the sulfur dioxide concentration, and the moisture content. The development of swells is not observed during the edible storage life of the fruit if the ratio of oxygen to fruit in the cans is sufficiently high or if the fruit is canned in vacuum."

**Storage of dried fruit: Influence of temperature on deterioration of apricots**, E. R. STADTMAN, H. A. BARKER, V. HAAS, and E. M. MRAK. (Univ. Calif.). (*Indus. and Engin. Chem.*, 38 (1946), No. 5, pp. 541-543, illus. 6).—Further experimentation (see above) with the deterioration of dried apricots during storage was made regarding the influence of temperature on the rates of darkening, sulfur dioxide disappearance, carbon dioxide production, and oxygen consumption. The results indicated the undesirability of using high temperatures (60° to 70° C.) to dry fruit to moisture levels below 25 percent. Fruit of lower moisture content should have a final drying period at low temperatures (25° to 40°).

**Dehydrofreezing: New way of preserving food**, L. B. HOWARD and H. CAMPBELL. (U. S. D. A.). (*Food Indus.*, 18 (1946), No. 5, pp. 88-90, illus. 3).—A brief discussion is given of the procedure for combining the space and weight advantage of dehydrated products and the fresh-quality retention of frozen ones through partial dehydration followed by freezing storage. Data are summarized for peas, carrots, asparagus, cherries, boysenberries, apricots, and potatoes.

**Frozen foods**, J. H. CLARK (*New Jersey Stat. Cir.* 500 (1945), pp. 23, illus. 7).—This publication, which supersedes Circular 461 (E. S. R., 89, p. 604), describes and illustrates home freezing cabinets, including the walk-in type, homemade cabinets, holding cabinets, and other types of freezing equipment. Experiments are noted which show that the sugar not only adds sweetness but preserves the fresh-fruit flavor of most fruits, and that ascorbic acid is very effective in

improving the quality and appearance of frozen peaches. The amount of ascorbic acid recommended is 150 mg. dissolved in three-fourths of a cup of sirup, or enough to cover the fruit in a 1-lb. package. A table gives ratings of fruit varieties as to their adaptability for freezing. There is also information on temperatures, packaging, and preparation for freezing of vegetables, poultry, cooked foods, eggs, rabbits and other small game, meat products, and fish and shellfish.

**Freeze-drying holds promise**, J. C. MOYER and E. STOTZ. (N. Y. State Expt. Sta.). (*Food Packer*, 27 (1946), No. 4, pp. 42, 44, illus 1) —Essentially noted from another source (E. S. R., 94, p. 831).

**Precooked frozen foods are boon to housewife: Home freezing of precooked foods prevents waste and provides constant source of nutritious flavorful meals—short serving time between freezer and table important**, F. FENTON. ([N. Y.] Cornell Expt. Sta.). (*Farm Res. [N. Y. State and Cornell Stas.]*, 12 (1946), No. 3, p. 13).—A list of 11 precautions are noted for obtaining successful frozen cooked products. These points are based on experimentation reported earlier (E. S. R., 95, p. 589).

**Freezing foods for home use**, S. KALOGEREAS (*Louisiana Sta. Bul.* 404 (1946), pp. 16, illus. 3).—This bulletin considers the basic principles of preservation by freezing, including a list of products suitable for freezing, freezing methods, suitable containers, preparation procedures, and directions for thawing and cooking of frozen foods.

**Problems in freezing cooked foods**, J. G. WOODROOF. (Ga. Expt. Sta.). (*Quick Frozen Foods*, 8 (1946), No. 9, pp. 90-91, illus 3).—Major problems in the complexity of freezing precooked foods discussed here include the separation of fats in gravies, stews, and sauces; precipitation of certain proteins, such as egg whites, starch breakdowns, as in spaghetti and potatoes; and loss of fresh flavor and aroma due to oxidation.

**Moisture losses of vegetables during steaming, quick freezing, and packaging**, J. E. NICHOLAS, G. OLSON, G. V. STARR, and T. U. CONES. (Pa. Expt. Sta.). (*Agr. Engin.*, 27 (1946), No. 6, pp. 263-268, illus. 4).—This study, conducted to determine whether moisture losses in products frozen before packaging were small enough to warrant recommending this type of freezing, included tests on carrots, green beans, broccoli, peas, asparagus, beets, and spinach. Percentage moisture variations were determined after steaming and after freezing, and total percentage moisture variations were calculated, ranging from an average of 20.27 percent loss in spinach to an average 1.40 percent gain in broccoli. Unpackaged products froze from approximately 9 to 13 times faster on plate at  $-0.5^{\circ}$  F. and 23 to 53 times faster in an air blast at  $-9.3^{\circ}$  than packaged products at approximately equal temperatures.

"It was concluded that the method of freezing products before packaging may be recommended for carrots, green beans, broccoli, peas, asparagus, and beets because of the relatively small moisture losses and the great reduction in the time required for freezing. This method was not found satisfactory for spinach because of the difficulty in packaging the frozen product. The high percentage loss for spinach was, however, in steaming and chilling and not in freezing."

**Effect of freezing rate on vegetables: Appearance, palatability, and vitamin content of peas and snap beans**, F. A. LEE, W. A. GORTNER, and J. WHITCOMBE. (N. Y. State Expt. Sta. and Cornell Univ.). (*Indus. and Engin. Chem.*, 38 (1946), No. 3, pp. 341-346, illus. 4).—Five different rates of freezing were employed, ranging from very rapid (by means of liquid air) to very slow (in an insulated box), to study the effects of freezing rates on the quality of vegetables. Peas and snap beans were blanched, frozen, and stored at  $-6^{\circ}$  F.

for 6 mo. Analyses were made (on raw, blanched, and frozen samples after 6 months' storage and after cooking) for ascorbic acid, carotene, and thiamine, with riboflavin being run on peas only. Significant differences in vitamin content were not found from the rates for freezing studied, nor were differences in taste and texture observed with the exception of those frozen in liquid air, which were somewhat softer in texture. Photomicrographs showed that the slower the rate of freezing, the larger the ice crystals; but in the corresponding thawed samples, these differences disappeared and damage was not apparent.

**Home freezing of popular vegetables:** Lima beans, corn on the cob, green soybeans are general favorites—maturity important factor in insuring satisfactory results, F. A. LEE. (N. Y. State. Expt. Sta.). (*Farm Res. [N. Y. State and Cornell Stas.]*, 12 (1946), No. 3, pp. 2, 3, illus. 1).—Suggestions are included for freezing suitable varieties of corn on the cob, lima beans, and green soybeans. Scalding periods according to size of the ears are recommended for corn on the cob.

**Freezing of California fruits—apricots,** L. HOHL and J. SWANBURG. (Univ. Calif.). (*Food Pucker*, 27 (1946), No. 4, pp. 37–38, 68, 70, 72, illus. 1).—Commercial procedures and experimental studies on the processing of apricots for freezing are described. The advantages and disadvantages of each method are enumerated and recommendations are made on the basis of the findings. Steam blanching for a sufficient period of time to inactivate the enzymes, followed by cooking, yielded good results, although sirup blanching was theoretically favorable. Dipping apricots into  $\text{SO}_2$  or sodium bisulfite solution containing  $\text{SO}_2$  (4,000 p. p. m.) for 4 min. was found to give satisfactory results for fruit frozen in halves. Fruit treated in this manner was found to have an  $\text{SO}_2$  content of 50 to 75 p. p. m.

The best results with the use of ascorbic acid as an antioxidant were achieved by using equal weights of fruit and 40° Brix sirup containing 0.1 percent ascorbic acid. Apricots packed in sufficient sugar sirup to cover the fruit required a minimum of antioxidant to retain good color.

Preparation of apricot puree consisted of steam blanching the whole or halved fruit for a minimum time for enzyme inactivations, cooling in air, pitting, and sieving through a 0.04-in. screen in a tomato juicer.

**Tests prove best methods of citrus heart freezing,** A. L. STAHL. (Fla. Expt. Sta.). (*Quick Frozen Foods*, 8 (1946), Nos. 6, p. 59; 7, p. 94).—Silver Cluster, Duncan, Excelsior, Florida common, Marsh Seedless, and Thompson Pink varieties of grapefruit were tested for their value in freezing and were found to be satisfactory in the order named. The effects of the methods of preparation on the frozen product were studied, and the best samples were obtained using precooled fruit (without the use of lye or hot water) and peeled either mechanically or by hand, then immediately subjected to a slight vacuum, broken with  $\text{CO}_2$  gas just before packaging. Sugar sirups produced better results than dry pack. Deaeration proved to be advantageous, as did the use of ascorbic acid as an antioxidant. Results indicated that a storage temperature around 0° F. was preferable to others tested. The glass cup and tin can were found to be more effective than other types of packaging because of their ability to hold the fruit in vacuum. Oranges, tangerines, and mixed orange and grapefruit packs were also found to be satisfactory when treated with the above procedure.

**Freezing experiments on strawberries,** E. A. FIEGER, C. W. DUBOIS, and S. KALOGEREAS. (La. Expt. Sta.). (*Fruit Prod. Jour. and Amer. Food Mfr.*, 25 (1946), No. 10, pp. 297–301, illus. 1).—"Experiments on freezing strawberries with various amounts of dry sugar and sugar sirup were conducted in connection with various treatments of the fruit and methods of freezing. Chemical, physical,

and organoleptic examinations were made on the samples after 16 to 19 months' storage at 0° F.

"Slicing of strawberries facilitated absorption of sugar, resulting in better retention of flavor during the storage period. The addition of dry sugar gave a much better product than the use of sugar sirup. Addition of sugar has no effect on retention of color of strawberries when frozen and stored at 0°. Delayed freezing after addition of dry sugar resulted in a poorer product than those which were frozen immediately after adding the sugar. The best proportions of sugar to strawberries by weight lay between 1 : 4 and 1 : 5 depending on the preference of the individual."

**Frozen blueberries: Home processing and use, M. E. KIRKPATRICK.** (U. S. D. A.) (*Jour. Home Econ.*, 38 (1946), No. 5, pp. 291-292).—Cultivated blueberries of the Scammell and Jersey varieties, as well as some seedlings, were frozen whole for dessert use; others were made into puree and frozen. Part of the whole berries were packed without pretreatment and after evaluation were found to have a more natural fresh flavor than the berries which were scalded in steam for 1 min. before freezing. Sugar sirup or dry sugar packed blueberries had qualities of freshness superior to those frozen without sugar. Preliminary scalding was found unnecessary for berries made into puree, and fresh flavor was maintained over a storage period of several months if they were sweetened before freezing.

**Investigations on the freezing storage of figs, H. M. REED.** (Tex. Expt. Sta.). (*Quick Frozen Foods*, 8 (1946), No. 7, pp. 84-85).—Investigations were made to study the possibility of freezing ripe unpeeled Magnolia figs and the effect of blanching in steam at atmospheric pressure on their keeping quality. Comparative quality ratings were made with other varieties, and Royal Vineyard, Dr. Hoggs Clare, and Reculver figs gave good quality frozen packs. The peeled Magnolia figs were better in appearance and flavor and were less desirable in texture than blanched or unbalanced unpeeled figs. Blanching for 1.5 min. or longer tended to decrease the flavor. There was a loss in the average quality rating of the Magnolia figs as the time of storage increased, with the greater loss occurring after 6 months of storage.

**Testing the sealing qualities of jar rings, E. H. DAWSON, J. A. LORR, and D. E. SHANK.** (U. S. D. A.). (*Jour. Home Econ.*, 38 (1946), No. 5, pp. 287-290).—Methods were developed to determine the sealing performance of jar rings under home canning conditions. Two tests for leakage were employed, one being based on the reaction between barium hydroxide solution within the jars and tannic acid solution in the cooling, and the other on spoilage in a food mixture within the jars after immersion in an inoculated bath. Jar rings of identical composition showed less vacuum with the shoulder-seal jars than the top-seal types, ranging from 24 to 26 in. The sealing quality of the jar rings of different composition was determined, and under the conditions of the barium chloride tannic acid test the shoulder type seal resulted in a larger number of "leakers" than did the top seal. Bacteriological tests of the gasket performance showed a few failures with use of jar rings of the top-seal type and a larger number with the shoulder-seal ring.

**Canned vegetable soybeans. Chemical and nutritional studies, A. KRAMER, C. H. MAHONEY, E. STEPHENSON, and A. L. MARKS.** (Md. Expt. Sta.). (*Food Packer*, 27 (1946), No. 5, pp. 47-48, 50, 52, illus. 2).—Essentially noted elsewhere (E. S. R., 94, p. 533).

**A comparison of some tomato varieties for preserve making, C. W. CULPEPPER, J. S. CALDWELL, and M. C. HUTCHINS.** (U. S. D. A.). (*Fruit Prod. Jour. and Amer. Food Mfr.*, 25 (1946), Nos. 9, pp. 263-267, 269; 10 pp. 302-305,

309, 314-315).—Preserves employed in the varietal comparisons were made by mixing 60 parts of fruit and 40 parts sugar, and concentrating to a solid content of 68 percent. The products were sealed into glass containers while hot and stored in darkness at 70° F. for 6 mo. At the end of this time, colors of all samples were determined by matching with the Maerz and Paul color standards; consistency or viscosity measured by means of a penetrometer or consistometer; and scores made for flavor, texture, and comparative desirability.

The varieties ranking highest in comparative desirability were Principe Borghese, San Marzano, Red Pear, three strains of Yellow Plum, Rutgers, and Hybrid 178. A second group rated slightly less desirable: Beefsteak, Garden State, Marglobe, Pan American × Rutgers No. 16, Ponderosa, Potato Leaf B203, Santa Clara, and one strain of Yellow Plum. The other varieties (29 examined) received scores of good to fair.

Large fruited varieties disintegrated in boiling water, and their products were lower in viscosity and thinner in consistency than those of the small-fruited types. Other than these principal differences, however, products from both types compared favorably in color, texture, flavor, and general desirability. Tomatoes of all varieties showed low solids content and their pectin was destroyed in processing, so that larger percentages of fruit in the preserve mixture were necessary in order to obtain a desirable consistency. The authors suggest that the tomatillo could be advantageously used in making conserves as a base to which other fruits of more pleasing flavor could be added.

Use of wetting agents added to lye solutions for peeling peaches (*South Carolina Sta. Rpt. 1945, pp. 38-39, illus. 1*).—Three commercial wetting agents reduced the time necessary for the peaches to remain in the reaction chamber under actual operating conditions from 20 to 25 percent during an 8- to 10-hr. working period. The data presented emphasize that an increase in the speed of the peeling process increased the capacity of the peeling equipment, and second, a decrease in peeling time resulted in less cooking and softening of ripe peaches.

Oxidation and its control, E. H. WIEGAND. (Oreg. Expt. Sta.). (*Quick Frozen Foods*, 8 (1946), No. 9, pp. 81-83, 92, illus. 6).—Anti-browning agents used to prevent surface browning in peaches and apricots are reviewed. These include 0.10 percent thiourea, 5 percent sodium chloride, 30 percent or higher of sugar sirup, 1 percent sulfurous, 0.01 percent hydrochloric, or 2 percent citric and ascorbic acids, and heat to 180° F. or higher. In summarizing the work done to prevent oxidation in the freezing of these products, the author points out other essential considerations such as speed in handling, maturity and variety of the fruit selected, freezing temperatures, and packaging.

Polyphosphates as aid in home jellymaking, G. L. BAKER and G. M. GILLIGAN. (Del. Expt. Sta.). (*Jour. Home Econ.*, 38 (1946), No. 6, pp. 348-352, illus. 1).—This paper discusses the use of polyphosphates in the extraction of fruit juices for home jellymaking purposes. Experiments indicate that this use makes it possible to increase the pectic quality of certain fruit-juice extracts so that they have a relative viscosity of 12 or more (measured by the Ostwald pipette). A viscosity of 12 to 25 indicates that the ratio of sugar to fruit juice can be raised to 1.5 to 1, the ratio necessary for a quick-boil jelly. For viscosities greater than 25, it is recommended that the juices be diluted with water, enabling the sugar to dissolve more readily in a short-boil method.

Commercial jellymaking aided by polyphosphates, G. L. BAKER and G. M. GILLIGAN. (Del. Expt. Sta.). (*Food Packer*, 27 (1946), No. 6, p. 56).—The application of polyphosphates to the extraction of juices from apples and to a mixture of oranges and lemons for commercial jellymaking is discussed.

**Advances in olive-processing methods in California and abroad**, W. V. CRUESS. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Food Mfr.*, 25 (1946), No. 8, pp. 237-241, illus. 2).—An address presented at the 1946 Olive Growers' Conference, Lindsay, Calif.

**Spoilage and other microorganisms of wine**, W. V. CRUESS. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Food Mfr.*, 25 (1946), Nos. 8, pp. 229-231, 250; 9, pp. 260-262, 285).—The effects of bacteria or yeast attacking wines improperly prepared and stored are reviewed here. Film yeasts, which precede vinegar bacteria and cause a flattening of the flavor and bouquet, may be prevented if storage tanks and casks are completely filled and sealed at all times. Wine yeast (*Saccharomyces ellipsoideus*), a frequent cause of clouding and fermentation of bottled sweet, unfortified white wines, is controlled by means of pasteurization and high concentrations of SO<sub>2</sub>. Acetification of musts, spoilage by lactic acid bacteria, tourne spoilage, bitter ferment, slimy spoilage, tartrate-destroying bacteria, "hair bacillus" of wine, and malic acid-destroying bacteria are also discussed.

**The new interpretation of sanitation**, F. W. FABIAN. (Mich. State Col.). (*Canner*, 103 (1946), No. 2, pp. 12, 14, 16).—This is an address presented to the National Pickle Packers Association.

**Nutritive value of the U. S. food supply**, F. CLARK and J. B. McCAY. (U. S. D. A.). (*Jour. Home Econ.*, 38 (1946), No. 6, pp. 333-337).—This rough estimate of the food intake of the population is based on surveys of family food consumption in different regions and net production figures representing total food supplies available for civilian consumption. The resulting figures represent the average quantities of food that enter the Nation's kitchen for each person each year if the food supply were equally divided among all the people. Estimates of the nutritive value of the national food supply indicate that there is enough food in the United States for everyone to have the nutrients needed for maintaining health. A comparison of the nutrients available in 1935 to 1939 with those in 1945 indicate these increases: Calories 2 percent, protein 14, calcium 22, iron 29, vitamin A 24, thiamine 47, riboflavin 39, niacin 40, and ascorbic acid 22 percent.

**Food preparation equipment of small town families**, D. DICKINS (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), No. 4, p. 7).—The information reported pertains to the kind of equipment used by small-town families of Mississippi. How the kinds and amount of equipment vary with the residence and factors relating to good preparation equipment are discussed.

**Influence of cooking processes on food nutrients: A compilation of abstracts**, W. J. PETERSON and H. B. PRESSLY (*North Carolina Sta. Tech. Bul.* 81 (1946), pp. 133+).—This compilation, prepared as part of the National Cooperative Project, Conservation of Nutritive Values of Foods, brings together from *Chemical Abstracts*, *Experiment Station Record*, and *Nutrition Abstracts and Reviews* over the period from January 1934 up to July 1945, abstracts of all studies bearing on the effect of cooking, whether on large, small, or experimental scale, on the nutritive value of food. Progress reports of the National Cooperative Project and other material not covered by these journals was abstracted by one of the authors of the compilation. Use of the compilation, in which the abstracts are arranged alphabetically by commodities, is facilitated by complete indexes by commodities, by authors, and by nutrients as well as a further author index by commodities.

**Nutrients consumed by army students at the University of Missouri**, L. M. FLYNN and A. G. HOGAN. (Mo. Expt. Sta.). (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 1, pp. 8-14).—Analyses were made to determine the average daily

intake of nutrients in food served during 1 week. Laboratory tests yielded the following average values for nutrients served per man per day: Calories 3,692, protein 155.7 gm., ether extract 108.6 gm., crude fiber 8 gm., sugars and starches 515.9 gm., total ash 35 gm., calcium 2.1 gm., phosphorus 2.7 gm., total vitamin A 22,517 I. U., vitamin A from carotene 17,804 I. U., thiamine 2.4 mg., riboflavin 3.7 mg., niacin 28.6 mg., reduced ascorbic acid 79.7 mg., and total ascorbic acid 117.9 mg.

Under conditions of the study, processing caused a loss of less than 10 percent of the carotene and vitamin A in the raw food; thiamine loss was approximately 10 percent and niacin loss 13.5 percent; loss of riboflavin was within the experimental error. The total loss of ascorbic acid (total) was 23 percent, with 40 percent of the original values obtained from raw foods such as citrus, which was not affected by processing; loss of total ascorbic acid from other fruits and vegetables in kitchen processing was approximately 40 percent.

**Dietary study of Cornell University women, C. M. YOUNG.** (Cornell Univ.). (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 1, pp. 25-28).—This paper reports the results of an investigation conducted in 1942-43 to gather facts relative to the dietary habits of university students. Observations were made of groups of ten women students living under five different circumstances: In a supervised dormitory, in a sorority house, on different campus-controlled cottages with meals served in a central dormitory, in private homes where students work for room and board, and in a graduate house in which residents were free to choose their own eating places. An examination of individual weekly averages showed that for all nutrients the intakes of all women were within the figures used for minimum requirements, which were taken as two-thirds of the National Research Council's recommendations. The one sorority group represented had the lowest intake of all nutrients calculated, and the graduate student group had the next poorest showing. The average figures for the two university supervised groups and the board groups showed satisfactory intakes of all nutrients. An investigation of the intake of specific foods in the food records showed no one who did not drink at least some milk every day—93 percent drank at least one glass. About two-thirds of the women ate one or more servings of meat daily; one-fifth did not eat even one egg during the entire week—the remaining four-fifths ate at least one to three per week; only one-third had as much as one serving of whole grain cereals per day; 95 percent had at least one serving of fruit per day, and about one-half had had two or more; three-fourths had two or more servings of vegetables per day—more than one-third had three or more.

**Meat in the diet of pregnant women, R. M. LEVERTON and T. J. McMILLAN.** (Nebr. Expt. Sta.). (*Jour. Amer. Med. Assoc.*, 130 (1946), No. 3, pp. 134-136, illus. 1).—The study reported here tests the effectiveness of the recommendation to "eat plenty of meat—a generous serving at least twice a day." The 33 women who participated in the study throughout the entire period from 4 mo. before delivery until 3 mo. after delivery were grouped in 11 sets of matched partners. In each set, one woman received as a daily supplement to the freely chosen diet a 5-oz. serving of meat; another woman received a vitamin B complex supplement furnishing 2 mg. of thiamine, 1 mg. of riboflavin, 20 mg. of niacin, and other factors of the complex; and the third partner, serving as a negative control, received no supplement. The average daily protein intake on the freely chosen diets was 58 gm.; this was raised to 83 gm. in the group receiving the meat supplement. Hemoglobin values and red blood cell counts at 1 mo. after delivery both showed increases of 20 percent over initial values in the group receiving the meat supplement as compared with 7- and 10-percent increases, respectively, for women receiving the B complex supplement and 4- and 12-percent increases, respectively,

in the control group. These results and clinical observations throughout the study suggest that a generous meat intake during pregnancy is effective in increasing hemoglobin and red cell concentration, avoiding edema, and promoting lactation.

**The nutritive status of women in the fifth and sixth decades.**—**I, Metabolism of calcium, nitrogen and phosphorus** (*Iowa Sta. Rpt. 1945, pt. 1, pp. 264-265*).—This preliminary report of a study by P. P. Swanson et al. indicates that data to date have been obtained on 10 subjects in this age group. These older women drank only 1 cup of milk daily when living on their customary self-chosen diets. With additional milk, the intake of Ca, P, and N increased and the retention of each nutrient became greater. These subjects needed a daily intake of 0.8-1.0 gm. Ca and 1.3 gm. P, and a daily N intake of 1 gm. per kilogram body weight. One pt. of milk daily was needed to provide enough of these constituents to establish equilibrium.

**Relation of diet of Florida school children to tooth and bone structure** (*Florida Sta. Rpt. 1945, p. 71*).—This is a brief summary report by O. D. Abbott and R. B. French of the findings of roentgenological and dental examinations of Florida school children in certain schools observed in the period 1941-45. Study of the 453 roentgenograms taken at the beginning of the study in children in six schools in Marion County and the Day School in Lafayette County indicated that approximately 70 percent of the children 6-10 yr. of age had various defects and some degree of retarded development of the wrist bones. In about 10 percent of the cases, one to three bones were missing entirely. In 1941 the incidence of caries in two schools were 85 and 79 percent, respectively, while the incidence of gingivitis in the same schools was 73 and 76 percent, respectively. The children showing severe caries and delayed maturation of the wrist bones were given special diet supplements, and with improved diet, yearly roentgenograms on selected cases showed progressive improvement of the wrist bones. In some cases, ossific centers which the year before appeared as mere shadows or points had increased to a semblance of a bone and in many cases calcification apparently was accelerated. Also, the incidence of caries decreased and by 1944 was rare in both schools, where gingivitis likewise had been greatly decreased. Even in 1945, when transportation difficulties and high costs of citrus fruits had prevented the use of these fruits in optimum amounts in one school, there were still no severe cases of gingivitis.

**Improving the diet by the use of wheat substitutes and green vegetables,** O. SHEETS (*Miss. Farm Res. [Mississippi Sta.], 9 (1946), No. 3, pp. 1-2*).—Data are given on the nutritive composition of different kinds of flour, and comparisons are made with that of substitute foods. Degerminated cornmeal has as high a nutritive value as unenriched white flour, with the exception of the protein content. Potatoes, because of their high moisture content, have a lower nutritive content in most respects than white flour, but served in large quantities would be comparable and, at the same time, furnish considerable vitamin C. Mature beans and peas have approximately the same caloric value as flour, and are richer in several nutrients.

**Human starvation and its consequences,** A. KEYS. (Univ. Minn.). (*Jour. Amer. Dietet. Assoc., 22 (1946), No. 7, pp. 582-587, illus. 2*).—"Effects of an extensive experiment in semistarvation on 32 human volunteers who lived on a European type of famine diet for 6 mo. and were subsequently studied during rehabilitation on various fixed 'relief' diets are reported. Preceding the period of undernutrition there were 3 mo. of control and standardization studies. The men lived in the laboratory and maintained a fixed regimen corresponding to light industrial work. A daily intake of slightly more than 3,150 calories was needed for balance in the control period; the famine diet averaged 1,760 calories

including 49 gm. of proteins and fairly reasonable amounts of vitamins and minerals.

"In semistarvation there developed progressive and severe weakness, depression, fatigue, anemia, bradycardia and edema. There were small effects on coordination, speed, and plasma proteins. There were no adverse effects on vision, hearing, or general intellectual capacity. The mean weight loss was 37 lb., amounting to 24 percent of the original body weight. The true weight loss, corrected for edema and hydremia, was about 50 lb., of which fat accounted for about 30 percent. There were few if any unequivocal signs of vitamin deficiencies.

"In rehabilitation it was found that only diets averaging over 2,500 calories daily allowed significant recovery, and with the best diet, averaging about 3,500 calories, recovery was only about 50 percent in 3 mo. Full recovery required 8 to 12 mo. Extra vitamins and proteins had little apparent effect on the rate or course of recovery."

**Carbohydrate metabolism**, S. SOSKIN and R. LEVINE (*Chicago: Univ. Chicago Press, 1946, pp. 315+*, *illus. 75*).—This volume, intended to serve as a reference text for the teaching of carbohydrate metabolism to students of physiology, biochemistry, and medicine, is presented in five parts dealing with (1) the biochemistry and energetics of carbohydrate metabolism, (2) introductory physiological considerations, (3) critical survey of the classical criteria of diabetes, (4) the role of the endocrine glands in carbohydrate metabolism, and (5) integration of physiological and clinical aspects. The volume also deals in considerable detail with certain aspects of protein and fat metabolism. The selected bibliographical references associated with each chapter total more than 1,200 in number.

**The effect of processing on the biological value of eggs** (*Iowa Sta. Rpt. 1945, pt. 1, pp. 260-263*).—This progress report by P. P. Swanson, G. F. Stewart, et al., on the nutritive value of the proteins of dehydrated eggs indicates that the biological efficiencies as tested with rats by Mitchell's balance method were 109, 111, and 108 percent for dehydrated whole eggs, egg yolks, and egg whites, respectively; that these proteins were even more efficient than those of the animal's own tissues (liver, muscle); and as efficient as a mixture of 10 amino acids essential to the nutrition of the rat. Methionine tested separately was found to be as efficient as were the whole egg proteins or the mixture of 10 amino acids. When the calories furnished by the diet were only 50 percent of the normal, a break in the utilization of the egg proteins occurred.

**Modifications in blood, urine, and tissues of rats affected with pregnancy disorder induced by feeding diets containing pork** (*Iowa Sta. Rpt. 1945, pt. 1, pp. 258-259*).—Studies by P. P. Swanson et al., directed toward determining the nature of dietary deficiencies involved in the toxemias of pregnancy, particularly as observed in rats fed on a diet containing autoclaved pork muscle (E. S. R., 94, p. 544), showed that certain abnormalities of carbohydrate and protein metabolism occurred in the pregnant, pork-fed rats. Specifically, the glucose tolerance curves of these rats were diabetic in character, especially in the pregnant, pork-fed rats showing toxic symptoms. Nonprotein nitrogen and urea increased in the blood and plasma proteins decreased as toxemia developed. It was observed that these characteristic metabolic abnormalities in the toxic rat did not appear until the animal was acutely ill.

**Influence of manganese intake upon urea excretion**, J. T. SKINNER and J. S. McHARGUE. (Ky. Expt. Sta.). (*Ky. Acad. Sci. Trans., 11 (1943-44), Nos. 3-4, pp. 47-50*).—"Urea excretion was determined on rats at varying levels of food consumption and on low, medium, and high intakes of manganese. In the manganese groups, the urea excretion ranged from 82 to 139 and averaged

101 percent of that excreted by the respective pair-mate controls. In 7 out of 18 comparisons, it was observed that the manganese-fed rat excreted more urea than its pair mate on a low-manganese ration."

**Vitamin studies on lima beans.** J. F. EHEART, R. C. MOORE, M. SPEIRS, F. F. COWART, H. L. COCHRAN, O. A. SHEETS, L. McWHIRTER, M. GIEGER, J. L. BOWERS, P. H. HEINZE, F. R. HAYDEN, J. H. MITCHELL, and R. L. CAROLUS (*Virginia, Georgia, Mississippi, South Carolina, and Virginia Truck Stas. and U. S. D. A. Region. Vegetable Breed. Lab., South. Coop. Ser. Bul. 5 (1946), pp. 24, illus. 3.*).—This study was conducted as one part of the Southern cooperative nutrition project on variations in the composition and nutritive value of vegetables grown in the South. The experiment, designed to admit of statistical analysis of the data, was cooperatively planned and executed, with the object of determining the effects on nutritive value of such factors as variety, location, bean maturity, plant maturity, storage, and cooking. This report presents the details of the experimental plan, the chemical methodology, the statistical methods, and the experimental results.

The Carolina Sieva pole beans and the Henderson bush beans, each grown at the six locations from a common seed source and under similar conditions of cultivation, showed no varietal differences in thiamine and riboflavin content. The two varieties differed only in respect to ascorbic acid content, the pole variety being about 17 percent higher in this vitamin than the bush variety. The authors indicate, however, that the pole variety cannot be recommended too highly as being superior to the bush variety on the basis of this difference, particularly since it was smaller after cooking and since the differences in thiamine and riboflavin were not significant. Highly significant location differences were obtained for all three vitamins; likewise, between years (1943, 1944, 1945) at the same location highly significant differences were obtained for ascorbic acid. Thiamine contents (in 1945) varied from 713.2  $\mu\text{g.}$  per 100 gm., dry basis, at Experiment, Ga., to 1,108.2  $\mu\text{g.}$  at Charleston, S. C.; and riboflavin varied from 208.3  $\mu\text{g.}$  at State College, Miss., to 359.0  $\mu\text{g.}$  at Experiment. Ascorbic acid varied from 55.5 mg. per 100 gm., dry basis, at Charleston in 1943 to 112.9 mg. at Experiment in 1944. Ascorbic acid, thiamine, and riboflavin contents decreased with bean maturity, but the decrease was greater for ascorbic acid and riboflavin than for thiamine.

In these experiments, the beans, shelled from the freshly harvested pods, were separated into three bean maturity lots, representing (1) immature green beans, one-half to two-thirds mature size and green in color; (2) mature green beans, mature in size and green or greenish-white in color; and (3) mature white beans, mature in size and white in color. Analyses of beans harvested at different stages of maturity of the plant itself gave no evidence that age (maturity) of the plant affected the ascorbic acid, thiamine, or riboflavin contents of the beans as long as maturity of the beans remained constant.

Analyses of beans stored under various conditions showed that beans were more nutritious in the fresh, unstored state than when they were stored. The best method of storage was in the pod, under refrigeration, only 5 percent of the ascorbic acid thus being lost in 48 hr., while shelled beans similarly stored lost 16 percent. Losses of ascorbic acid were much greater during room storage than during refrigerator storage, 39 percent being lost in the 48-hr. room-stored samples while 67 percent was lost in the shelled beans similarly stored. Greater losses of ascorbic acid occurred in the first than in the second 24 hr. when shelled beans were stored at room temperature. The combination of room storage and bean maturity affected the ascorbic acid content of the beans much more than it did the thiamine and riboflavin contents. In general, thiamine and riboflavin contents of the beans were not influenced by room storage for as long as 48 hr.

Cooking of the beans in experimental lots of 50 gm. dropped into 100 cc. of boiling distilled water brought about large cooking losses. When the beans were thus cooked for  $\frac{1}{2}$  and 3 hr., respectively, about 82 and 59 percent of the ascorbic acid originally present in the raw beans remained in the cooked beans; however, when the beans were room-stored and then cooked for these two periods, respectively, the cooked beans retained only 23 and 12 percent of the ascorbic acid initially present in the fresh, raw beans.

"In order to obtain the highest nutritive value with respect to vitamin content from lima beans, the following recommendations, in light of the present study, may be listed: (1) Harvest the beans at the earliest marketable stage of maturity possible; (2) cook the beans as soon after harvesting and for as short a time as possible; (3) if the beans are not cooked immediately after harvesting, leave them in the pod and store them in the refrigerator; and (4) do not shell the beans until immediately before cooking."

**Vitamin content of frozen peas, green beans and lima beans, and market-fresh yams prepared in a Navy mess hall, A. M. BRIANT, V. E. MACKENZIE, and F. FENTON.** ([N. Y.] Cornell Expt. Sta.). (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 7, pp. 605-610).—Thiamine, riboflavin, and ascorbic acid were determined in vegetables before and after several methods of large-scale cooking and holding procedures carried out in a Navy mess hall.

The results of this study are given as "apparent retentions", calculated on the basis that the content in milligrams per 100 gm. raw frozen vegetable was 100 percent, thus assuming that there was no change in weight and moisture contents during the different preparation procedures. The thiamine content of 100 gm. uncooked frozen peas was 0.29 to 0.35 mg.; cooked peas, 0.20 to 0.33 mg.; and peas after cooking, 0.16 to 0.24 mg. The corresponding riboflavin content was 0.078 to 0.10 mg.; 0.071 to 0.082 mg.; and 0.067 to 0.081 mg., respectively. Ascorbic acid content was 7.7 to 15 mg.; 5.2 to 9.5 mg.; and 4.1 to 7.8 mg., respectively.

The concentration of these vitamins in the green beans, lima beans, and yams after cooking and holding covered a similarly wide range, due to the wide variation in the details of the cooking procedure. In general, the vitamin concentration decreased with the increase in the length of the holding period.

**Vitamin retention in frozen peas and frozen green beans in quantity food service, A. M. BRIANT, V. E. MACKENZIE, and F. FENTON.** ([N. Y.] Cornell Expt. Sta.). (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 6, pp. 507-510).—In this paper, an outgrowth of the preceding study, frozen green peas and frozen green beans were defrosted for 3 hr. at room temperature before cooking by three quantity methods. The vegetables which were boiled in tap water showed the lowest thiamine and riboflavin retention, while the steamed peas and beans showed the highest retention. Steamed peas, however, showed the lowest retention of ascorbic acid, and a further loss occurred during holding. All the thiamine and riboflavin lost from the vegetables during cooking was found in the cooking water, while holding them brought about no change.

The drained cooked peas retained from 66 to 94 percent of the original thiamine content present in the uncooked frozen peas. Other percentage retentions were riboflavin 67 to 98 percent and ascorbic acid from 34 to 69. The corresponding figures for the green beans were thiamine from 55 to 95 percent, riboflavin from 56 to 93 percent, and ascorbic acid from 37 to 55 percent.

**Effects of canning and drying on the carotene and ascorbic acid content of chile, E. M. LANTZ** (*New Mexico Sta. Bul.* 327 (1946), pp. 21, illus. 4).—Following earlier work on the carotene and ascorbic acid contents of hot and paprika-type peppers (*E. S. R.*, 94, p. 408), the study here reported was undertaken to determine the amounts of these vitamins in home or commercially

canned or dried green and dried ripe (red) peppers (*Capsicum annuum*) of the hot variety. The Spanish word "chile" is used in this bulletin to refer to these hot varieties.

Peeled, seeded, and precooked green chile (as obtained by holding the pricked pods in hot oil at 350°–400° F. until the skin blistered and could be peeled off) was canned in a pressure cooker with processing times of 20–25 min. at 240°. Analyses of samples before and after processing indicated that during canning the green chile retained practically all of the carotene of the prepared, uncanned chile and about two-thirds of the ascorbic acid value. Sampling difficulties were considered to be responsible for certain anomalous calculated carotene retentions of more than 100 percent. Carotene values for the freshly canned products averaged about 83 mg. per 100 gm., and ascorbic acid values about 309 mg. per 100 gm. There was a slight gradual loss of both vitamins during storage of the canned product.

The artificial drying of either green or red chile was found to offer a number of advantages over the time-honored practice of sun-drying. These include greater attractiveness and palatability of the product, freedom from mold, and the saving of time. With the green chile, artificial drying also improved the vitamin retention. Home-constructed cabinet dehydrators gave a rather more satisfactory product with better vitamin retaining properties than did the simple tank-type, steam-heated dehydrator. A preliminary 10-min. steaming of the peeled, green chile improved the carotene retention but had a slightly unfavorable effect on ascorbic acid retention. Although the use of artificial heat to dry the whole, red chile pods cut the drying time from several weeks to 3 days, it did not materially affect the retention of carotene or ascorbic acid. No method of drying the red peppers yielded a product that could be considered even a fair source of ascorbic acid, although most of the carotene was retained, making them a very concentrated source of that vitamin. Analyses of certain commercially prepared chile products available on the local market showed them to be exceedingly variable in carotene and ascorbic acid content.

**Effect of quantity preparation procedures on vitamin retention:** Canned tomatoes, E. GLEIM, M. ALBURY, K. VISNYEI, J. R. MCCARTNEY, and F. FENTON. (Cornell Univ.). (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 1, pp. 29–31).—

The ascorbic acid, niacin, and carotene content of commercially canned tomatoes was determined and their retention during five heating procedures commonly employed in large-scale food preparation ascertained. These procedures were as follows: (1) Heated in open pan in steamer set at 5 lb. pressure for 15 min., (2) heated unopened in steamer set at 5 lb. pressure for 25 min., (3) heated to 80° C. in stockpot on gas plate (40 to 60 min.), (4) brought to simmer in stockpot (37 to 48 min.) and held 30 min. at a simmer, and (5) brought to simmer in stockpot (29 to 33 min.) and held 3 hr. at a simmer. The ascorbic acid in the total unheated contents of the cans varied from 13.9 to 16.6 mg. per 100 gm., carotene 0.366 to 0.397 mg., and niacin 0.515 to 0.577 mg. per 100 gm. A decrease from 16.6 to 13.9 mg. per 100 gm. occurred during the 2-mo. period of the study, while the thiamine and riboflavin contents, 0.564 and 0.361 mg. per 100 gm., respectively, were so low that cooking losses were not determined. In each of the methods of heating, ascorbic acid tended to become equally distributed between the pulp and liquid and there was a 92 to 94 percent retention after heating by the first method. Prolonged heating was harmful, with method No. 5 showing a 70 to 81 percent loss. Almost three times as much carotene was present in the pulp as in the juice, while none of the described methods of heating caused significant difference in the retention. More niacin was present in the pulp than in the liquid, but during heating this vitamin tended to become equally distributed. An

appreciable loss of niacin occurred during heating by method No. 5 (70 to 81 percent).

**Vitamin content of peas: Effect of freezing, canning, and dehydration,** C. H. MAHONEY, E. P. WALLS, H. A. HUNTER, and L. E. SCOTT. (*Md. Expt. Sta.*). (*Indus. and Engin. Chem.*, 38 (1946), No. 6, pp. 654-657).—Comparable lots of eight varieties of peas were canned, frozen, and dehydrated, and ascorbic acid was determined on the product after a 6-mo. storage period, before and after cooking. Ascorbic acid retention (dry basis) after a 6-mo. frozen storage varied from 46.1 percent for the Pride variety to 71.4 percent for Teton, with an average for the eight varieties of 58.4 percent. The retention in the canned drained peas after the same storage period varied from 41.0 for Pride to 53.4 percent for Teton, with an average of 47.4 percent. The total retention of the canned peas (drained peas plus the liquor) varied from 72.3 percent for Pride to 91.7 percent for Early Harvest, with an average of 79.0. Dehydrated peas contained about one-third as much ascorbic acid as frozen or canned peas; when stored under  $\text{CO}_2$  they had a higher level than those stored under air or in vacuum. After cooking, ascorbic acid retention (dry basis) of the products, compared with the original content, was 58 percent for the canned material, 53 percent for the frozen, and 19 percent for the dehydrated.

Frozen peas showed higher carotene values than those of the canned or dehydrated lots, and thiamine retention for the frozen and canned peas was about two-thirds while dehydrated peas retained one-half of the original content.

**The effect of curing on the carotene and ascorbic acid content of sweet potatoes** (*South Carolina Sta. Rpt. 1945, p. 70*).—Seven varieties of sweetpotatoes, two with white flesh, were analyzed for carotene and ascorbic acid immediately after harvest, and for ascorbic acid after a 10-day curing period. Carotene in the five yellow-fleshed varieties varied from 2.80 to 5.19 mg. per 100 gm. of fresh sample. At harvest, ascorbic acid ranged from 23.16 to 32.62 mg. per 100 gm. fresh basis. At the end of the curing period the values ranged from 15.26 to 23.38 mg. per 100 gm. and represented losses from as low as 6.30 percent in one of the yellow-fleshed selections to as high as 36 and 53 percent in the two white-fleshed varieties, respectively.

**Effect of processing on the carotenoids and vitamin C content of peaches** (*South Carolina Sta. Rpt. 1945, pp. 70-72*).—In continuation of this study (E. S. R., 93, p. 657), 13 canning varieties of peaches were sampled at the cannery before and after lye peeling, and immediately made into blended mixtures for analysis by use of the Waring blender. Two percent  $\text{HPO}_3$  was used as the extractant for the ascorbic acid blend and a mixture of 50 cc. alcohol and 70 cc. hexane for the carotenoids blend. The peaches, averaging 1.52 mg. of total carotenoids and 6.50 mg. ascorbic acid per 100 gm. of fresh sample, showed an average loss of 13.2 and 24.2 percent of these two vitamins, respectively, in the lye peeling process. The lye-peeled peaches packed in 11-oz. portions in a sugar solution in paper cartons and frozen, showed a loss of both vitamins over a 7-mo. storage period, the loss of ascorbic acid in the different varieties varying from 30.2 to 65.8 percent and that of carotenoids from 0.0 to 26 percent. These vitamin losses in the freezing process were much larger than those observed in canning in the case of ascorbic acid, although the reverse was true for the carotenoids.

**A two-year study of the vitamin A potency of Louisiana milk and butter,** H. LEWIS and E. A. FIEGER (*Louisiana Sta. Bul. 405 (1946), pp. 10, illus. 1*).—In this study, conducted as part of the national cooperative butter project, vitamin A and carotene were determined by the chemical methods suggested by the technical committee of the project. These determinations were made on 33 samples of representative creamery and herd milks produced in the State and on 2 of butter

supplied monthly over a 2-yr. period. Data presented in a preliminary report (E. S. R., 93, p. 187) have been recalculated for the present final report, using the factor 4 (rather than  $3\frac{1}{2}$ ) for converting micrograms of vitamin A into International Units of the vitamin.

The monthly averages for the vitamin A in these Louisiana herd and creamery milks and creamery butter are reported for the interval October 1943 through September 1945. The herd milks varied from 1,097 to 3,211 I. U. and averaged 1,977 I. U. per quart over this period; the creamery milks varied from 815 to 2,803 I. U. and averaged 1,616 I. U. per quart; and the creamery butters varied from 6,886 to 22,505 I. U. and averaged 14,445 I. U. per pound. The lower values for the creamery milks are attributed to the standardized adjustment to about 3.8 percent butterfat. Information reported by cooperators furnishing the milk samples told of the type of pasture and its condition, the nature of roughage and concentrate which were fed, and the number of cows which freshened. This supplementary information, considered in conjunction with the analytical data, indicated that the vitamin A values for the dairy products were high when ample green pasture was available and low during the winter and extremely dry summer months. The most striking effect of pasture conditions was shown by grazing cows for 1 or 2 hr. a day on fall-planted oats. The increase in vitamin A potency brought about by the use of supplemental oat pasture varied from time to time but averaged about 33 percent. The grazing of clover pastures was also reflected in increased vitamin A potency of milk from practically all herds, and the combination of clover with supplemental oat pastures resulted in milk more potent in vitamin A than did either forage alone.

**The vitamin A and carotene content of market butter produced in Kansas,** D. B. PARRISH, W. H. MARTIN, F. W. ATKESON, and J. S. HUGHES. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 29 (1946), No. 2, pp. 91-99, illus. 2).—This study, carried out as a part of the national butter project, presents the results of tests made on the vitamin A and carotene potency of butter produced in Kansas during the period July, 1943, through December, 1944. In addition to this phase of the study, certain other data were obtained on butter composition and quality, pasture conditions, and feeding practices in relation to the vitamin A and carotene content.

The 1944 mean annual vitamin A potency was 15,100 International Units per pound, while the period, December to April, was 11,050 I. U., and from May to November, 17,700 I. U. In these respective periods, carotene accounted for 19.6, 14.9, and 21.4 percent of the total vitamin A potency.

"The vitamin A and carotene content of butter produced in different areas of the State and during different months of the year varied with the pasture available. When little or no pasture existed, the values for vitamin A and carotene dropped. Good pasture conditions increased the vitamin A and carotene values to maximum in May and June. During the hot summer weather the values dropped off somewhat, returning to higher levels when pastures improved in the fall of the year."

No correlation between the Nafis color grade and the vitamin content of the butter was found due to the use of artificial colors in the winter months.

**Effect of storage on carotene of plant extracts,** A. R. KEMMERER and G. S. FRAPS. (Tex. Expt. Sta.). (*Indus. and Engin. Chem.*, 38 (1946), No. 4, pp. 457-458).—"During storage, up to 8 mo., of 13 samples of dried grasses and dried foods, the percentage of impurity A increased in the crude carotene fraction. The percentage of  $\beta$ -carotene in the pure carotene fraction decreased in 6 samples and remained nearly constant or increased slightly in the other 7. The percentage of neo- $\beta$ -carotene U in the pure carotene increased in 11 of the samples, and that of neo- $\beta$ -carotene B decreased in 10. The quantity of

impurity A increased in dehydrated carrots up to 14 mo. of storage and in beet greens up to 4 mo. of storage. In all other samples there was a decrease in the amount of impurity A.  $\beta$ -Carotene, neo- $\beta$ -carotene U, and neo- $\beta$ -carotene B decreased in all the samples except beet greens, in which there was a slight increase in neo- $\beta$ -carotene B during the second and fourth months of storage."

**Effect of milling, processing, washing, cooking, and storage on thiamine, riboflavin, and niacin in rice,** M. C. KIK (*Arkansas Sta. Bul. 458 (1945), pp. 60, illus. 6*).—Following an earlier summary of the results of rice protein studies (E. S. R., 87, p 303), the present bulletin brings together in considerable detail the findings of the station on the thiamine, riboflavin, and niacin content of rice. Some of these studies have been reported earlier (E. S. R., 90, p. 135; 92, p. 592). Background information supplied concerns the structure of the rice kernel in relation to the results attained by the milling processes described for the production of brown and polished rice and byproducts, of parboiled milled rice, of unmilled or unpolished rice, and of commercially processed rices including converted, Malekized, Earle processed, and artificially enriched rices. Analytical methods used in the study are presented in detail. In addition, several simplified tests that have been proposed for the determination of thiamine were applied to rice. Of these, a cold or warm extraction with 25 percent KCl in 2 percent acetic acid and subsequent oxidation was found to be a promising short-cut method.

Analytical results obtained showed that, on an average, in the milling of brown rice to white, polished rice 76 percent of the thiamine, 56 percent of the riboflavin, and 63 percent of the niacin were lost. At a 70-percent level in the diet of rats, brown rice was found to be superior to white rice as a source of riboflavin and thiamine and slightly better as a source of pyridoxine and inositol. Rice varieties grown in Arkansas, Louisiana, Texas, and California, the main rice-producing States, showed varietal differences in thiamine and riboflavin, but only slight differences in niacin. Location apparently had a slight influence on thiamine and riboflavin but an insignificant influence on niacin. The data on variously milled and treated samples suggested that losses due to milling could be lessened by (1) a less severe milling, as in undermilling or unpolishing and in the Earle peeling process, or (2) pretreatment of the rice by soaking and steaming as in the Malekiz process or by soaking and parboiling by the modernized method known as rice conversion. As a third alternative, enrichment may be practiced.

Washing of rice preliminary to cooking was found to effect losses of 21, 7, and 13 percent, respectively, of the thiamine, riboflavin, and niacin in brown rice. Washing losses were high in white polished and sprayed enriched rice but smaller again in Malekized, converted, and Earle rice. "As an effect of cooking in all types of rice, small losses were found in the double boiler type of cooking and large losses were found in the open vessel type of cooking. However, even with the latter type of cooking, better retention took place in converted, Earle rice, and brown rice than in white milled rice. These losses were small in rice artificially enriched according to the methods of Fieger and Hoffmann-La Roche."

Cold storage up to 2½ yr. effected no significant losses in thiamine or niacin and only slight losses in riboflavin, whereas storage at room temperature caused appreciable losses which were greater in ground than in whole kernels.

**The nutritional improvement of white rice,** M. C. KIK and R. R. WILLIAMS. (*Ark. Expt. Sta.*). (*Bul. Natl. Res. Council, No. 112 (1945), pp. 76+, illus. 16*).—This bulletin was prepared with the purpose of collecting, "as far as possible, the essential facts that indicate the relative promise of each of the various expedients to improve the quality of milled rice and furnish criteria

for future commercial practice." Consideration is given to rice production and consumption in the Orient, United States, Puerto Rico, and Europe; rice cookery as practiced in these regions and losses of nutrients in rinsing and cooking rice; the nutritive qualities of rice; polished rice and beriberi; proposed corrective measures against beriberi; commercial rice milling by standard and modified procedures; the deterioration of rice in storage from the standpoint of insect attack, rancidity, and losses of nutrients; the parboiling of rice and the increased retention of nutrients effected by application of this treatment prior to milling; the modernized parboiling processes referred to as rice conversion; and the artificial enrichment of rice. The experimental data presented are largely from the Arkansas Station and are based on the studies covered by the above report.

**Effect of methods of cooking fresh and cured pork and of canning fresh pork, on the riboflavin content** (*Kentucky Sta. Rpt. 1945, pp. 9-11*).—In continuation of studies on the vitamin content of pork (*E. S. R.*, 93, p. 661), conducted as part of the National Cooperative Project, Conservation of Nutritive Values of Foods, loin, spareribs, liver, ham, and shoulder cuts from 6-month-old pigs raised under uniform conditions were analyzed for riboflavin; certain aliquots were analyzed in the raw state, others after cooking or canning. For later analyses of cured meat, the left hams and shoulders of half of the pigs were salted, smoked, and stored in a cool dry place. The cooking methods used were those approved by the committee on preparation factors of the national cooperative meat investigations. Riboflavin was determined by the Conner and Straub method.

In general, the cooking loss of riboflavin was found to be less than that of thiamine or niacin; in longer cooking such as in canning there were even apparent increases in riboflavin. This apparent increase in riboflavin was also observed in curing, with further increases upon cooking of the cured meat. Pork liver, raw or cooked, was notably rich in riboflavin as compared with the other two vitamins. The best source of riboflavin in the cooked muscle cuts was boiled shoulder. Poorest was roast loin. These were estimated to furnish, respectively, 227 and 98  $\mu\text{g.}$  of riboflavin in a serving portion equivalent to  $\frac{1}{4}$  lb. of the raw meat.

**Effect of roasting and reheating on the thiamine content of turkey** (*Kentucky Sta. Rpt. 1945, pp. 11-12*).—This study, conducted as part of the National Cooperative Project on the Conservation of Nutritive Values of Foods, utilized eight Broad-Breasted Bronze tom turkeys 6½ mo. old that had been raised on good range with corn and oats fed separately. The birds, with dressed weights of 17-22 lb., were held wrapped in parchment in freezing storage for 7 weeks before sampling and analysis of the paired halves on the raw and cooked basis, respectively. The halves for roasting were placed cavity-side down on the roaster rack, which was covered with parchment paper on which had been placed the halves of gizzard and liver. Each half was roasted to an inner temperature of 190° F. at a constant temperature of 275°.

The raw dark meat in the several birds averaged 66.9 to 87.3  $\mu\text{g.}$  percent of thiamine and the raw white meat 39.1 to 45.1  $\mu\text{g.}$  percent on the moist basis. The raw portions of dark meat next to the skin contained more thiamine than portions extending toward the bones. The same was true of the thiamine content of white meat, but to a lesser degree. The loss of thiamine due to roasting was greatest in the portion just underneath the skin, with an average of 39.3 percent loss in white meat and 54.1 percent in dark meat. After removal of the slices for analysis on the freshly cooked basis, the turkey halves were held in the refrigerator for 24 hr., after which the white meat was removed from the carcass in slices and the dark meat was removed in as large pieces as possible. One portion each

of dark and white meat was analyzed cold, the second portion was heated on a steam table (as in cafeteria service) for 20 min., and the third portion for 50 min. before analysis. "The roasted dark meat extending further in and sampled 24 hr. after roasting without reheating contained more than the sample taken immediately after roasting. When the dark meat of this portion was reheated, about the same loss of thiamine occurred as in the portion just underneath the skin. The slices of roasted white meat that had stood 24 hr. and been analyzed either as cold sliced meat or reheated showed about an equal loss of thiamine, that is from 22.5 to 24.7 percent." The moist, raw gizzard averaged 43.5, 42. percent of thiamine, while the figure for the roast gizzard was 37 percent less than that for the raw. The entire amount of drippings contained from 336 to 2,790  $\mu$ g. of thiamine. Skin had but little thiamine, averaging on the raw moist basis but 24.8  $\mu$ g. percent. Raw liver averaged 205  $\mu$ g. percent of thiamine on the moist basis and showed a loss of 8.9 percent of thiamine due to roasting.

**Ascorbic acid content of food served in a cooperative residence hall for women, M. L. DUNKERLEY and M. M. KRAMER. (Kans. Expt. Sta.).** (*Jour. Amer. Dietet. Assoc.*, 22 (1946), No. 1, pp. 15-19).—Samples were taken for six representative periods, totaling 44 days, during the fall, winter, and spring seasons. Calculations were made to show total ascorbic acid provided per person per day, based on milligrams per 100 grams and per serving of food. All foods containing fruits, vegetables, or milk were studied.

"The ascorbic acid averaged 70.9 mg. per person per day, and ranged from 24.5 to 146.3 mg. In two periods the ascorbic acid supplied was about 15 percent more than the recommended 70 mg. daily. However, during three periods the averages were about 10 percent below this." The daily menus were analyzed as to source and distribution of ascorbic acid—citrus fruit was found to supply one-third and leafy vegetables one-fifth of the total ascorbic acid. There was a wide variation in the cost of different foods supplying ascorbic acid.

**The effects of icing on retention of quality and ascorbic acid in vegetables, M. SPEIRS, E. L. WARREN, F. H. WILSON, and V. G. GREENLEAF. (Ga. Expt. Sta.).** (*Ice and Refrig.*, 111 (1946), No. 1, pp. 19-22, illus. 1).—Samples of asparagus of the Mary Washington variety were obtained from six harvests between April 16 and May 4 in 1945 and from five harvests between April 3 and April 10 in 1946. The results of changes in quality, weight, and ascorbic acid and moisture content for asparagus stored under various conditions are noted.

The quality of asparagus held with heavy icing in a well-insulated chest was excellent for 21 days, while bunches held with moderate icing remained in excellent condition for 6 days. Bunches iced moderately in the daytime and refrigerated at night were in excellent condition for 4 days and good for 6 days. Storage at room temperature in the daytime and cold storage at night, or held at room temperature in water, produced some deterioration in quality. Asparagus samples stored at room temperature in water were fair in quality after 3 days and inedible after 6 days in 1945 and after 5 days in 1946.

Marked changes in weight accompanied losses in quality, except in those cases in which the butts were placed in water. Decreases in ascorbic acid content were rapid during storage under all conditions except heavy icing, in which 81 percent was retained after 5 days storage.

**Effect of storage conditions on ascorbic acid content of kale and cantaloupe, G. M. GILLIGAN and C. W. WOODMANSEE (Delaware Sta. Pam. 23 (1946), pp. 3+).**—Scotch Blue Curled kale, freshly harvested from the field in samples sufficiently large to insure uniformity, was placed under the following storage conditions with the least possible delay: (1) Embedded in and completely covered with chopped ice, (2) placed in a cabinet containing block ice, and (3) left in the

open storage shed. The mean temperatures for these three storage conditions, respectively, were 34°, 40°, and 77° F. These freshly harvested kale leaves (less midrib) averaged 12½ mg. of ascorbic acid per 100 gm. When held in chopped ice the ascorbic acid was very well retained for at least 4 days; after ice refrigeration, there was a loss of 18 percent within 24 hr., 24 percent after 4 days, and 39 percent after 7 days. At room temperature, there was about a 35-percent loss within the first 24 hr., after which the loss was not appreciable until the fourth day. After 7 days at room temperature, the destruction of ascorbic acid was complete and the kale was no longer in a usable state. These data suggest that the fourth day is the critical point in the deterioration of ascorbic acid in kale and that a cool, moist, quiet atmosphere is conducive to the best retention of the ascorbic acid.

The results showed that freshly harvested Jumbo and Hale Best cantaloups, stored under conditions similar to those used for kale, retained their initial ascorbic acid content (27 mg. per 100 gm.) very well for 4 days under any of the storage conditions. In chopped ice, there was practically no loss of ascorbic acid after 7 days; in the ice refrigerator, there was only a slight loss in this period; and at room temperature, there was approximately a 40-percent loss. In the cantaloups as well as in the kale, retention of appearance and palatability paralleled that of the ascorbic acid.

**Relation of environmental and hereditary factors to ascorbic acid in cabbage,** F. G. SMITH and J. C. WALKER. (Univ. Wis.). (*Amer. Jour. Bot.*, 33 (1946), No. 2, pp. 120-129).—The possibility of increasing the ascorbic acid content of cabbage by controlling certain environmental factors and by breeding was investigated. Preliminary sampling and chemical technics resulted in the development of a composite 3 slice method of sampling. A combination of Morell's and of Loeffler and Ponting's technic of extraction and analysis (with some modifications described) was used.

Data obtained (subjected to statistical treatment) led to the following conclusions: "No significant amounts of either dehydroascorbic acid or bound ascorbic acid were found in cabbage heads.

"Significant differences between varieties of cabbage were found to occur independently of fluctuation due to one or another environmental factor. Varieties in the early pointed group were in general higher than those in the early round and midseason round groups. The midseason flat varieties and some of the late flat varieties were the lowest in acid content.

"In a series of transplantings and harvests there was a tendency for heads in the August harvest to be higher than in either July or September harvest.

"In a series of closely related strains there was a highly significant increase in ascorbic acid content in one season over that in the previous season.

"No simple relation was found between ascorbic acid content and temperature, day length, or long-period light energy. The higher ascorbic values in the August harvest, mentioned above, may have been due to low rainfall preceding harvest.

"No correlation was found between stage of head maturity and ascorbic acid content.

"In contrast to previous reports the correlation for the error term which gave the measure of the average relationship between ascorbic acid content and head weight within varieties within a season was not significant.

"No correlation between soil fertility, yield, and ascorbic acid was noted.

"A study was made of inbred lines of Wisconsin All Seasons, a variety which contained 51 to 56 mg./100 gm. ascorbic acid. Lines were derived in which the acid content was not far removed from that of the parent variety, while one line was derived which yielded 80 to 91 mg./100 gm. When individuals from the high

yielding line were crossed with individuals from low yielding lines, the yields in the  $F_1$  progenies were consistently intermediate between the two parents. The possibility of increasing the ascorbic acid content of standard varieties and combining it with disease resistance is discussed."

**The nutritional status of college women as related to their dietary habits:**

**Vitamin stores: Thiamin, ascorbic acid** (*Iowa Sta. Rpt. 1945, pt. 1, pp. 259-260*).—This phase of the study by P. P. Swanson et al. was concerned with the physiological availability of ascorbic acid in cabbage. The preliminary report here presented indicates that the six college women who served as subjects utilized the ascorbic acid in cabbage as well as they did an equivalent amount of the vitamin supplied in the diet in the form of pure crystalline ascorbic acid.

**Effect of processing and storage on the quality and ascorbic acid content of sauerkraut**, C. S. PEDERSON and H. G. BEATTIE. (N. Y. State Expt. Sta.). (*Food Packer, 27 (1946), No. 8, pp. 44, 46, 48, 78, illus. 1*).—Processing studies on sauerkraut revealed that effective pasteurization may be accomplished by filling containers at temperatures just high enough to remove excess  $CO_2$  and to obtain sufficient vacuum in the can, that is, 155° to 165° F.

Various samples of kraut and kraut juice were fortified at different levels with ascorbic acid and stored at temperatures ranging from 32° to 131°. Flavor, color, texture, and ascorbic acid were found stable at 32° and 44.6°. However, as the storage temperature increased, losses in quality and in ascorbic acid increased.

Kraut packed in tin appeared to retain its ascorbic acid better than that packed in glass containers. Ascorbic acid added in tablet form to the container before filling was found more uniform in percentage retention after canning than kraut fortified by adding crystalline ascorbic acid to the preheating tank. Ascorbic acid showed some effect in inhibiting color changes.

**Potatoes** (*Nebraska Sta. Rpt. [1945], pp. 42-43*).—This report presents information on the factors affecting the ascorbic acid content of potatoes. Loss was rapid at a storage temperature of 40° F., but diminished as the temperature increased from 40° to 42.5°, 45°, 47.5°, and 50°. With temperatures of 60°, 75°, and 80°, the loss was possibly a trifle higher than at 50°. Losses in storage were more rapid with the immature potatoes from late plantings than from the more mature tubers. When potatoes with low ascorbic acid content (due to low temperature storage) were moved to room temperature for 6 weeks there was no indication of any increase in content.

Dehydroascrobic acid was found to be present to the extent of 5 to 8 mg./100 gm. of fresh tuber and there was no marked change in the amount throughout the storage period, but by late winter and later the amount was greater than that of the reduced form of ascorbic acid.

Total ascorbic acid content (dehydro plus reduced) of Nebraska potatoes in late winter and spring was found to be from 8 to 12 mg./100 gm. fresh weight.

**The ascorbic acid content of Nebraska-grown potatoes as influenced by variety, environment, maturity, and storage**, H. O. WERNER and R. M. LEVERTON. (Nebr. Expt. Sta.). (*Amer. Potato Jour., 23 (1946), No. 7, pp. 265-267*).—This report is covered in the paper noted above and one noted previously (E. S. R., 95, p. 282).

**Storage conditions which affect the vitamin C content of Maine-grown potatoes**, E. MURPHY. (Maine Expt. Sta.). (*Amer. Potato Jour., 23 (1946), No. 6, pp. 197-218, illus. 3*).—Six varieties of potatoes were held at 32°, 36°, 50°, 60° or 65°, and 70° F. for a period of 7 mo. for two successive seasons. Vitamin C determinations were made at regular monthly intervals during the storage periods. There was an average decrease from 22.7 to 6.3 mg. per 100 gm. during

the 7-mo. period, with one-third to one-half of the total loss occurring during the first month.

The higher temperatures of 50°, 60° or 65°, and 70° were conducive to larger retentions of vitamin C than 32° and 36°, and 60°, 65°, and 70° were not superior to 50°. The tubers remained of good quality at 50° and 36°, and with larger retentions of vitamin C at 50° the indications were that this storage temperature was superior to all others tested. The effect of storage on varietal differences was paralleled by its effect on seasonal variation. New tubers averaged 10.9 mg. higher in 1944 than in 1943; after 7 mo., the average difference was 2.3 mg. per 100 gm.

**Ascorbic acid value of tomatoes canned by five home processing methods** (*Louisiana Sta. Rpt. 1945, pp. 5-6*).—Two varieties of tomatoes, Marglobe and Dixie Gulf State Cross, were utilized in this canning study conducted by M. E. Hollinger and L. Johns. All lots, regardless of the method of processing, were canned in No. 2 tin cans. After scalding, peeling, and coring, each tomato was cut in five vertical sections and these distributed to each of the containers for five methods of processing, which included (1) packing of the cold fruit into the cans, heating to 180° F. by surrounding the cans with boiling water, sealing, and processing for 4 min. at 10 lb. pressure; (2) as above except that processing involved heating for 35 min. in a boiling water bath; (3) heating of the fruit to the boiling point in an aluminum saucepan followed by immediate packing and sealing of the cans and processing for 4 min. at 10 lb. or (4) for 10 min. in a boiling water bath; and (5) boiling the fruit for 20 min. in an open aluminum saucepan followed immediately by pouring into the cans and sealing. After storage for a few days at refrigerator temperature while initial ascorbic acid determinations were made on selected cans taken from the 18 packed by each method, the tomatoes were stored at room temperature pending final ascorbic acid determinations 6 mo. later. Similar vitamin retentions by the first four methods of processing were indicated by the initial and final analyses in which the ascorbic acid values for the several packs varied from 16.6 to 17.2 mg. and from 14.4 to 14.8 mg. per 100 gm. moist basis, respectively. The lot canned by the open kettle method contained 18.3 and 16.0 mg. of ascorbic acid per 100 gm. (moist basis) at the beginning and end of the storage period, respectively. Calculations on the dry basis indicated, however, that these higher values were due to concentration of the nutrients rather than a higher retention, and that actually there was a greater loss of the vitamin due to the longer boiling period. The flavor and appearance of the open kettle processed tomatoes was inferior to those processed by the other four methods. Cold packing resulted in larger head space than hot packing.

**Home canned tomatoes** (*Nebraska Sta. Rpt. [1945], p. 42*).—In tests with tomato home-canning methods, ascorbic acid losses from the fresh fruit to the processed tomatoes were significant. The decrease occurred as a result of blanching, processing, and storage, with the latter accounting for the largest total loss. Recommendations for minimum loss include short blanching periods and storing the product in quarts instead of pints. "In the open-kettle method at least 10 percent more evaporation of moisture takes place than in the hot- or cold-pack methods. Therefore, a 100-gm. serving of tomatoes canned by the open-kettle method will contain a greater original weight of fruit and will furnish more ascorbic acid than a 100-gm. serving of fruit of the same initial value but canned by other methods."

**The effect of ripening, storage, and other methods of handling on vitamin C in apples.** (*Iowa Sta. Rpt. 1945, pt. 1, pp. 263-264*).—This study by P. Swanson, H. H. Plagge, et al., here noted as a report of progress, indicates

that a method of sampling was worked out to give a picture representative of apples from the orchard as a whole. "A statistical analysis of the variation in the ascorbic acid content of lots composed of 20 apples made up of 5 apples from each quadrant of the orchard showed that, while apples picked from different quadrants in the orchard varied statistically in ascorbic acid content, the variation between means of lots composed of 5 apples from each quadrant was not statistically different." Of the 10 varieties of apples tested, all but 1 averaged about 5 mg. percent of ascorbic acid; the Willow Twig variety, however, contained about 25 mg. percent of this vitamin, which was retained very well through 7 mo. of storage at 32° F.

**Varietal differences in the ascorbic acid value of strawberries** (*Louisiana Sta. Rpt. 1945, pp. 6-7*).—In this study by M. E. Hollinger, standard and seedling varieties of strawberries produced in breeding trials were analyzed early, mid-way, and late in the bearing period in the seasons 1942, 1943, and 1944. Analytical data reported on the samples showed that during the 1942 and 1943 seasons, ascorbic acid values were highest in most cases early and late in the season. In 1944, however, the highest values were obtained at the midseason sampling. Although ascorbic acid values for each variety varied considerably, those varieties having the highest values remained consistently in the higher ranks while those having lowest values remained consistently in lower ranks. The Fairmore variety had, in most instances, the highest ascorbic acid value of all varieties tested, averaging 77 mg. per 100 gm., but a cross between two Blakemore-Klondike seedlings designated as 117-1 gave average results only slightly lower. The Klondike and Kloumore varieties ranked rather consistently low, while the Konvoy variety was more variable. Average results of all determinations on these varieties were for Konvoy 62 and Klondike 58 mg. per 100 gm.

## TEXTILES AND CLOTHING

**The action of antiperspirant creams on fabrics**, R. R. BIEN (*Toilet Goods Assoc., Sci. Sect. Proc., 1945, No. 4, pp. 8-12; also in Amer. Dyestuff Rptr., 35 (1946), No. 11, pp. 269-271, 290-291*).—A laboratory method is described for determining possible fabric destruction by cream type antiperspirants. After test application, the tensile strength of the treated material is determined against controls. A decrease of tensile strength, under the conditions of this test, indicates that up to 20 percent is allowable provided that the number of breaks showing a reduction in tensile strength over 20 percent does not exceed 5 out of a total of 25 tested.

The author concludes: "This investigation will have to be extended to a much larger group of products before any definite conclusion can be reached.

. . . The importance of every single ingredient in an antiperspirant cream formula may not be fully appreciated. The composition of the base material is fully as important as the proper balance of aluminum salt and buffer. To change any single ingredient, or its concentration, in a satisfactory formula, is to risk increasing the fabric destruction potential from a safe to a dangerous level."

**Mildew and rot resistance of textile and effectiveness of textile fungicides: Tentative method (3rd revision—April 4, 1946)** (*Amer. Dyestuff Rptr., 35 (1946), No. 11, pp. 274-276*).—Tentative methods are described for (1) determining the behavior of textiles with respect to mildew, and (2) evaluating the mildew preventives offered to the textile trade. Descriptions are given for the actual test procedures with their applications and interpretations in testing both the initial resistance of textiles and permanence of such resistance. The application of these tests in determining the fungicidal potency of mildew pre-

ventive compounds under uniform conditions and in determining their permanence when applied to a standard fabric are also described.

**Dimethylglyoxime-copper treatment for rotproofing fabrics**, A. C. NEISH, G. A. LEDINGHAM, and A. G. MACKEY (*Canad. Jour. Res.*, 23 (1945), No. 3, Sect. F, pp. 198-201, illus. 1).—"Copper was fixed in jute, coarse cotton, and woolen fabrics by dipping the test materials for 2 to 5 min. in a 0.5 percent aqueous solution of dimethylglyoxime at 90° to 100° C., and then immersing them in 5 percent copper acetate at room temperature for 5 min. The amount of fixed copper was varied by altering the strength of the copper solution. The treated fabrics were odorless, remained pliable, and were dyed a khaki color. As determined by soil burial tests, this treatment proved more effective than that with copper naphthenate for rotproofing purposes."

**The soil burial test for rot-proofed cotton fabrics**, J. D. DEAN, W. B. STRICKLAND and W. N. BERNARD. (U. S. D. A.) (*Amer. Dyestuff Rptr.*, 34 (1945), No. 10, pp. 195-201, illus. 6).—As a means of determining the effectiveness of proofing treatments on fabrics exposed to soil burial after different intervals of exposure, protected and unprotected samples were subjected to breaking strength tests to measure their resistance to the cellulose-destroying activity of the soil. The tests described were made with triplicate burials of six specimens each, and although the average results were not considered absolute values, they were regarded as representative of the effect of soil temperatures and moisture. Other environmental factors which influenced the rate and extent of the rotting included the composition of the soil used and method of burying the sample; pH was not considered extensively as neutral soils were used throughout the tests. Copper naphthenate was used as a standard control proofing treatment against other commercial compounds. The results of the individual tests, expressed as resistance numbers which were derived from rot-resistance quality of the fabrics in view of their strength loss and length of burial, ranged from 36 to 46 days, averaging 42 days. It is considered that a resistance number of 42 days represents a norm of control-fabric rotting under standard testing conditions. Under these conditions, a well protected cotton fabric weighing 6 to 8 oz. per square yard normally required 3 weeks' burial in fresh soil before significant deterioration occurred. Lighter fabrics were more rapidly attacked, and less effective treatments may be detected after a week or two of soil contact. Several of the copper compounds employed in the rot proofing of the cotton textiles were found responsive to the influences that produced accelerated rotting.

**Mould growth on leather**, A. J. MUSGRAVE (*Chem. and Indus. [weekly]*, No. 24 (1946), pp. 226-227).—The author reviews (19 references) the mycological problems of the leather industry and the prevention of mold growth by alterations in processes of handling and manufacture and by use of poisons or fungicides.

## REPORTS AND PROCEEDINGS

**Annual report of the director [of Delaware Station], 1945**, G. L. SCHUSTER (*Delaware Sta. Bul.* 259 (1945), pp. 43).—Brief reports are made of progress results in agronomy, including tests of improved strains of grasses, varieties of wheat, soybeans, barley, and oats, pasture management, corn hybrids, fertilizer placement for soybeans and corn, and minor elements for corn; animal husbandry, including work with improved strains of poultry, dehydrated vegetable wastes in poultry feeds, hatchability of eggs, effect of moisture on sporulation of coccidia, value of sulfonamides and other treatments in coccidiosis and fowl typhoid control, transmission of fowl typhoid by turkey buzzards and flies, viability of

fowl typhoid organisms, rations for finishing broilers, litter management, and roughage consumption in dairy cows; chemistry, including factors inducing jellying of pectin, and ascorbic acid losses in frosted kale; entomology, including mosquito observations, control of bean and cucumber insects, ethylene dichloride emulsion for control of peach-tree borer, control of Japanese beetles and European corn borers, and miscellaneous insect notes; horticulture, including fertilizer and variety tests with potatoes, including resistance to leafhoppers, certified v. home-grown potato seed, and whole v. cut potatoes, fertilizer, cultural, breeding, and variety tests with tomatoes, fertilizer v. variety tests with cantaloups, variety tests with sweet corn, sweetpotatoes, cucumbers, and watermelons, hormone sprays for lima beans and tomatoes, fertilizers for lima beans, poultry manure for strawberries, injury to apples by methyl bromide fumigation, and thinning apples and peaches with Elgetol; plant pathology, including chemical control of wilt in sweetpotato sprouts, production of strawberries resistant to red stele, factors influencing leaf blights of corn, control of diseases of soybeans, lima beans, and extensive studies of new fungicides and synthetic organic chemicals.

**Annual Report [of Florida Station], 1945, H. Mowbr.** (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1945, pp. 229+, illus. 22*).—In addition to items noted elsewhere in this issue, brief progress reports are given on the various projects of the station, substations, and field laboratories. Among the many projects for which data are reported are those in agronomy, including studies on peanut, oat, tobacco, and corn improvement, crop rotations, variety tests with millet, Sudan grass, oats, sugarcane, Bermuda grass, cotton, and cowpeas, pasture fertilizers, crop varieties, and grazing tests, effect of burning on range plants, pasture legumes, effect of environment on composition of forage crops, fertilizer, cultural, and variety tests with tobacco, fertilizer and cultural tests with peanuts, and sulfur dusting of peanuts and cotton; animal industry, including ensilability of urea and sorghum and of grapefruit pulp, cause of infectious bovine mastitis, inversion of sucrose for ice cream making, effect of citrus press cake silage on milk flavor, condensed buttermilk and peanut meal in laying rations, beef production on carpet grass, periodic v. continuous lighting for egg production, sulfurization of soil to control poultry parasites, composition of Florida waters, use of DDT to control horn flies, toxic principle of the tung tree and tung meal, cause and treatment of "swollen joints" in range calves, dehydrated celery tops, tung meal, and grazing crops for poultry, and effect of diethylstilbestrol on milk production; entomology, including control of nut and leaf casebearers of pecans, cutworms and armyworms, nematode control by resistant seed strains, mulches, and soil fumigants, cane sirup and honey for baits on thrips, and tests of DDT for control of Colorado potato beetle, melon and pickle worms, chinch bug, and other insects; home economics, including vitamin activity of various foods, especially Florida fruits and vegetables, chemical composition and properties of royal jelly, and relation of the school lunch to health and progress; horticulture, including culture of tung trees, values of manganese for crepe myrtle, cover crops and potash for pecans, minor elements for peas and grapes, the splitting of Bermuda onions, cold storage of citrus fruits to check diseases, freezing of citrus juices and hearts, effect of soil reaction on broccoli and peppers, fumigation of narcissus bulbs, minor elements for cabbage, cultural requirements of the mu oil tree and hybrids, zinc, magnesium, potash, boron, naphthaleneacetic acid, and naphthaleneacetamide for pecans and zinc-bordeaux v. zinc-manganese-bordeaux as sprays, pliofilm and other wrappers and packages for tomatoes, carrots, and other vegetables, variety tests of beans, sweet corn, onions, and lettuce, composition of Florida-grown cabbage, carrots, and other vegetables as affected by environment, irrigation of sweet corn, and freezing of Florida vegetables; plant pathology,

including host relations and factors influencing the growth, parasitism, and control of *Sclerotium rolfsii*, seed and soil treatments with cowpeas, lettuce, spinach, tomatoes, beans, lima beans, and squash, studies of phomopsis blight and fruit rot of eggplant, azalea flower pot, rhizoctonia damage to lima beans, snap beans, and cabbage, camellia dieback, witches'-broom of oleanders, dusts for cucumbers and lupines, and pythium root rot of Easter lily; soils, including studies of microbial action in fine sand soils, soil analyses, factors affecting the growth of legume bacteria and nodule development, role of maintenance of soil reaction and organic matter and significance of levels of readily soluble major nutrient elements, correlation of soil characteristics and pasture crop response, fertilizer tests for cabbage, and availability of various phosphates; celery investigations, including soil and fertilizer studies, variety tests with potatoes and sweet corn, and cover crops; potato investigations, including disease control, variety tests with potatoes and cabbage, downy mildew of cabbage, and potato and cabbage culture and fertilizer tests; watermelons and grapes, including fusarium wilt and other fungus diseases of watermelons and fruit rots of grapes; vegetable crops, including prevention of seedling injury in tomatoes, variety tests of tomatoes, onions, corn, and beans, breeding for resistance to tomato diseases and insects and to downy mildew in cucumbers, control of lepidopterous larvae on corn, factors influencing manganese and iron deficiencies, cover crops, lime, and sulfur for vegetable crops, control of mole crickets, value of DDT for control of cabbage insects, leafhoppers on peas, pepper weevil, bean leaf roller, and tomato and potato insects, rapid soil fertility tests, organic fungicides for foliage diseases of tomatoes and cucumbers, gladiolus culture, salinity and fertility levels in soils, and ammonium sulfamate and 2,4-D as herbicides; range cattle, including studies of wintering beef cattle, improving flatwoods pastures with fertilizer and minor elements, and weight changes and mineral consumption by range cattle; at the Subtropical Station, cultural studies with Tahiti limes, avocados, mahogany and balsa seedlings, papayas, mangoes, annonas, ginger, pineapples, and other fruits, leaf spot of papaya and fruit spot of white sapote, potato and tomato culture and fertilizers, cover crops, control of potato late blight and ring rot, cercospora spot and fruit rot of avocados, mango anthracnose, and tomato blight and root necrosis, variety tests of cantaloups, cauliflower, sweet corn, cucumbers, onions, rice, strawberries, and carrots, dasheen culture, diseases and nitrate requirements of Tahiti limes, salt content of wells and soils, high nitrate content in Perrine marl, waxing of tomatoes and potatoes, and sclerotinose disease of beans and varietal resistance to it; at the Citrus Station, storm losses to citrus fruit, studies of melanose and stem-end rot, citrus nutrition and fertilizers, timing of oil sprays, control of scale insects and mites, so-called "spreading decline," addition of color to fruits, control of stem-end rot and mold fungi with thiourea and 8-hydroxyquinoline sulfate, oil sprays for citrus, soil moisture studies, and fertilizer tests; at the Everglades Station, meteorological data, studies of soil and water conservation, machinery for decorticating *Sansevieria* fiber, an improved mowing machine, value of superphosphate for oranges, and copper sulfate for corn on new sawgrass peat, control by DDT and other insecticides of bean leafhopper, bean leaf roller, cabbageworm, potato insects, corn earworm, mole cricket, American cockroach, horn fly, stablefly, onion thrips, weevils, and insects in hospitals, soils tests and treatments, fertility studies with potatoes and celery, water control, weed killers, mineral requirements of cattle, response to sulfur of celery and lettuce and to manganese of potatoes, control of sugarcane moth borer, sugarcane breeding, beef production in the Everglades, pasture improvement, cultural studies with sugarcane, barley, and other cereals and grasses, corn, soybeans, *Sansevieria*, ramie, and sirup and forage canes, seed treatment

of potatoes, fungicides for beans, control of leaf blights of potatoes, peas, beans, and tomatoes, analyses of celery and carrot leaves and stems and broccoli and collard leaves as potential sources of dehydrated feeds, control of brown root rot, virus diseases and early blights of celery, cutworms and armyworms, variety tests with snap beans, lima beans, cabbage, sweet corn, potatoes, and tomatoes, and value of shallu, blackstrap molasses, and sweetpotatoes for steers on winter pasture; at the North Florida Station, meteorological data, studies of disease-resistant varieties of tobacco, cover crops for pecan orchards, germination and early growth of tobacco seedlings, performance of Columbia sheep, breeding corn, oats, barley, wheat, velvetbeans, and sorghum, value of kudzu as a grazing and hay crop, control of downy mildew of tobacco, ground oats for fattening steers, tobacco rotations, swine-feeding tests, methods of seeding lupines, varieties and strains of peanuts, sweetpotatoes, cotton, lespedeza, potatoes, corn, cotton, and oats, and fertilizer tests with corn, cotton, peanuts, pastures, and lupines; and at the West Central Station, grazing tests with cogon and Bahia grasses.

**Report on agricultural research [of Iowa Station] for the year ending June 30, 1945, I, II, R. E. BUCHANAN *et al.*** (Partly coop. U. S. D. A.). (*Iowa Sta. Rpt. 1945, pts. 1, pp. 355, illus. 68; 2, pp. 91, illus. 18*).—In addition to several items abstracted elsewhere in this issue, part 1 contains special reports on Apple Breeding at the Iowa Station, by B. S. Pickett (pp. 21–26); and Oat Improvement at the Iowa Station Through a 40-Year Period, by H. D. Hughes (pp. 27–46). There are also the customary reports on projects as carried on in the section of agricultural engineering, including farm building losses due to wind and fire, atmospheric exposure tests of wire and fencing, utilization of cornstalks for building insulation and of steel in farm building construction, methods of harvesting and storing hay, storage and distribution of manure, growing row crops and maintaining a surface mulch of crop residues, milling of hemp, adapting farm buildings to meet changes in farm operations, development of machines for peat land and terrace construction, and curing hay in the mow by mechanical ventilation; agronomy, including studies of technics in seed analysis, varietal response to cultural methods with oats and wheat, comparison of sweetclover species, varieties, and strains, variety tests of soybeans, barley, and flax, improvement of brome grass, oats, barley, wheat, soybeans, orchard grass, birdsfoot trefoil, grasses and legumes for soil conservation, hemp culture and improvement, adaptation of soybeans to local conditions, pasture improvement and management, development of lespedeza, clovers, alfalfa, and Kentucky bluegrass, carotenoid content of orchard grass, effect of hail damage on soybeans, soil microstructure in relation to soil tilth, availability of phosphorus and potassium in soils, fertilizer response on different soil types with corn, oats, and alfalfa, characteristics of Iowa soil types, influence on soils of mineralogical nature of clays and aggregates, effect of cultural practices on soil moisture, crop rotations for hardpan soils and silt loam, sweetclover in short rotations, soybean production in relation to fertilizers, effect of cover crops, contouring, crop residues, and cropping systems on soil and water conservation and crop yield, nitrogen fixation by soybeans, the retting of hemp, management of peats, sands, and other soils for truck crop production, wartime needs for agricultural lime, evaluation of drainage installations, liming and fertilizer for slowly drained lands, methods for spectrochemical analysis of soils and plant materials, and relation of the soil profile to level terraces; animal husbandry, including studies of inbreeding in Holstein-Friesian cattle, Poland-China hogs, and other pure breeds, value of the Danish Landrace breed for swine improvement, production of sterols and their role in nutrition, relation of vitamin E to sheep and poultry, evaluation of swine breeding stock, growth measurements of colts, brucellosis in swine, systems of

feeding lambs, soybeans and soybean products for milk production, physiology of digestion in fore stomachs of calves, preservative effect of carbon dioxide on meats in storage, inbreeding and crossing in fowls, effect of ration and fattening period on poultry, association of so-called nonspecific enteritis of chickens with fowl leucosis, mode of inheritance of resistance and transmission of the iritis type, storage changes in dried egg albumen, post mortem changes in the poultry carcass, wheat germ oil as a supplement to poultry rations, microbiology of frozen eggs, factors affecting functional properties of reconstituted dried eggs, and use of baled straw for temporary poultry houses; bacteriology, including the function of carbon dioxide in bacterial metabolism, conditions for optimal yield of 2,3 butylene glycol, mechanism of vitamin action in micro-organisms, and fermentation production of nitrogenous yeast feeds from corn mash; botany and plant pathology, including breeding for disease resistance in melons, parasitism of the rusts, smuts, and other diseases of oats, propagation of disease-free sweet-potato seed stock, pink root and neck rot diseases of onions, plant ecology in waterfowl breeding areas of Iowa, influence of chloropicrin seed treatment on stands and yield of peas, flax, oats, barley, and wheat, effect of seed treatment on strains of sugar beets, hill culture crops and methods (especially sumac for tannin), control of potato late blight, scab, and other diseases, black stem rust (by barberry eradication), tests of *Asclepias* sp. and other rubber-producing plants, control of the oak wilt fungus, diseases of barley, soybeans, and brome-grass, and fungi as sources of protein supplements for feeding; chemistry, including studies of antibiotic peptids and inhibition by amino acids on dextrose to check deterioration of dried eggs; dairy industry, including studies of dairy bacteria, the acids in butter, the mechanism of formation of acetylmethylcarbinol, the ripening of cheese, and the vitamin A and beta-carotene contents of Iowa butter; economics and sociology, including the existence and significance of specific agricultural cycles, analysis of farm records, economic use of farm credit resources, adjusting transportation to wartime needs in livestock marketing, land market controls, wartime shifts in farm organizations and management problems concerned with dry milk solids production in Iowa, agricultural price control after the war, programs to expand domestic consumption, improvement of Iowa farm leasing agreements, place and grade differentials in hog prices, and neighborhood and community extension technic as a means to maximize agricultural production; entomology and economic zoology, including the influence of meteorological factors on honey production, insecticides and insect toxicology, control of potato insects with DDT and other insecticides, screwworm infestation, DDT for control of cucurbit insects and codling moths, factors involved in honey production from nectar, management of quail, ducks, and pheasants, ecology of the muskrat, resistance of honeybees to American foulbrood, cottontail rabbit production, and control of nonmigratory grasshoppers and sweetclover weevils; foods and nutrition, including studies of the leavening power of dried whole milk and the defrosting and cooking of frozen beef; forestry, including the control of white pine blister rust, survival of tree seedlings under grass competition, and the amounts and grades of lumber from white elm, cottonwood, and red oak; genetics, including studies of breeding for resistance to fowl typhoid and typhoidlike diseases, genetics of virulence in the mouse typhoid organism, radiation effects on genes, bacteria, and viruses, polyploidy in tomatoes, and heterosis in *Drosophila*; horticulture, including studies of the maintenance of fine turf grasses, tests of garden annuals and herbaceous perennials for heat resistance and adaptability to cut flower production, responses of greenhouse plants to Iowa soil types and soilless culture, propagation of apple stocks, soil management for apple orchards, breeding of apples, pears, plums, and peaches, hybridization of black raspberries for

immunity to anthracnose, influence of stock on scion in apple production, breeding rose stocks, freezing fruits and vegetables in refrigerated locker storages, responses of fruit to treatments before and during storage, placement of apple trees with soil erosion terraces, controlled dehydration in the home, and effect of ripening, handling, and storage on thiamine and riboflavin content of apples, potato and onion breeding, shrinkage of sweetpotatoes in storage, fertilizers for sweetpotatoes and cantaloups, varieties of snap beans, sweetpotatoes, and cantaloup, vegetable production on muck and peat soils, and optimum storage conditions in the household refrigerator for frozen soybeans, corn, and peaches; statistical methods, including studies of methods for yield determination in experimental plats, examination of climatological data, a national sample of farms, use of lattice designs, the A. O. A. C. chick method of assay for vitamin A, and relative pounds of ear corn and shelled corn; textiles and clothing, including studies of the protection from degradation by certain finishes on cotton cellulose, regenerated cellulose, and cellulose-acetate rayon, and uses of hemp in textile fabrics, vocational education, including an evaluation of the Iowa State College curriculum in agriculture; studies of farm tenancy; and observations on plantings of *Trifolium ambiguum*, creeping alfalfa, longevity of red clover seed, and spreading habits of wild carrot.

Part 2 is the tenth annual report of the Iowa Corn Research Institute. Following an article entitled Popcorn Breeding in Iowa, by J. C. Eldredge and I. J. Johnson (pp. 7-16), reports are given on soils and soil management, including comparative value of different phosphate fertilizers; rotation and fertilizer studies, and chemical tests for determining fertilizer needs; cultural methods and equipment, including those for storage and curing corn and silage, weed control, tests of hybrids, and influence of pathological factors on seed germination; corn breeding, including the genetic transfer of starch characteristics, development of pure inbred lines, sweet corn and popcorn breeding, and hybrid production; botany, including physiological studies of hybrids, crosses, and inbreds, synthesis and translocation in the corn plant, and interactions of water, growth hormones, and food supplies; pathology and mycology, including resistance to *Ustilago zeae*, measuring disease resistance in corn and related species, and methods of combating diseases of corn, oats, and potatoes; insects, including the chinch bug and European corn borer and their control; chemistry and composition of corn, including methods of analysis, studies of starch, protein, and vitamins; industrial utilization, including technics for cornstarch production; corn and corn products in human and animal nutrition, including tests of corn and corn silage in full v. limited grain feeding, and nutritive value of shelled corn as affected by storage.

Fifty-eighth annual report [of Kentucky Station], 1945, T. P. COOPER (*Kentucky Sta. Rpt. 1945, pp. 68*).—In addition to items abstracted on pages 894 and 895 of this issue, this report notes briefly progress on the following: Farm land values in Kentucky, capital investments and income in farming, farm management on grass farms, prices in Kentucky and the United States, distillers' wheat dried solubles as a protein supplement and bluegrass-molasses silage v. alfalfa-molasses silage for fattening steers in dry lot, digestibility of distillers' corn dried solubles, alfalfa, bluegrass, and corn silages and barn-cured v. field-cured alfalfa for pregnant and lactating ewes, continuous v. rotational grazing, pastures for finishing, and grain rations for lambs, yearling weight and performance of western ewes, survival of nematode parasites of sheep on pasture, distillers' wheat and corn dried solubles for pigs, alternate v. continuous grazing of bluegrass pastures by dairy heifers, bacterial extract vaccine for mastitis, distiller's wheat dried solubles as a protein supplement for dairy cows, effect of age of hens on eggs, vegetable protein for laying pullets, crooked keel bones, osteopetrosis, and an un-

identified osteoma in chickens, control of poultry lice with DDT, analyses of cases of equine abortion and infection of newborn foals, and histopathology of non-infectious diseases, in coordination of horses (wobblers), penicillin for horses, occurrence of *Salmonella* and paracolon bacteria, arsenic, boron, and manganese in animal nutrition, corn hybrids and improvement, hybrid popcorn, corn borer life history and parasites, hardiness in winter oats, variety tests of oats, barley, wheat, rye, red clover, and lespedeza, production of hay and Kentucky bluegrass seed, control of plant bugs, wireworms, and green June beetles, fertilizers for pastures, corn, tobacco, and orchard grass, use of a barn hay drier, effect of crop residues on soil nitrates, methods of fertilizer application for wheat, corn, and tobacco, tests of the Neubauer culture method for soil P and K, mechanical fractionation of soils, tobacco diseases including *Fusarium* wilt, streak, frog-eye, root rots, and mosaic, overwintering of *Salmonella typhimurium*, priming and curing Burley tobacco, nutritional value of tobacco seed, production of nicotine from green tobacco and nicotinic acid by nicotine oxidation, variety tests of lima beans, tomatoes, and sweet corn, control of codling moth, plum curculio, apple scab, phloem necrosis, oriental fruit moth, Japanese beetles, and May beetles, peach pruning systems, strawberry mulching, pasture experiments, distillers' wheat dried solubles v. soybean oil meal for steers, vegetable v. animal protein for pullets, rate of phosphate applications, top dressings for alfalfa, grass variety tests, apple cover crops, variety tests of apples, peaches, plums, blackberries, and strawberries, and production of sorghum sirup and mine props.

**Research in Agriculture: Annual Report [of the Louisiana Station, 1945]**

W. G. TAGGART ET AL. (Partly coop. U. S. D. A.). (*Louisiana Sta. Rpt. 1945*, pp. 144, illus. 2).—In addition to findings on the ascorbic acid content of tomatoes and strawberries noted on pages 898 and 899, this report presents data on nutrition research, including the carotene content of sweetpotatoes, the vitamin A content of milk and butter, nature of the lipoid microbiological growth stimulants found in rice polish, experimental lathyrism from Singletary peas, detoxification of tung meal, and toxicity of the tung nut; food preservation, including studies of freezing strawberries, frozen shrimp and its packaging, loss of added vitamin C in storing frozen peaches, use of frozen potatoes for French fries, and tests of strawberry and peach varieties for freezing; agricultural economics, including economic aspects of peach production in Louisiana, the mechanization of cotton production in upland areas, tractors on upland farms in north Louisiana and cost of operating tractors and other mechanical equipment in Delta areas of Louisiana, farm management and cost studies with sugarcane, milk, and sweetpotatoes, wartime production capacity on Louisiana farms, cottonseed and cotton marketing, and prices and statistics; agricultural engineering, including studies of electric hotbeds, mechanical diggers, and dehydrators for sweetpotatoes, flame cultivators, effect of cover crops and deep plowing on crop yields and soil loss, rice storage in steel bins, and mole drainage of sugarcane land; animal industry, including swine breeding, management of beef cattle pastures, and winter grazing, soybean meal and peanut meal for pigs, and fertilizing pastures on old rice land; crops and soils, including a 12-mo. grazing program, effect of fertilizer on cotton fiber quality, Dallis grass improvement and seed production, effect of depth of application of nitrogen on the rice crop, sugarcane fertilizer, crop rotation, fertilizer practices, including tests with oats, corn, and cotton, and corn varieties and hybrids; dairy research, including mineral deficiencies of Louisiana herds, inherited tolerance to heat, night grazing in hot weather, effect of high humidity and temperature, pasture improvement with manure and fertilizer, and value of early-cut hay for dairy cattle; entomology, including the use of DDT-nicotine dust on cabbage, control of the sand wireworm,

velvetbean caterpillar on soybeans, cotton boll weevil, cotton aphid, sugarcane borer, turnip aphid, onion thrips, and tomato fruitworm and early blight, and tests with DDT against American and German cockroaches, fleas, the brown dog tick, and flies; home economics, including studies of food habits and dental conditions; horticultural research, including sweetpotato breeding, industrial use, carotene content, and waxing in storage, breeding potatoes, strawberries, pole and lima beans, and gladiolus; plant pathology, including hot-water treatment for sugarcane, control of nematodes by soil treatment and of mildew and anthracnose of cucumber by Fermate, control of black scale disease of lily bulbs, weed control with 2, 4-D, control of Blakemore yellows of strawberry and blight of arborvitae, rice disease studies (use of fertilizer in root rot and white tip and fungicides for rice seeds), a new race of *Cercospora oryzae* on Rexoro rice, control of soil rot and black rot of sweetpotatoes, vegetable seed treatments, soil treatment for shallot white rot, and losses from mildew on shallots and onions; poultry research, including importance of green feed, farm egg coolers and frequent marketing, improvement by breeding, and coccidiosis control; rural sociology, including medical personnel, facilities, and services in Louisiana, the educational status of Louisiana's farm population, and population composition and changes; sugarcane, including tests of varieties; veterinary science, including studies of John's disease, anaplasmosis, gastrointestinal nematode parasites in cattle, *Crotalaria spectabilis* poisoning of livestock, and "pinkeye" treatment in cattle; and at the substations, strawberry varieties and use of lime and fertilizers, pepper and okra breeding, corn varieties, fertilizers, and spacing, varieties and spacing of sorghum, cotton varieties and fertilizers, varieties of Sudan grass and tomatoes, sweetpotato fertilizers and varieties, peach fertilizers, hogging off corn, green feed for hens, turkey production in north Louisiana, rice fertilizers, rotations, varieties, and use of calcium arsenate, substitutes for rotenone and pyrethrum on cole crops, sweetpotato weevil studies, bee culture, potato breeding, corn hybrids, cotton diseases (especially fusarium wilt) and varieties, and varietal resistance to sweetpotato diseases.

**Fifty-ninth Annual Report [of Nebraska Station, 1945], W. W. BURE.** (Partly coop. U. S. D. A.). (*Nebraska Sta. Rpt.*, [1945], pp. 119, illus. 23).—In addition to findings noted elsewhere in this issue, this report presents results in soils research, including erosion control and moisture conservation, crop residue management, fertilizers for corn, wheat, barley, bromegrass and other grasses and alfalfa, nitrate production in soils after grasses, infiltration of irrigation water, and alkali in soils; field crops, including rotations, variety tests of wheat, barley, oats, sorghum, and corn (hybrids), pollination of grasses and seed production, time of cutting prairie hay, improvement of birdsfoot trefoil, milk vetch, crown vetch, Korean lespedeza, sweetclover, alfalfa, soybeans, safflower, castorbeans, and sesame, seed production in sweetclover, and 2,4-D for control of bindweed, hoary cress, Russian knapweed, Canada thistle, whiteweed, tanweed, and other weeds; horticultural crops, including storages for seed potatoes, potato culture, breeding, ascorbic acid content, heat resistance, and cracking, ascorbic acid content of tomatoes, tomato breeding, variety tests with sweetpotatoes, lima beans, walnuts, and apple stocks, rotations, supplemental water for orchards, and orchard spraying; plant diseases, including tests of sprays for control of halo blight in beans, seed treatments of oats, wheat, sorghum, and barley, resistance to leaf rust of wheat, charcoal rot of corn and sorghum, mold in stored corn, cornstalk rots, phloem necrosis of elms, pine twig blight, seed piece rot, pink rot, blackleg, late blight, scab, and an unidentified disease of potatoes, blight, leaf spot, bacterial speck of tomatoes, and bacterial spot of peppers; chemistry, including studies of amylases and their inhibitors and the protein-digestion in-

hibitor in raw soybeans; insects, including tuber flea beetles and aphids on potatoes, use of airplanes for applying dusts and sprays, field tests of DDT and other materials, control of chinch bugs, hessian fly, grasshoppers, corn rootworms, corn borers, onion thrips, and pine tip moth, DDT for fly and bedbug control, control of chicken mites, and greenhouse pests; animal husbandry, including tests of distillers' solubles and substitutes for alfalfa meal for pigs in dry lot and their protein requirements, relation of sorghums to lithiasis, anascara, and pathological liver condition in cattle, distillers' dried grains and solubles and safflower meal for wintering steer calves and fattening steers, use of pasture for finishing cattle, and progeny testing of rams; dairy husbandry, including studies of factors affecting reproduction, artificial insemination, protein supplements in a calf starter, carotene content of Nebraska grasses, cheese making, vitamins in cheese and butter, and ice cream stabilizers; poultry husbandry, including studies of the marketing point for turkeys, estrogens for fattening cockerels, protein utilization by chicks and poults, and vitamin D irradiation of chicks; animal diseases, including studies of swine erysipelas and mortality in turkey flocks; agricultural engineering, including work on heating drinking water for livestock, weed control, improvements in farm refrigeration and freezers, thermostats for potato storage, emergency methods of cooling milk and cream, machinery for seedbed preparation for corn, and corn drying methods; rural economics, including studies of cost of producing crops, farm organization, land use planning, land tenure, and farm credit; home economics, including studies of blood regeneration by donors and farm lighting; and at the substations, studies of supplements to prairie hay for wintering calves, potato breeding, crop rotations, lamb feeding tests and origin of lambs as related to urinary calculi, variety tests of wheat, oats, barley, corn, and sorghum, weed control with 2,4-D, range cattle feeding, and pump irrigation.

**Fifty-eighth Annual Report [of Cornell Station], 1945, W. I. MYERS ET AL.** (Partly coop. U. S. D. A.). ([*New York*] *Cornell Sta. Rpt. 1945*, pp. 81-169).—In addition to work noted elsewhere in this issue, this section of the report deals with the progress of investigations in agricultural economics, including an analysis of methods and practices involved in the distribution of apples and competitive fruits in New York City by chain and independent retailers, the elasticity of the demand for corn and oats, costs of milk processing and distribution, and farm-labor simplification; agricultural engineering, including exposure tests of fence wires and paints; agronomy, including the properties of New York peat and muck deposits, relation between physicochemical properties of New York soils and their response to fertilization, potash requirements of leguminous forage crops, studies of birdsfoot trefoil, methods of improving feed crops in New York State, and plant associations for permanent pastures; animal husbandry, including the technic of artificial insemination, effect of curing methods on feeding value of hay, nutritive value of timothy hay at three stages of maturity, carotene and vitamin A requirements of the dairy calf, nutritional requirements of herbivora, protein levels and supplements for lambs, cause of stiff-lamb disease, and methods for fattening calves; botany, including weed control with borax, plant sources of rubber, and germination of vanilla seed and hybrids; dairy industry, including the nicotinic acid, pantothenic acid, and biotin content of milk, survival of *Bacillus abortus* in cheese, keeping quality of pasteurized milk, studies of disinfectants and antiseptics, methods for determining chlorides in milk, ascorbic acid oxidation of milk fat, deaeration of milk, endospore formation in *B. mycoides*, the cytoplasmic membrane of the bacterial cell, nutrition and varieties of streptococcal bacteria, and subacute endocarditis; entomology and limnology, including the control of lettuce yellows

through control of the aster leafhopper, studies of the onion thrips, squash bug, flea beetle on tomato transplants, alfalfa snout beetle, white grubs, European chafer, and seed-corn maggot, control of sheep ticks and flies with DDT, control of potato insects, studies of the small-mouth bass, insecticidal constituents of the yam bean, selenates for pest control on florist crops, and fumigants for red spider mite in greenhouses; floriculture and ornamental horticulture, including the correlation of quick tests with rose growth in the greenhouse, soil mixtures for roses, snapdragon and leaf scorch, effect of cutting time on the keeping of roses, pruning *Spiraea vanhouttei*, and seed dormancy in cabbage; plant breeding, including genetic studies with barley, oats, and wheat, breeding wheat, oats, barley, corn for silage and grain, cabbage, soybeans for grain and food, celery, zigzag clover, red clover, other forage legumes and grasses, beans, cucumbers, melons, and potatoes; plant pathology, including studies of the X-virus of potatoes, development of immune or disease-resistant stocks, potato scab, rugose mosaic, leaf roll, and golden nematode disease of potatoes, control of celery blights, onion smut, gray mold and drop of lettuce, spraying and dusting of fruit trees, soil fumigants, and fungicides for apple scab; pomology, including influence of soil type on fruit plants, control of preharvest drop of apples, influence of blossom sprays and thinning on annual bearing of apples, thinning peaches by sprays, and storage studies on apples; poultry husbandry, including genetic resistance to avian leucosis, poultry requirements for the vitamin B complex, and value of choline, milk byproducts, and dehydrated grasses for poultry; rural sociology, including social participation of rural families, types of families residing on marginal and submarginal land, the rural community in wartime, and attitudes of farm women toward rural cooperative organizations; vegetable crops, including soil reaction studies for potatoes, vegetable crops for muck and irrigated soils, lettuce improvement, fertilizer studies with potatoes, potato storage on Long Island, rapid methods for diagnosing nutritional disorder and fertilizer needs of vegetables, and control of weeds in vegetable crops; and zoology, including methods for the control of starlings.

**Fifty-eighth Annual Report of the South Carolina Experiment Station, [1945], H. P. COOPER ET AL.** (Partly coop. U. S. D. A.). (*South Carolina Sta. Rpt. 1945, pp. 166, illus. 35.*)—In addition to articles noted elsewhere in this issue results are presented of research in agricultural economics, including consumer preference for tree-ripened peaches and small packages, seasonality of cotton gin operations, efficiency in cotton production, and labor requirements for sweetpotatoes; agricultural engineering, including studies of mulch farming, tillage methods for corn following winter cover crops and to control erosion, and mulch farming v. clean tillage for cotton and oats; field crops and fertilizers, including variety tests of corn, oats, wheat, and soybeans, pH levels for oats and lespedeza hay, lime and fertilizer for white clover in pastures, and nitrogen sources for cotton; fruits and vegetables, including variety tests of peaches and pears and culture of Turkish tobacco; plant physiology and plant diseases, including mineral nutrition and wilt resistance in cotton, cotton and sweetpotatoes as reciprocal hosts of wilt fungi, Mexican clover as a carrier of the sweetpotato wilt fungus, control of the root knot nematode by soil fumigation, cotton and corn seedling diseases, breeding cotton varieties resistant to bacterial blight, fungi attacking fruits of cayenne pepper, and miscellaneous plant diseases; insects, including control of the rice weevil in stored corn and cowpeas, the cowpea curculio, oriental fruit moth, studies of honey-yielding plants, causes of bitter honey, DDT for fly control in dairy barns, summer squash insects, corn earworm, and Mexican bean beetle on beans; animal husbandry, including tests of sweetpotatoes for fattening swine, control of kidney worms in swine, cobalt content of pasture grasses and

forage crops, and protein content of wheat; dairying, including grazing heifers on sericea lespedeza and urea-treated v. untreated corn silage for lactating cows; poultry, including the sufficiency of vitamin E in standard chick rations and Korean lespedeza meal as a supplement in breeding rations; at the Coast Station, studies of pasture fertilizers, establishing kudzu on cut-over coastal pine land, Bermuda v. Dallis grass for erosion control on drainage canal spoil banks, and lespedeza sericea for hay on fire lines; at the Pee Dee Station, production studies of grain sorghums and tobacco, cayenne pepper and soybean varieties, plow sole application of fertilizer, mechanical cotton chopping, cotton breeding and genetics, control of boll weevil and cotton aphid, curing flue-cured tobacco, DDT for control of tobacco hornworm, tobacco budworm, tobacco flea beetle, and the tree cricket *Olcathus nigricornis*, and dusts for tobacco blue mold; at the Sandhill Station, kudzu for grazing lactating cows, nitrogen sources, potash salts, acid-forming v. nonacid-forming fertilizers, and sodium chloride v. potassium chloride, all for cotton; at the Truck Station, tests of new cabbage selections, improved varieties of paprika, lettuce and potato fertilizers, size of Katahdin seed potatoes and seed pieces and relation of spacing to yield, early v. late-emerging potatoes, and factors influencing potato scab; and at the Edisto Station, sweetpotato plant production, varieties of cotton, corn, oats, wheat, and barley, and cotton mechanization studies.

Twenty-sixth annual report [of the State of California Department of Agriculture for] period ending December 31, 1945 (*Calif. Dept. Agr. Bul.*, 34 (1945), No. 4, pp. 141-108+, illus. 3).—This report presents findings for the year in the divisions of plant industry, including the bureaus of entomology and plant quarantine, plant pathology, rodent and weed control and seed inspection, field crops, and chemistry; animal industry, including the bureaus of livestock disease control, dairy science, meat inspection, and livestock identification; and economics including the bureaus of markets, market enforcement, market news, milk control, agricultural statistics, fruit and vegetable standardization, shipping point inspection, and weights and measures.

### MISCELLANEOUS

California agriculture, edited by C. B. HUTCHINSON (*Berkeley: Univ. Calif. Press; London: Cambridge Univ. Press*, 1946, pp. 444+, about 60 illus.).—According to the editor's preface, "this is a story of California agriculture from the days of the Spanish missions to the middle of the twentieth century. It depicts particularly the rise of agriculture in an arid and semiarid land through the aid of science and engineering skill. It has been written as one of a series of volumes prepared in commemoration of the seventy-fifth anniversary of the founding of the University of California and records in some degree the contributions made by the university to the development of the agriculture and rural life of the State."

The successive chapters deal with The Historical Background of California Agriculture, by F. Adams (pp. 1-50); Wealth Pyramiding in the Production of Livestock, by G. H. Hart et al. (pp. 51-112); The Rich Pattern of California Crops, by W. P. Tufts et al. (pp. 113-238); Protecting Plants From Their Enemies, by R. E. Smith et al. (pp. 239-315); Exploring the Soils of California, by H. Jenny et al. (pp. 317-393); and The Economic and Social Structure of California Agriculture, by M. R. Benedict (pp. 395-435).

Mississippi Farm Research [March-April 1946] (*Miss. Farm Res. [Mississippi Sta.]*, 9 (1946), Nos. 3, pp. 8, illus. 6; 4, pp. 8, illus. 6).—In addition to the

monthly meteorological notes and several articles noted elsewhere in this issue, these numbers contain the following:

*No. 3.*—The Demand and Price Situation, by D. G. Miley (pp. 1, 8); Factors in Family Food Preparation, by D. Dickins (pp. 3-7), also to be published as a station bulletin; Field Shocked Sorghum as a Feed for Wintering Beef Cattle, by S. P. Crockett (pp. 1, 8); and Pasture Crops Require Adequate Supplies of Plant Food, by H. W. Bennett (pp. 1, 8).

*No. 4.*—Development of the Dairy Manufacturing Industry in Mississippi, by D. W. Parvin (p. 1); The Vitamin A Potency of Mississippi Creamery Butter, by F. H. Herzer and M. Gieger (pp. 3-4, 5), also to be published as a station bulletin; Better Living for Farm Families by Industrialization, by D. Dickins (p. 5), an abstract of Bulletin 364 (E. S. R., 87, p. 321); Mississippi Cash Farm Income for 1945, by D. W. Parvin (pp. 1, 6); Trends in Cotton Production in Mississippi, by H. P. Todd (pp. 6-7); and Milk and Butterfat Prices, 1929-1944, by D. W. Parvin (pp. 1, 8).

**Foreign Agriculture [August-September 1946]** (*U. S. Dept. Agr., Foreign Agr., 10 (1946), Nos. 8, pp. 105-120, illus. 5; 9, pp. 121-136, illus. 1*).—No. 8 includes the following articles: Chile's Pattern of Agricultural Production and Trade, Part 1, by P. L. Guest (pp. 106-114), and Agricultural Ruthenia, by F. S. Straus (pp. 114-120). No. 9 contains Cuban Agricultural Policy, by P. G. Minneman (pp. 122-128), and Chile's Pattern of Agricultural Production and Trade, Part 2, by P. L. Guest (pp. 129-136).

**Tentative directory of agricultural periodicals, societies, experiment stations, and schools in Latin America** (Washington, D. C.: Pan. Amer. Union. Div. Agr. Coop., 1945, pp. 90+).

**The agricultural development of the Middle East**, B. A. KEEN (*London: Govt., 1946, pp. 126+, illus. 17*).—This is a report to the Director General of the Middle East Supply Centre as a part of the survey for the Scientific Advisory Mission. It outlines the present status of Middle East agriculture by territories, and discusses the obstacles to agricultural improvement, methods of raising agricultural standards, scientific and technical problems, and the supply and development of agricultural information and advice.

---

## NOTES

---

**California University and Station.**—Dr. William B. Herms, head of the division of entomology and parasitology for 23 years and associated with the institution since 1908, has retired.

**Colorado College and Station.**—Dr. Nellie E. Goldthwaite, associate professor of home economics research from 1919 until her retirement in 1925 and a pioneer worker in home economics research, died in South Hadley, Mass., on November 25 aged 83 years. A recipient of the Ph. D. degree from the University of Chicago in 1904, she served as head of the chemistry department of Mt. Holyoke College from 1897-1905 and as associate physiological chemist in the Rockefeller Institute from 1906 to 1908. In the latter year she was appointed assistant professor in household science in the University of Illinois and in 1915 became head of the department of home economics in the University

of New Hampshire. Among her research projects were those dealing with the chemistry and physics of jelly making, the principles of bread making, and the chemical composition of Colorado potatoes.

**University of Minnesota.**—The board of regents of the university has accepted a gift of \$15,000 to establish The Conway MacMillan Memorial Research Fellowship in Botany, Charles J. Brand, 1902. Founder, with an annual stipend of \$1,200. The fellowship is available annually to doctoral students in botany having the master's degree from the University of Minnesota or institutions of similar standing. According to the terms of the gift, special mention is made of those from the University of Chile and the Catholic University of Chile. Mr. Brand plans to add to the fund, and hopes to interest other men and women who were trained by Professor MacMillan in making the fellowship permanent. A. Stanley Holt, Rhode Island State College, 1939, has been chosen as fellow for the first year; his field of research, leading to the doctorate, is the evolution of oxygen by chloroplasts in the presence of oxidizing agents. The founder of the fellowship is best known for his 20 years' work in the U. S. Department of Agriculture in research, administrative, and consultative capacities, his most recent service there having been as coadministrator of the Agricultural Adjustment Administration in 1933.

**Office of Experiment Stations.**—The retirement on December 31 is noted of Howard L. Knight, editor of *Experiment Station Record*, and Martha C. Gundlach, in charge of indexes. Mr. Knight had been associated with the Office since 1904, most of that and the following year being in connection with its nutrition investigations at Wesleyan University. Coming to Washington in 1906, he was assistant editor of the *Record* until 1918, associate editor until 1923, and subsequently editor of volumes 50 to 95, inclusive.

Miss Gundlach came to the Office in 1920. She had prepared volume indexes for volumes 42 to 93, inclusive, as well as combined indexes for volumes 26-40, 41-50, 51-60, and 61-70.

Dr. S. H. Work, animal husbandman in the Office of Foreign Agricultural Relations, has been appointed experiment station administrator (animal husbandry).

**U. S. Department of Agriculture.**—Reuben Brigham, assistant director of the Extension Service since 1937 and associated with the Department since 1917, died in Chicago on December 5 in his fifty-ninth year. A native of Massachusetts and a graduate of Maryland University in 1908, he served there as secretary to the president, editor, and agent in charge of the boys' club work and news service for 5 years beginning in 1913. In the Department he had been an assistant in publications in the States Relations Service and in charge of visual instruction and educational work in the Extension Service. He was president of the American Association of Agricultural Editors in 1924-25.

**Association of Land-Grant Colleges and Universities.**—The sixtieth convention of this association was held in Chicago from December 16 to 18, with the customary preliminary sessions. The revised constitution and by-laws adopted in 1945 became effective. Under the new plan of organization, the retiring president, Dean T. P. Cooper of Kentucky, became chairman of the executive committee for the ensuing year. President \* D. Hetzel of Pennsylvania was elected president of the association and vice chairman of the executive committee and Dean Russell I. Thackrey of the Kansas College executive secretary, the latter with headquarters in Washington, D. C.

# INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P. R. U." to those of the experiment stations in Hawaii and Puerto Rico (University station); and "U. S. D. A." to those of this Department.

- A L. 63, original British Army louse powder, 543.
- ANTU—  
du Pont rodenticide, alphanaphthylthiourea, 350.  
toxicity to chicks and pigs, 854.  
use as poison for common Norway rat, instructions, 350.
- Abortion—  
contagious—see also *Brucella abortus*.  
control by vaccination in New Zealand, progress, 244.  
equine infectious or epizootic, etiology, 719.
- Abutilon theophrasti*, Duvel buried seed experiment, final results, U. S. D. A. 201.
- Acalypha rhomboidea*, seed development, 797.
- Acaridae, order Acari, revision based on comparative morphological studies, I, taxonomic, 365.
- Acariscus masoni*, trombiculid mite, new host records, 522.
- Accidents, farm, avoidance, U.S.D.A. 724.
- Acenaphthene—  
in combination with X-rays, effect on plant tissue, 207.  
induction of mutation in phytopathogenic bacteria, 798.
- Acetic acid bacteria, characterization procedure, 635.
- Acetobacter*—  
infection, III, strains of *A. acetosum* isolated from pitching yeast and beer, 635.  
spp., capsule formation, 635.  
*suborydans* assay for *p*-aminobenzoic acid, modifications, 622.
- Acetone-benzene-water mixtures, analysis data for, 21.
- Acetonemia—see Ketosis.
- Acetyl groups, microdetermination in acetates of glycosides and sugars, 153.
- Acetyl phosphate, oxidation by *Micrococcus lysodeikticus*, 464.
- Acetylmethylcarbinol-water system, liquid-vapor equilibria, 767.
- 3-Acetylpyridine, nicotinic acid deficiency produced in mice by, 136.
- Acetyltryptophane, utilization by man, 593.
- Achondroplasia, dominant, recurrent mutation, in cattle, 799.
- Acid inversion of sucrose, 610.
- Acids, fatty—see Fatty acids.
- Acipenser fulvescens*, in Lake Winnebago, (Wis.) 76.
- Acrostalagmus zeosporus* n. sp., parasitizing nematode, 75.
- Acrosternum hilare*—see Green stink bug.
- Acrylic esters, emulsion polymerization of, 146.
- Actinomyces scabies*, infection studies, 343.
- Actinomycete, Meredith's, *Fusarium oxysporium cubense* inhibited by, 60.
- Actinomycetes, origin, hypothesis, 31.
- Adhesives, tacky and remolstening, peanut protein hydrates as, 164.
- Adrenocorticotrophic hormone, effect of various reagents, 611.
- Adsorption analysis of colorless compounds, techniques, 155.
- Aedes*—  
*aegypti* eggs, ovicidal value of chlorine, 368.  
*aegypti*, feeding through animal membranes, 227.  
*amesti*, larva and male, 698.  
*lepidus*, vector of *Plasmodium gallinaceum*, 87.  
new species from—  
Netherlands New Guinea, 698.  
New Guinea, 227.  
Okinawa, 87.  
*tortilis*, mosquito new to United States, 366.
- Aerobiology, relation to plant disease, 508.
- DDT, non-volatile content, effect on house
- Aerosol(s)—  
flies, 840.  
dispersed by liquefied gases, new formulations, 684.  
formation, tests of pyrethrum and DDT against common malaria mosquito and housefly, 541.  
heat-generated, for agricultural pests, preliminary studies, 78.  
insecticidal—  
containing DDT, accelerated aging test, 778.  
for pea aphid control, II, 692.

## Atmosols—Continued

- dispenser for testing, 77.  
evaluation, 78.  
particle-size distribution, 684.  
OT, use in preparation of microscopic mounts of fungi, 646.  
thermal fog generator for large-scale application of DDT and other insecticides, 654.  
thermol fogs, DDT, for clothes moths in wool storage warehouse, 697.  
African coast fever—see also East coast fever.  
Agar media, gas bubbles developing in, 30.  
*Agaphaeops nigra*—see Lily weevil.  
Agitator, centrifuge-tube, construction and operation, 149.  
Agricultural—  
crops—see Crop(s).  
education—see Education.  
experiment stations—  
of U.S.A., publications statistics (1945), U.S.D.A. 143.  
report on (1945), U.S.D.A. 142.  
extension—see Extension.  
geography, Philippine Islands, graphic summary, U.S.D.A. 262.  
perishables, air transport, U.S.D.A. 263.  
policies, postwar, U.S.D.A. 110.  
production—  
index numbers (1945), Ohio 110.  
postwar, U.S.D.A. 110.  
research progress reports, U.S.D.A. 140.  
products—  
distribution, postwar, U.S.D.A. 110.  
expanding uses, U.S.D.A. 140.  
freezing, locker and home, Wash. 418.  
production, prices, and income, index numbers, Ohio 872.  
research by experiment stations, progress reports (1945), U.S.D.A. 142.  
research, future of, U.S.D.A. 140.  
Agricultural and Industrial Chemistry, Bureau of, report of Chief (1945), U.S.D.A. 140, 141.  
Agricultural Finance Review, November 1945, U.S.D.A. 406.  
Agricultural Research Administration, notes, 608.  
Agricultural Research in 1944, farmer's guide, 444.  
Agricultural Statistics, 1945, U.S.D.A. 585.  
Agriculture—  
American, production and welfare objectives, 724.  
applications of climatology, 630.  
cropping, practice in West Highlands and Islands, book, 444.  
European, decline and recovery, World Wars I and II, U.S.D.A. 403.  
Foreign, February-March 1946, U.S.D.A. 263.  
in California, historical review, book, 910.  
of China, climatic effects, 23.

## Agriculture—Continued

- Oklahoma, looking forward, Okla. 865.  
postwar problems and programs in Nebraska, committee reports listed, Nebr. 110-111.  
postwar readjustments in Massachusetts, Mass. 564.  
price policy for promotion of income from farming, 581.  
production, income, and costs in Arizona, Ariz. 111.  
resources in West Virginia, conservation and use, 865.  
Agriculture in the Americas, 1946, U.S.D.A. 606.  
*Agilus anisus*—see Bronze birch borer.  
Agronomy—  
general, bibliography, 1940-44, 781.  
research—  
by experiment stations, progress reports (1945), U. S. D. A. 142.  
progress reports, U. S. D. A. 140, Ala. 143.  
*Agropyron*, *Elymus*, and *Sitanion* hybrids, artificial and natural, 645.  
*Agropyron* hybrids, artificial and natural, 798.  
*Agrostis* spp., aneuploids, morphological variations and occurrence in Rhode Island, 494.  
Air, condensation levels in, comparison of lower-cloud bases with, 28.  
Air transport of agricultural perishables, U.S.D.A. 263.  
Aircraft, DDT dispersion from, 79.  
Aircraft workers in southern California, nutritional status, I-IV, 418.  
Airplane—  
application of DDT for control of adult mosquitoes in open unwooded areas, 368.  
dusting of orchards practical, 72.  
spraying rice fields with DDT for mosquito larvae, 87.  
Alabama College, notes, 445.  
Alabama Station—  
notes, 445.  
report, 143.  
d(—)—Alanine, vitamin B<sub>6</sub> replaced for micro-organisms by, 158.  
*Alaria tarideae* n. sp. from badger and other mustelids, description, 522.  
Albumin, egg—see Egg albumin.  
*Alcaligenes radiobacter*, cause of galls on zinnia, 219.  
Alcohol—  
dehydrogenation, technique, 147.  
from wheat, malt-evaluation for, 166.  
metabolism, relation to production of thiamine deficiency, 600.  
motor fuels, iron pentacarbonyl as anti-knock agent in, 165.  
wood sugars fermented to, 162.  
Alcohol-hydrocarbon mixtures, water solubility in, 166.

- Alfalfa—  
 carotene content—  
   chromatographic determination, 157.  
   correlated with leafhopper resistance, 193.  
   dehydrated, assay by simplified technique, 17.  
 carotene-destroying system, enzymic nature, 768.  
 caterpillar, migrations in central U. S. A., 80.  
 decreases in Black Belt with decreases in soil fertility, Miss. 786.  
 growing practices, Mo. 193.  
 immunity to pea aphid, temporary, U. S. D. A. 822.  
 insect pollinators in California, 535.  
 new varieties, wilt resistance, Minn. 501.  
 production in Kansas, Kans. 805.  
 rhizoctonia root canker development, effect of soil temperature, U. S. D. A. 822.  
 seed production—  
   effect of lygus bugs, and their control by burning, 224.  
   effect of tripping, soil moisture, plant spacing, and lodging, 804.  
   honeybee role, Mich. 89.  
 seed, setting and production, effects of pollination, lygus infestation, genotype, and plant size, Miss. 804.  
 seed, water absorption and germination, effect of osmotic pressure, 488.  
 tripping by insects, Utah 688.  
 Algae, fresh-water, from Louisiana and Texas, 180.  
 Algae, pure cultures, preparation and maintenance, 637.  
 Alkaloids in cinchonas of Peru, U. S. D. A. 148.  
 Allegheny mound ant and control, 77.  
*Allium cepa*—see also Onion(s).  
   cytological effects of sulfanilamide, 324.  
*Alsophila pometaria*—see Fall cankerworm.  
*Alternaria*, Danish species, monograph, 60.  
 Aluminum dross, fertilizer value, 30.  
 Aluminum stearate, DDT penetration prevented by, 79.  
*Ambrosia artemisiifolia*, Duvel buried seed experiment, final results, U.S.D.A. 201.  
*Amelanchier* spp., American, monograph, 316.  
 American—  
   cockroach, arsenicals for, concentration-survival time relations, 85.  
   cockroach, nicotine penetration rates from solutions of various pH values, 77.  
   dog tick, vector of Rocky Mountain spotted fever, control, preliminary tests, 701.  
 American Farm Economic Association, committee on parity concept, survey of economists' views, 724.  
 American Meteorological Society, recommendations on teaching meteorology, 308.  
 American Phytopathological Society—  
   annual meeting, 1946, abstracts of papers, 334.  
   New England Division, 1946 meeting, report, 819.  
   Potomac Division, third annual meeting, report, 820.  
   report on vegetable seed treatments in 1944, U.S.D.A. 674.  
 American Society of Animal Production, index to Proceedings, 90.  
 American Society of Parasitologists, papers, abstracts, 331.  
 Amide synthesis in plants, amino-acid changes in germinating seedlings, 491.  
 Amino acid(s)—  
   administration to rats fed low protein diet, hemoglobin formation following, 593.  
   changes in germinating seedlings, 491.  
   deficiency, role in tongue deformity of chicks, 105.  
   effect on liver fat, 737.  
   in animal proteins, microbiological determination, 618.  
   microbiological assay, 14.  
   peptides, and proteins—  
   investigations, XXI, 618.  
   investigations, XXIII-XXV, 619.  
   protein contents, assay, 128.  
   *Streptococcus faecalis* requirements, 179.  
 $\alpha$ -Amino acids, reaction of ascorbic acid with, 626.  
*d*-Amino acids—  
   utilization by man, 128.  
   III-IV, arginine and acetyltryptophane, 593.  
   V, histidine, 736.  
*p*-Aminobenzoic acid—  
   assay—  
   *Acetobacter suboxydans*, modifications, 622.  
   *Leuconostoc mesenteroides*, 622.  
   effect on growth of legume, 183.  
 Ammonium—  
   molybdate, control of whiptail in cauliflower and broccoli crops in New Zealand, 512.  
 nitrate—  
   and organic matter in fertilizer mixtures, 30.  
   preparation for use as fertilizer, U.S.D.A. 682.  
   properties of granular and monocrystalline, 145.  
   nutrition, influence on nitrogen metabolism, 794.  
*Amorpha fruticosa*—see Indigobush.  
*Amphimallon majalis*, control in lawns, 696.  
 Amylase—  
   inhibitor—  
   cereals, distribution and general properties, 612.  
   wheat, mode of action, 613.  
   wheat, preparation and properties, 613.

## Amylase—Continued

sorghum, composition and traces in malt, 612-614.

-Amylase in barley malt, determination, modification of Kneen and Sandstedt methods, 473.

3-Amylase in barley malt, determination, modification of Kneen and Sandstedt methods, 473.

Amylopectin, separation by nitroparaffins, 15.

Amylose, separation by nitroparaffins, 15.

Anacardiaceae, Chinese gallnuts on trees of, general study, 37.

Analysis, adsorption, of colorless compounds, technique, 155.

## Ananas—

*comosus*, nitrogenous constituents, effect of potassium, 507.

*sativus*—see Pineapple(s).

*Anastrepha ludens*—see Mexican fruit fly.

*serpentina*, immature stages, development, relation to temperature, 537.

## Anemia—

absorption and utilization of ferrous vs. ferric iron in, radioactive-isotope determination, 130.

equine infectious, in brood mares and their offspring, 719.

in monkey, studies, 600.

in rats, correction by iron compounds, 596.  
infectious equine, acute, penicillin treatment, 247.

## Anemometer(s)—

cup, errors in fluctuating winds, 309.

hot-wire, sensitive, calibration characteristics, 309.

slowage indicators, 474.

*Anemone pulsatilla*, antibiotic (protoanemonin) from, 180.

Anesthesia, influence on experimental western equine encephalomyelitis, 719.

Anesthetic for horses, newly developed, 336.

Aneuploids, morphological variations and occurrence in *Agrostis* spp. in Rhode Island, 494.

1,4-Anhydro-D,L-xyitol, designation, 294.

Animal(s)—see also Livestock; specific kinds.

blood groups and transfusion in, 100.

breeding, experiments in England, book, 652.

breeds, heterozygosity reduced by inbreeding, 187.

carnivorous, *Physaloptera*, annotated list, 88.

cobalt in, determination with nitrosocresol, 151.

colonies, genetic purity, 187.

communities in Medicine Bow Mountains, ecological reconnaissance, Nebr. 219.

cytology, book, 41.

diseases, research—

by experiment stations, progress reports (1945), U.S.D.A. 142.

progress reports, U.S.D.A. 99, Ala. 143.

## Animal(s)—Continued

domestic

brucellosis, control progress, 854.

DDT toxicity for, 86.

hereditary abnormalities, 853.

farm, tolerance to feed containing 2,4-dichlorophenoxyacetic acid, 558.

feed supplement, fused tricalcium phosphate fertilizer, 841.

feeding chemicals for pest control, 527.

husbandry, research—

by experiment stations, progress reports (1945), U.S.D.A. 142.

needs, U.S.D.A. 140.

progress reports, U.S.D.A. 90.

insect pests, DDT tests summarized, 85.

laboratory, DDT toxicity, 86.

measurement, new instrument, 703.

meat, production and consumption in war and peace, U.S.D.A. 260.

"1080" poisoning, clinical observations, 720.

production inheritance, evaluation method, N.Y. (Cornell) 798.

production, principles, book, 89.

range, selenium poisoning, pathology, Wyo. 559.

*Salmonella* infections, 242.

Animal Industry, Bureau of, report of Chief (1945), U.S.D.A. 41 140, 141.

Annatto, reactions and properties as cheese color, II, 557.

## Anopheles—

*albimanus*, in Florida, 86.

*culicifacies*, bionomics, III, IV, 699.

*fluvialis*, behavior, IV, gravid females, 700.

mosquitoes of California, ability to transmit malarial of foreign origin, 228.

new species from Okinawa, 87.

*punctulatus*, complex 698.

*quadrinaculatus*—see also Common malaria mosquito.

laboratory rearing, 698.

spp.—

female, moonlight and house-haunting habits in West Africa, 867.

in brackish water on Pacific coast, 77.

in Brazil, 87.

in southern Michigan, Mich. 86.

## Anopheline mosquito(es)—

*Chagasia roseboomi*, description, 228.

distribution in Solomon Islands, 228.

Indian, adult bionomics, with special reference to malaria control by pyrethrum, 698.

Anoxia, anoxic, resistance, effect of toco-pherol and fat, 739.

Anoxia, effects on ascorbic acid excretion, acidity of urine, and survival of rats, 427.

## Ant(s)—

activity above ground, daily fluctuations of three species, 355.

collection, use of ether, 221.

host of fungus *Laboulbenia formicarum*, 221.

- Ant(s)**—Continued  
 new house-invading from Massachusetts, 355.  
 role in coincident infestations of soft and yellow scales, 77.
- Anthelmintic**, phenothiazine as, 101.
- Anthrenomus signatus** — see *Strawberry weevil*.
- Anthrax** on—  
 cannery tomatoes, control, two years' results, Mich. 677.  
 cucumbers, control by Fermate, 827.  
 on lespedeza, cause and symptoms, 671.  
 on snap beans, control by DDT dust, Mich. 360.
- Anthrax**—  
 in man, treatment by sulfadiazine, 242.  
 treatment with sulfadiazine, 242.  
 vaccine, avirulent, 715.
- Antibacillin**, naturally occurring inhibitor of bacillin, 314.
- Antibacterial activity** of protamine zinc insulin, 313.
- Antibacterial pigment** from *Fusarium javanicum*, 314.
- Antibiotic(s)**—  
 activity of extract of western red cedar heartwood, 483.  
 from *Aspergillus wentii*, effect on legume bacteria, 30.  
 from *Spiraea aruncus*, 483.  
 in Meredith's actinomycete, 60.  
 material from *Bacillus licheniformis* active against *Mycobacterium* spp., 313.  
 nature and action, review, 100.  
 production by fungi, 483.  
 research progress reports, U.S.D.A. 141.
- substance**—  
 assaying, agar-streak method, 304.  
 new, bacillin, from soil isolate of *Bacillus subtilis*, 314.
- Antibody-antigen reactions**, theory and corollaries, comparisons, 100.
- Antigens**—  
 cellular, individual differences between species hybrids, 190.  
 rapid, use against pullorum disease, 721.  
 segregation in bacterial culture by undescribed form of variation, 716.
- Antigen-antibody reactions** theory-corollaries—comparisons, 100.
- Antiliosol effect** of  $\lambda$ -hexachlorocyclohexane, 766.
- Antioxidant(s)**—  
 effect on linoleic acid autoxidation, N.Y. State, 147.  
 fat-soluble, estimation of total, 18.  
 for home-canned foods, 124.  
*d*-isoascorbic acid as, 124.
- Antiperspirant creams**, action on fabrics, 899.
- Antirachitic potency** of irradiated ergosterol (D2) and 7-dehydrocholesterol (D3) for growing pigs, 376.
- Antonoff's rule**, so-called, note, 471.
- Aonidiella citrina**—see *Yellow scale*.
- Apalocnemis**, new species, Nearctic, with identification keys, 534.
- Apanteles trifasciatus** n. sp., description, 831.
- Aphid(s)**—  
 Chinese gallnuts caused, 57.  
 cucurbit resistance, test, 81.  
 host records, annotated list, 831.  
 influence on carbohydrate exchange in cotton, 359.  
 on Canada wildrice, 360.
- Aphis middletonii**, attack on squash roots, 77.
- Aphonus castaneus** in Connecticut, 352.
- Aplodontia rufa**, new mite, description, 369.
- Aplomya caesar**, parasitization of European corn borer, 83.
- Apple(s)**—  
 blossom insects, control by DDT, 225.  
 blossom structure and setting of varieties compared, 50.  
 boron deficiency, observations at New South Wales, 516.  
 Brooks' fruit spot, fungicidal control by new organics, 72.  
 cold storage design, 577.  
 damage by plum curculio, effect of temperatures, 352.  
 drops after frost, prevention by growth substances, 51.  
 fruit maturity as influenced by naphthalene-acetic acid, 50.  
 fruit rots caused by *Penicillium*, 217.  
 industry, changes in Maine, Maine 579.  
 juices, canned, examination, 269.  
 Macoun, fruit set under adverse weather conditions, 1945, 331.
- McIntosh**—  
 freezing, use of calcium salts, 271.  
 leaves, color standards, [N.Y.] Cornell 816.
- mite**, control when DDT is used, 225.
- organoleptic tests**, 735.
- preharvest drop**, influence of naphthalene-acetic acid method, 51.
- preharvest drop retarded by naphthalene-acetic acid aerosols**, 50.
- production costs** in Hood River Valley, Oreg. 113.
- quality**, effect on price and rate of sale, [N.Y.] Cornell 730.
- scab**—  
 control, 827.  
 control sprays and dusts, application, machinery, 827.  
 fungicidal control by new organics, 72.  
 ground treatments, N.Y. State 72.
- self- and cross-pollination** of varieties compared, 50.
- sirup**, by ion exchange process, 161.
- tree pruning wounds**, treatment and healing in sound and winter-injured trees, [N.Y.] Cornell 831.
- varieties for western slope**, Colo. 331.
- vitamin C content**, effect of ripening, storage and other handling methods, Iowa, 898.

## Apricot(s)—

dried, deterioration, influence of temperature, 879.

dried, storage, gas changes and influence of oxygen on rate of deterioration, 879.

dried stored, deterioration, influence of moisture and sulfur dioxide, 878.

freezing in California, 881.

## leaf—

injury from fluorine deposit, 517.

scorch in Utah, Utah 678.

oxidation, control, 883.

*Aquilegia*, cultivated and wild, taxonomic monograph, 34.

## Argentina—

*Boophilus australis* control by gamma isomer of hexachlorocyclohexane, 700.

cultivated plants, pest, *Ligyra burmeisteri*, 687.

sugar beet, yellow wilt, U.S.D.A. 826.

Arginine, utilization by man, 593.

*Arilus cristatus*—see Wheel bug.

Armillaria root rot, development, relation to soil temperature, Calif. 209.

Arthropod pests of Cuba, 532.

*Artocarpus integra*, planting in Coconut Grove, Fla., 667.

Aryl arsonic acids, effect on experimental coccidiosis infection in chickens, 567.

Ascariasis in swine, 857.

*Ascaridia galli*, glycogen utilization, comparison in vitro and in vivo, 397.

Ascariids of swine, removal, efficacy of sodium fluoride, 718.

*Ascaris lumbricoides* var. *suis*, penetration of hexyl resorcinol, effect of surface substances, 242.

*Asclepias syriaca* pods, types found in Michigan, U.S.D.A. 797.

Ascomycetes, growth and fruiting, influence of carbohydrate in medium, 644.

Ascorbic acid—see also Vitamin C.

antioxidants for home-canned foods, 124.

concentration of Florida grapefruit, seasonal changes, 283.

## content of—

blood serum, determination, 626.

cabbage, availability in college women, Iowa 897.

cabbage, relation to environment and heredity, 890.

cabbage salads, 602.

cantaloup, effect of storage, Del. 895.

cauliflower, effect of steam and hot-water blanching, 281.

chile, effects of canning and drying, N. Mex. 889.

citrus juices, retention, 138.

dehydrated green beans, effect of blanching, storage, and cooking, 276.

food served in cooperative residence hall for women, 895.

fresh green peas, determination, 623.

freshly harvested vegetables, 602.

grapefruit juice, effect of commercial canning and short-time storage, 283.

## Ascorbic acid—Continued

## content of—continued

kale, effect of storage, Del. 895.

lima beans, frozen and canned, effect of home cooking, 746.

mango, relation to variety, 747.

potatoes, factors affecting, Nebr. 897.

potatoes, influence of variety, environment, maturity, and storage, 897.

sauerkraut, effect of processing and storage, 897.

snap beans, effect of steam and hot-water blanching, 281.

strawberries, varietal differences, La. 890.

summer squashes, 277.

sweetpotatoes, and storage losses, Ariz. 131.

sweetpotatoes, effect of curing, S.C. 891.

sweetpotatoes, effect of fertilizers, curing, storage, and cooking, Ga. and N.C. 742.

tangerines and factors influencing, Ariz. 137.

tomato varieties and retention in processed products, 603.

tomatoes at cannery, determination by field illumination and handling, 808.

tomatoes canned by five home-processing methods, La. 898.

tomatoes canned in home, 898.

vegetables, effects of icing, 895.

deficiencies, acute and chronic, in rhesus monkey, 283.

dye titration, specificity, 602.

excretion by sweat and urine under different environmental conditions, 740.

excretion, effect of food intake and anoxia, 427.

extra-dietary, effect of copper, 426.

ice cream as source, 131.

indophenol-xylene extraction method, and modifications for interfering substances, 626.

losses in large-scale cooking, Ala. 131.

oxidase, dietary, effect, 426.

oxidizing agent in doughs, 297.

prevention of browning in peaches, Ga. 735.

retention in marmalade during preparation and storage, 432.

*l*-Ascorbic acid, fatty acid monoesters in fats and oils, assay, 19.

Ash lace bug, *Leptotypha minor*, biology and control, 831.

## Asparagus—

harvesting by field-snapping method, Mich. 49.

seedling blight, N.J. 215.

stem tips, excised, culture in vitro, further experiments, 488.

wilt and foot rot, cause, 334.

*Aspergillus*—

*flavus-oryzae*, sterol production, with anti rachitic potency, 430.

*A. pergandii*—Continued

*niger*, growth, specificity of potassium and magnesium, 644.

*terreus*, itaconic acid production by, 163.  
*ventii*, antibiotics from, effect on legume bacteria, 80.

Association of Land Grant Colleges and Universities, notes, 288, 912.

## Aster—

China, wilt, investigation, 217.  
yellows—

identification with kok-saghyz yellows and relation to big bud in tomato, 210.

nonspecific transmission by leafhoppers, Calif. 363.

phlebotomid leafhopper vectors, Calif. 363.

## Atmosphere—

lower, relations with solar activity, 473.  
pollution by heavy industry, meteorological control, 780.

Atmospheric pressure upon insects, effects of variations, 685.

*Atricholaelaps sigmodoni* n. sp., mite on cotton rat, with notes on *Atricholaelaps* and *Ischnolaelaps*, 701.

Auger, soil, general purpose, Colo. 722.

Aujeszky's disease in Wisconsin, 715.

## Australia—

climatology, agricultural, 474.  
grasshoppers and locusts, 686.

*Austroicetes cruciata* eggs, parasite. *Scelio chortolcetes*, diapause, 533.

Automobiles, digester gas, 109.

Automotive engines, nonpetroleum fuels, 108.

Auxin-protein complexes of wheat grain, 485.

*Avena* spp., interspecific cross, inheritance of rust reactions, etc., 41.

Avocado fruit, respiration, effect of oxygen concentration, 666.

Avocado, virus disease, U.S.D.A. 58.

*Axine* genus, Trematoda, Monogenea, note, 387.

Azalea, petal blight, control, 74.

Azaleas, imported, leaf and twig blight, investigations, 217.

## Azobenzene—

efficacy in control of red spider mite on roses, N.Y. State and Cornell 356.  
use as acaricide and insecticide, 328.

*Azotobacter*, respiration, as influenced by substrate, 179.

Bacillin, inhibitor, naturally occurring, antibacillin, 314.

Bacillin, new antibiotic substance from soil isolate of *Bacillus subtilis*, 314.

*Bacillus*—

*brevis*, tyrothricin from, 148.

*cereus*—

nuclear material, 178.

penicillinase from, 32.

sporulation process, 178.

*licheniformis*, antibiotic material active against *Mycobacterium* spp., 313.

*Bacillus*—Continued

*licheniformis*, formation of carbon dioxide, and cultural method of detection, 553.

*polymyxa*, occurrence in Alberta soils, 339.

*subtilis*, antibiotic production, I, II. action and toxicity, 636.

*subtilis*, soil isolate, bacillin, new antibiotic substance, 314.

Bacon, overseas, preparation, retention of thiamine, riboflavin, and nicotinic acid, 279.

Bacon, processing, retention of thiamine, riboflavin, and niacin, 428.

## Bacteria—

aerobic mesophilic sporeforming, U.S.D.A. 635.

causing leaf and pod spots of snap and lima beans, overwintering in soil, 827.

cellulose-decomposing thermophilic culture, characteristics, 31.

coliform, chloramine effects as influenced by pH and temperature, 100.

diphtheroid, in bovine infectious pyelonephritis, 103.

distance dispersion rates, 208.

electrophoretic mobilities, influence of surface-active agents, 177.

enteric pathogenic, chloramine effects of pH and temperature, 100.

entomogenous, competition, 221.

growth rate, determination, simple photometric method, 313.

identification by means of bacteriophage, Ohio 684.

lactic acid, pyridoxine function, 179.

milk, reaction to—

penicillin, 552.

streptomycin, 852.

nuclear material, 178.

phytopathogenic, mutation due to acenaphthene, 798.

phytopathogenic, nutrition, 208.

sporulation process, 178.

stale-medium effects, 32.

sterilization methods, 99.

sucrose synthesis and utilization, mechanism and significance, 31.

sulfate-reducing, dyes inhibiting, practical applications, 32.

surfaces, electrokinetic studies, 177.

## Bacterial—

black chaff of wheat, diagnosis, 213.

blight of sugar beet, seed transmission, 673.

canker of stone fruit, 678.

cell, cytoplasmic membrane, morphology, nature, and functions, 31.

cultures, development, microcalorimetric study, 640.

galls of plants, and causal agents comparisons, 59.

growth in butter, effect of salt distribution, Iowa 95.

infections in rats, defense mechanisms, relationship to diet, 559.

## Bacterial—Continued

- infections, newer drugs, 853.  
 spoilage of canned meats, prevention by thermal processing, 268.  
 wilt, resistance of new alfalfa varieties, Minn. 501.
- Bactericidal activity of sodium hydroxide, influence of changes in concentration, 791.
- Bactericides, chloramine vs. chlorine, 100.
- Bactericides, for dairy industry, 99.
- Bacterin, autogenous, treatment of *Pasteurella multocida* infection in wild ducks, 398.
- Bacteriologist, great, Sergei Nikolaevitch Winogradsky, Sept. 1, 1856–Aug. 31, 1946, 780.
- Bacteriology—  
 dairy, papers, abstracts, 713.  
 elementary, textbooks, 633.  
 marine, book, 30.  
 papers, 634.
- Bacteriophage—  
 means of identifying bacteria, Ohio, 634.  
 nature, 483.  
 studies with cheese, 557.
- Bacteriostatic factor, in tomato fruits, 33.
- Bacterium coli*, phenol reaction with, temperature coefficient by new technique, 101.
- Bacterium translucens*, black pigment, tyrosinase factor, 63.
- Badger, duke, new species, description, 522.
- Baeria chrysostoma*, cultivation under sterile conditions, preliminary study, 640.
- Bahia grass types, 805.
- Bait(s)—  
 mixtures, poisonous, calculation, 521.  
 poison, use in locust campaign, 533.  
 rat, evaluation by field acceptance trials on Guam, 521.
- Bakelite varnish for honey extracting equipment, 702.
- Baking—  
 freezing batters and doughs before, 124.  
 ingredients, varietal responses in evaluation of protein quality of wheats, 306.  
 quality of wheat, weight and protein-content relation, 48.
- Bamboo(s)—  
 control of, soil erosion, 26.  
 leaf spot, caused by *Cilochorella bambusarum* n. sp., 679.  
 of China, new species and variety, 34.
- Bambusa tuldoidea*, curing relation to durability, U.S.D.A. 813.
- Banana leaf speckle in Jamaica, 519.
- Bang's disease—see Brucellosis.
- Bankhead-Jones Farm Tenant Act, farm ownership, financing under, La. 116.
- Barberry, destruction for cereal rust control, 63.
- Bark beetles, southern pine, informatory account, 84.
- Barley—  
 Bay, new variety, Mich. 656.  
 blights affecting production, 336.

## Barley—Continued

- cross, inheritance of stem rust reaction, nitrogen content of grain, and kernel weight, 648.
- cultivated, pollen tube, course, 805.
- eyespot in Scotland in 1944, 671.
- germinated, analyses, effects of variety and environment, 290.
- helminthosporium foot rot, 334.
- leaf rust, effect on quality and yield, 63.
- loose smut—  
 fungi in embryos, detection, 63.  
 incidence in West Virginia, seasonal, U.S.D.A. 58.
- malt, amylase content, determination, modified methods, 473.
- production in Nebraska, 822.
- production, leadership of North Dakota, N. Dak. 328.
- root-absorption of radioactive rubidium and phosphorus in, 36.
- seedling, nitrogen metabolism, aspects, relation of early growth to, 316.
- seed and seedling infection by *Xanthomonas translucens* var. *ceralis*, 510.
- varieties—  
 grown in U.S. and Canada in 1945, classification, U.S.D.A. 656.  
 performance tests (1945), N.C. 192.  
 reaction to wheat stem sawfly attack, 688.  
 spring, response to floral loose smut inoculation, 671.  
 winter, growing in New Jersey, N.J. 805.
- Barn(s)—  
 cleaners, types, aid to mechanization, Wis. 401.  
 dairy, insect control with DDT, 366.  
 milking, walk-in type, 578.
- Base exchange, in silicates, 145.
- Bast fibers, structure, properties, and preparation, 663.
- Batters, pastry, freezing before baking, 124.
- Bean(s)—  
 blackeye, in California, Calif. 502.  
 broad, powdery mildew caused by *Erysiphe polygoni* in Yunnan, China, 337.  
 castor. See Castor-bean.  
 diseases in Intermountain States, 1945, 335.  
 frozen green, vitamin retention in quantity food service, 889.  
 green, dehydrated, processing, effects on calcium, phosphorus, and ascorbic acid contents, 276.
- lima—  
 ascorbic acid content of frozen and canned, effect of home cooking practices, 746.  
 bush, promise, N.Y. State and Cornell 329.
- Lygus* bug injury in California, 675.  
 seed pitting by *Lygus* bugs in California, 691.  
 spots, leaf and pod, bacteria causing, overwintering in soil, 827.

- Bean(s)—Continued  
 lima—continued  
   vitamin studies, 888.  
   vitamin B<sub>1</sub> preservation, Miss. 743.  
   mosaic, new, in Idaho, Idaho 210.  
   mosaic virus, common, association with *Xanthomonas phaseoli*, II, III, 823.  
   mung—see Mung beans.  
   plants, histological responses to phenyl-acetic acid, 319.  
   plants, respiration, solid matter, and water relations, effect of 2, 4-dichlorophenoxyacetic acid, 320.  
   red kidney seed, special problems, N.Y. State and Cornell 329.  
   resistance to—  
   anthracnose, 512.  
   mosaic, 512.  
   weevil attack, 512.  
   sclerotinia rot disease in Idaho, 335.  
   snap—  
   ascorbic acid content, effect of steam and hot-water blanching, 281.  
   dusting for control of anthracnose and leafhoppers, year's results, Mich. 360.  
   freezing, rate, effect on appearance, palatability, and vitamin content, 880.  
   growing, costs, returns, and practices, on Cumberland Plateau, 1944, Tenn. 404.  
   nutritive value, 423.  
   spots, leaf and pod, bacteria causing, overwintering in soil, 827.  
   vitamins as influenced by home freezing and cooking, 132.  
   string, canning, bud, blossom, and pod drop reduction by plant hormones, 675.  
   varieties, selection by beet leafhopper, and relation to curly top, 833.  
   virosis in Montana, 334.  
   yields, effect of calcic and magnesian diluents of calcium arsenate, 689.
- Bed bugs—  
 exposed to DDT, effect of temperature, 227.  
 resistance to DDT, biological factors, 365.
- Bee(s)—see also Honeybees.  
 diseases, incidence and distribution in Britain, 89.  
 feeding for comb production, 369.  
 legume seed-production role, Mich. 88.  
 movement in edge of cluster, 89.  
 pollen substitute, supplying by dry feeder, Ohio 369.  
 protection from DDT, N.C. 702.  
 queen, life, book, 369.  
 queen, performance, 701.  
 repellents, materials for, 89.  
 saving, practical account, Colo. 702.  
 secretion of wax, 369.  
 winter cluster temperature, 89.
- Beech, European, leaves, morphology and water economy, modifications caused by frost during foliation, 347.
- Beech, susceptibility to drought and adverse winter conditions, 668.
- Beef—  
 canning, Ga. 269.  
 freezing temperature, relation to histological characteristics, tenderness, and drip losses, 271.  
 histological characteristics, tenderness, and drip losses, relation to freezing temperature, 271.  
 muscle meat, protein value, comparison with buffalo and goat, 275.
- Beekeeping and diseases, research progress reports, U.S.D.A. 141.
- Beer—  
 "percentage concentration," conversion to gallonage, 166.  
 vitamins added, stability, 424.
- Beet(s)—  
 carrion beetle infestation in Switzerland, 359.  
 frozen—  
   decay, 184.  
   fructosan-synthesis mechanism in, 184.  
   viscous rot, causal organism, *Phytomonas betae-gelatae* n. sp., description, 673.  
 leafhopper, ability to regain lost vitality by transfer from unfavorable to favorable host plants, 359.  
 leafhopper, selection of bean varieties, and relation to curly top, 833.  
 molasses, cattle fattening by, Wash. 91.  
 mosaic, aphids as vectors, 70.  
 nematode, soil populations as influenced by cropping, 70.  
 sidedressing with salt, results, N.Y. State and Cornell 814.  
 yellows, aphids as vectors, 70.
- Beetles, in stored products, monograph, 85.
- Begonia semperflorens*, inheritance in, 40.
- Benzene hexachloride—  
 for control of cotton insects, 535.  
 in grasshopper baits, 686.  
 house fly larval control by, 77.  
 significance in agriculture, 528.  
 ("666")—  
   insect control in canning industry, 85.  
   preliminary experiments, 223.
- Benzene-acetone-water mixtures, analysis, data, 21.
- Benzenes,  $\alpha$ -trichloromethyl-substituted, in codling moth larval control, 77.
- Benzoyl-D-(—)-alanine, unreactivity toward formaldehyde, and methylene bridges, 764.
- Betacocci, production of diacetyl in milk, effect of rancidity, 554.
- Betaine, isolation from guayule, 3.
- Bibliography of—  
*Anopheles darlingi* as malaria vector, 87.  
 antibiotics, nature and action, 100.  
 bacterial plant galls, comparisons of causal agents and, 59.  
 beetles in stored products, 85.  
 colchicine research, 185.

## Bibliography—Continued

- fertilizer use and crop yields, U.S.D.A. 790.  
 fungicidal action of copper, 62.  
 growth substances in plant diseases and causal agents, 59.  
 physiologic specialization in plant-pathogenic fungi, 60.  
 plant disease introduction prevention, 58.  
 plant respiration, 37.  
 potato in health and disease, 47.  
 Puerto Rican literature, 1493–1930, P.R.U. 757.  
 respiration in plants, 37.  
 root diseases of fruit trees, 72.  
 soil science, fertilizers, and general agronomy, 1940–44, 781.  
 tobacco marketing and manufacturing margins, U.S.D.A. 115.  
 tulip virus, diseases, 75.  
 virus infection and reproduction, 58.  
*Xanthomonas translucens* parasitism on Gramineae, 62.  
 Big bud, in tomato, relation to yellows of kok-saghyz and aster, 210.  
 Bimonthly Bulletin, March–April 1946, N. Dak. 444.  
 Bindweed, eradication by controlled grazing, Minn. 505.  
 Bindweed, field, variations in, 49.  
 Bins, turnip, storage with force ventilation, progress report, Ohio 862.  
 Biochemical research, currents, treatise, 761.  
 Biochemistry, subjects related to enzymology, advances, VI, 762.  
 Bioclimatics, of insect life, 169.  
 Biological—  
   assays, confidence limits, 757.  
   materials—  
     citric acid assay in, 14.  
     cobalt in, determination with nitroresol, 151.  
     pyridoxal contents, 158.  
     pyridoxamine contents, 158.  
 Biotin—  
   assay, *Lactobacillus arabinosus*, growth stimulants, 429.  
   assay, microbiological, growth stimulants, 429.  
   biological activity of related compounds and, 134.  
   biosynthesis, desthiobiotin, 615.  
   content in dairy products, microbiological assay, 20.  
   deficiency, egg-white induced in rats, aggravation failure of succinylsulfathiazole, 429.  
   deficiency syndrome in pigs fed desiccated egg white, 377.  
   human, metabolism on various levels of biotin intake, 744.  
   microbiological assay, stimulants for, 159.  
   synthetic (and related forms), activity for chick, 134.  
   2,2'-Bipyridine, iron inactivation and effect on riboflavin synthesis by *Clostridium*, 31.  
 Bird(s)—see also specific kinds.  
   banding activities in Indiana (1941–44), 76.  
   building in shrubs, nesting heights, 350.  
   domesticated, flagellates, I, behavior of *Trichomonas gallinarum* in culture, 722.  
   eastern, field book, 683.  
   Elateridae eaten in Utah, 77.  
   fall (1945) migration notes for U.S.A., 75.  
   galliform and passeriform, gapeworm infection in New York State, 369.  
   helminth parasites in western Massachusetts, 830.  
   lice of rodents, descriptions, 88.  
   migration, trans-Gulf, evidence, 522.  
   of beech-maple-hemlock community, breeding, 829.  
   racial variation, significance to wildlife management, 522.  
   summer, of Okoboji region, 1938–42, 523.  
*Bionella hollandi*, distribution in Solomon Islands, 228.  
 Biscuits, making for canning, 416.  
 Biscuits, ration, II–III, keeping quality, factors, 416.  
 Blackberry leaf mite, loganberry dry-berry disease role, 77.  
 Blackbird, species, study, 221.  
 Blackflies, larvicidal control by DDT, 88.  
 Blackhead disease of turkeys, control by phenothiazine, limitations, 569.  
 Blanching—  
   by electronics, new principles, 272.  
   effect on ascorbic acid content of snap beans and cauliflower, 281.  
   of fruits, by steam vs. sulfur, 126.  
   of vegetables, electronic method, 125.  
 Blankets, fiber content and care, effect on resiliency, thickness, and thermal conductivity, 750.  
 Blast furnace slags, neutralization value, titration, 13.  
*Blatta orientalis*—see Oriental cockroach.  
 Bleeding, aseptic, of animals, method, 387.  
*Blissus leucopterus*—see Chinch bug.  
 Blood—  
   constituents, changes in diseases of ruminants, 560.  
   groups in veterinary practice, 100.  
   of cows, contents under various physiological conditions, 383.  
   plasma—  
     carotene and vitamin A forms, 132.  
     iodine, determination, 771.  
     of dogs, determination of free leucine, isoleucine, valine, and threonine, 618.  
     proteins, changes produced by heat in presence of sugars, electrophoretic analysis, 765.  
     tocopherols, determination, simplified hydrogenation technique, 627.

## Blood—Continued

- serum—
  - albumin, tyrosine iodination, 3.
  - ascorbic acid content, determination, 626.
  - changes produced by heat in presence of sugars, electrophoretic analysis, 765.
  - transfusion in veterinary practice, 100.
  - tryptophan, microbiological assay, 15.
- Blossom midge, identity and host plants in Hawaii, 831.
- Blowflies, physiology and toxicology, studies, X, XI, 541.
- Blueberry (ies)—
  - cultivated—
    - insects, 84.
    - soil-reaction effects on growth and production, 53.
    - survey of industry in New Jersey (1944), 53.
  - dusting for control of cranberry fruit-worm, 836.
  - frozen, home processing and use, 882.
  - plant, diseased, eradication, 518.
  - stunt disease, insect carriers, 518.
- Bluegill, scale dimensions, means of calculation of fish conditions, 350.
- Bluegrass—
  - Kentucky, morphological variation in relation to breeding behavior, 197.
  - pastures, yield, estimation by clipping vs. grazing of dairy heifers, 850.
  - terrace outlet channel design, 722.
- Bluestem grass, utilization in maintenance of commercial cow herd, progress report, 373.
- Boars, *Brucella suis* isolation from semen, 717.
- Bodega Cooperative Creamery Incorporated, reorganization, proposals, Calif. 408.
- Body, human—see Human body.
- Boehmeria nivea*—see Ramie.
- Bone—
  - carbonate, relation to composition of blood and diet of rat, 421.
  - composition, relation to blood and diet of rat, 421.
  - development, need for manganese in rat, 421.
  - fluorine content, assay, 19.
  - growth in pigeons, X-ray effects, 47.
- Book(s) on—
  - agricultural development of Middle East, 911.
  - agriculture in California, 910.
  - animal cytology and evolution, 41.
  - animal production, principles, 89.
  - artificial insemination of Merino sheep, 187.
  - biochemical research developments, 761.
  - bovine trichomoniasis, 245.
  - Brazil, people and institutions, 119.
  - broiler production, 93.
  - carbohydrate metabolism in humans, 887.
  - chemistry of food and nutrition, seventh ed., 410.

## Book(s) on—Continued

- chromosome atlas of cultivated plants, 648.
- climatology for advanced students, 474.
- crofting agriculture, practice in West Highlands and Islands, 444.
- Danish species of *Alternaria* and *Stemphylium*, 60.
- drug plants of Mexico, 181.
- dyes employed in biological laboratory, 778.
- eastern birds, 683.
- egg production, battery, practical guide, 706.
- elementary bacteriology, 633.
- entomological nomenclature and literature, 532.
- farm buildings, 862.
- farm mechanics, 722.
- food and nutrition for young people, 418.
- forset soils and forest growth, 630.
- fungicides and their action, 61.
- geology (rocks and rivers), 143.
- Glossina* spp. of French West Africa, 700.
- hardwoods of South, 507.
- herbal of Rufinus, reprinting of 13th century manuscript, 30.
- home economics, omnibus, 410.
- house building, 724.
- household refrigeration, 724.
- leaf analysis as basis for determination of fertilizer needs of soil, 321.
- marine microbiology, 30.
- mechanic's handbook, 108.
- meteorology, dynamic, 308.
- microscope technique, 11.
- milk, condensed and powdered, 558.
- milk, secretion, 383.
- mineral resources, 143.
- nutrition and chemical growth in childhood, 274.
- onion production, 815.
- organic chemical syntheses, 1.
- pigeons, 711.
- plant immigrants and stowaways, 637.
- plants of Hawaii National Park illustrative of plants and customs of South Seas, 315.
- potato in health and disease, 47.
- poultry production, 234.
- practical cookery and etiquette of serving table, 267.
- protozoology, 77.
- queen bee, life, 369.
- rocks and rivers, 143.
- rural social organizations in U. S., Latin America, and Germany, 409.
- sewing fabric furnishings for home, 435.
- sex hormones, biological action, 188.
- slatted floor barn hay driers, 862.
- soil conservation, 26.
- soils and soil management, 24.
- spermatophytes of Dominican Republic, 181.
- trace elements, 29.
- turkeys, 380.

- Book(s) on—Continued  
 veterinary toxicology, Lander's, 386.
- Boophilus australis*, control by gamma isomer of hexachlorocyclohexane in Argentina, 700.
- Borax fertilizer for tobacco, Conn. [New Haven] 662.
- Boric acid, titration in presence of mannitol, 300.
- Boron—  
 compounds, solubility in plants, 184.  
 concentrations, effects on development of *Taraxacum kok-saghyz* in sand cultures, 491.  
 deficiency in—  
   apples, observation at New South Wales, 516.  
   pears, symptoms and control, 678.  
   plant-nutrient value and interrelationships, 29.  
   requirement of plants, relation to photoperiod, 796.  
   role in tobacco fertilization, 788.  
   supplements, response in rats fed rations low in potassium, 273.
- Bos indicus*, roughage digestibility, crude fiber effects in cattle vs., 91.
- Botrytis cinerea*, damage to lemons, and control, 346.
- Botrytis*—  
 disease in California, 335.  
*gladiolorum* n. sp., gladiolus corm rot due to, 74.  
 mold in lemons in Ventura County, 347.  
 rot on lemons, effect, 347.
- Bottles, weighing, rapid-closing device, 10.
- Bracken, poisonous properties, 393.
- Brassica*, taxonomic characters, evaluation with key to species and varieties, I, characters, 638.
- Brazil, anopheline mosquitoes, 228.
- Brazil, tea production, U.S.D.A. 666.
- Bread—see also Dough.  
 baking quality of dry milk solids, 411.  
 doughs, freezing before baking, 124.  
 enriched, iron in assay by rapid method, 19.  
 making, experimental, mixing time, optimum vs. fixed at various potassium bromate levels, 306.  
 mold prevented by electronic method, 126.  
 molds, spores, ultra-violet irradiation, 323.  
 U. S. Army, composition and vitamin retention, 122.  
 volume, effect of mixing speed and dry milk solids, 306.  
 white, enrichment, symposium, 876.  
 yeast, concentrated nutritious loaf, Mo. 411.
- Breeding—  
 livestock, progress report, U.S.D.A. 41.  
 method, for potato, Minn. 186.  
 plant—  
   pollen-excess advantageous, 37.  
   research progress reports, U.S.D.A. 141, 142.  
   research progress reports, Ala. 143.
- Brewing industry, applied entomology, 85.
- Bristles, artificial, from proteins, 163.
- Broadbean, germination, enzymes, 640.
- Broadbean, new disease due to *Phoma* sp. in Peru, 671.
- Broccoli crops, whiptail control by ammonium molybdate, 512.
- Broilers—  
 production, costs and returns, Maine 580.  
 successful growing, book, 93.  
 thiouracil effects on growth and fattening, 46.
- Bromegrass, seed and seedling infection by *Xanthomonas translucens* var. *cerealis*, 510.
- Bronze birch borer, as pest in Maine, informative account, 84.
- Brucella*—  
*abortus*—see also Abortion, contagious.  
   agglutinins, transference from cow to calf and persistence in calf's blood, 391.  
   cows infected with, changes of serum phosphatase level, 390.  
   dissociation, inherent and environmental factors in bacterial variation, 560.  
   strain 19, comparison with 45/20, 390.  
   strain 19, immunizing value, 390.  
   strain 19 vaccine, agglutinin response, relation to dosage and site of inoculation, 390.  
   strain 45/20, comparison with strain 19, 390.  
   strain 45/20, vaccination trials with live cultures of, 102.  
 infection, immunization of guinea pigs, 244.  
*melitensis*, occurrence and source in Iowa, 101.  
 organisms, culturing from blood clots, 244.  
*swis*—  
   cause of orchitis in swine, 565.  
   isolation from boar's semen, 717.  
   transmission from swine to cattle under pasture conditions, 394.
- Brucellosis—  
 bovine, opsonocytaphagic test in, 102.  
 control in domestic animals, progress, 854.  
 in dairy herds, control and its relation to milk supply, 716.  
 vaccine from strain 45 (20), field trials, 102.
- Bruchus pisorum*—see Pea weevil.
- Bruchus quadrimaculatus*—see Four-spotted pea beetle.
- Buffalo(es)—  
 gnats, larvicidal control by DDT, 88.  
 muscle meat, protein value, comparison with beef and goat, 275.  
 water, virus encephalomyelitis in China, 104.
- Buffalo grass seed, development, 658.
- Bufoninae, nematode parasites, 351.
- Bugula neritina*, attachment and growth, toxicity of copper, 358.

**Building(s)—**

construction, applications of climatology, 630.

**farm—**

structure program, needs, 257.

textbook, 862.

wiring and lighting, U.S.D.A. 257.

frames, steel, cost, saving in electric welding, Wis. 400.

**Bulls, Friesland, breeding value in South Africa, 496.**

**Bulls, weight, estimation from heart girth measurements, 238.**

***Bunostomum trigonocephalum*—**

heavy infections, probable origin, 717.

infections in lambs fed adequately, pathogenicity, 563.

**Burning of longleaf-slash pine type, effect on grazing, 57.**

**Bushes, disease eradication, 518.**

**Butadiene, from 2, 3-butylene glycol, 164.**

**1, 3-Butadiene, 2, 3-butylene glycol—**  
converted to, by pyrolysis of diacetate, 165.

converted to, pilot-plant trials, 165.

**2, 3-Butanediol, production from acid-hydrolyzed starch, 766.**

**Butter—**

Arizona, vitamin A content, 278.

bacteriology, study VIII, Iowa 240.

**fatty acids—**

effect on carotene utilization, 132.

nutritive value, 132.

keeping quality in storage, effect of temperature level, 556.

market, vitamin A and carotene content in Kansas, 892.

packing and storage, V, effect of temperature level on keeping quality, 556.

salt content, estimation by mercurimetric method, 621.

salt distribution and effect on bacterial growth, Iowa 240.

**vitamin A potency—**

in Louisiana, two-year study, 891.

of creamery, in Minnesota, 133.

wrapping in *Pinus radiata* boxes, use of parchoil and Pliofilm, 556.

**Butterfat—**

content of milk, variation, causes, 714.

cost of production in Utah, Utah 726.

needs of young calves, 382.

vs. margarine, in Sherman diet B, effect on growth and reproduction of rats, 129.

**n-Butyl mesityl oxalate, photochemical dimerization, 4.**

**2,3-Butylene glycol—**

acetylation, continuous process, 164.

conversion to 1,3-butadiene—

by pyrolysis of diacetate, 165.

pilot-plant trials, 165.

in fermentations, assay technique, 16.

recovery from fermentation liquors, 164.

water mixtures, liquid-vapor equilibrium, 164.

**Cabbage—**

ascorbic acid availability in college women, Iowa 897.

ascorbic acid content, relation to environment and heredity, 896.

maggot, control by DDT, 357.

salads, ascorbic acid content, 602.

yellows-resistant varieties, ascorbic acid content, 334.

**Cables, submarine, bacterial corrosion, prevention, 32.**

**Cakes—**

finished, quality, effect of method of combining ingredients, 876.

recipes for different altitudes, 267.

***Calamagrostis* spp., Scandinavian, genesis, 651.**

***Calandra oryzae*, oviposition, influence of temperature, humidity and density, 226.**

**Calcite grit, supplement to chick starting ration, 551.**

**Calcium—**

absorption by peanuts from kaolin and bentonite, 787.

arsenate diluents, calcic and magnesic, effect on bean yields, 689.

content of dehydrated green beans, effect of blanching, storage, and cooking, 276.

**dietary—**

influence of different levels upon egg-shell thickness, 708.

utilization, effect of cocoa, 594.

intake level, influence on complete life cycle of albino rat, 739.

metabolism of preschool children, 595.

pantothenate, absorption and excretion by dogs, 601.

silicate slags, neutralization value, titration, 13.

sources for laying chickens during hot weather, 551.

**Calf(ves)—**

ascorbic acid, vitamin A, and spinal pressure relationships, 232.

blood, persistence of *Brucella abortus* agglutinins after transference from cow, 391.

dairy, young, value of supplementary vitamins, 382.

diseases and treatment, 855.

dry starters, distillers' byproducts and sorbean meal, Nebr. 237.

lungs, embryonal mixed tumor, 387.

**newborn—**

carotene utilization, 552.

vitamin A reserves, effect of prepartum diet of cow, 332.

**nodular worm infections during prepatent period, 338.**

raising, modern methods, 238.

scours, infectious, control, 103.

spinal pressure, vitamin A, and ascorbic acid relationships, 232.

steer, fattening, comparison of dried sweet-potatoes, wheat, and corn, progress report, 374.

- Calf(ves)—Continued  
 vitamin A, ascorbic acid, and spinal pressure relationships, 232.  
 vitamin A requirements, 374.  
 wintering well, progress report, 374.  
 young, butterfat needs, Minn. 382.
- California agriculture, history, 910.
- California Station—  
 notes, 288, 912.  
 report, 1945, Calif. 910.
- California University, notes, 288, 912.
- Calliphora erythrocephala*, life tables, 656.
- Caloric value, of diets, Atwater system of calculation, 180.
- Camellia—  
 dieback, cause and control, Miss. 829.  
 flower blight, 347.
- Camphor, onion root responses, to, 183.
- Campylotropis* n. spp. in Asia, 34.

 foods, values, measurement by storage of vitamin A in rats' livers, 278.  
 green fodder, vitamin A activity, 545.  
 hay, preservation by autoclaving and waxing, Wis. 297.  
 ice cream, 131.  
 kale, availability, 598.  
 market butter produced in Kansas, 892.  
 nutrition of guinea pig, 597.  
 plant extracts, effect of storage, 892.

- Carotene—Continued  
 in—continued  
   plants, determination, 154.  
   rations for sheep and cattle, progress report, 373.  
   rose hips, 424.  
   stored leaf meals and extract, losses, 231.  
   summer squashes, 277.  
   sweetpotatoes, Ariz. 131.  
   sweetpotatoes, effect of curing, S.C. 891.  
   sweetpotatoes, effects of fertilizers, curing, storage, and cooking, Ga. and N.C. 742.  
   vegetables, physiological availability rat, 598.  
   vegetables, value for growth of white rat, 597.  
 losses in large-scale cooking, Ala. 131.  
 preservation, antioxygenic synergism of tocopherol and rice bran extract, 743.  
 rapid determination, apparatus, 298.  
 stabilization by nordihydroguaiaretic acid and other antioxidants, 466.  
 utilization—  
   by fox pups, comparison with vitamin A, 521.  
   by newborn calf, 552.  
   influence of fatty acids of butter, 132.  
 Carotene-destroying system of alfalfa, enzymic nature, 768.  
 $\alpha$ -Carotene B, stability and activity, 615.  
 $\beta$ -Carotene—*see also* Neo- $\beta$ -carotene.  
   highly pure, preparation, 297.  
   isomerization, effect on optical density ratios, 157.  
   vs. cod liver oil, U. S. P. reference, standards in vitamin A assays, 470.  
 $\gamma$ -Carotene, absorption spectrum, 615.  
 Carotenoid(s)—  
   and vitamin A levels in cattle, 232.  
   content of—  
     carrots, assay by simplified technic, 17.  
     dehydrated egg, 775.  
     peaches, effect of processing, S.C. 891.  
*Carpocapsa pomonella*—*see* Codling moth.  
 Carrion beetles of beet in Switzerland, 359.  
 Carrots—  
   blanched, vitamin retention, alcohol-insoluble solids as reference base, 775.  
   carotene, crude, constituents, 278.  
   carotenoids in, assay by simplified technic, 17.  
   production in West and Southwest, U.S.D.A. 815.  
   varieties, susceptibility, relative, to nematode damage, yellows, and defoliation, Ohio 343.  
   weed control by oil sprays, Mich. 328, [N.Y.] Cornell 330.  
 Casein—  
   bristles from, 163.  
   effect on pyridoxine-deficient mice, 128.  
   iodinated, experiments on farms in England and Wales, 712.  
 Casein—Continued  
   raw and heated, effect of proteolytic enzymes, 449.  
   textile fibers from, 163.  
   vegetable protein-solution viscosity patterns compared to, 2.  
 Cassava pith, superior for free-hand sections, 493.  
 Castor-bean hybrids, making, use of natural crossing plot, 806.  
 Castor oil, stearic acid preparation, 611.  
 Cat, domestic, normal blood count, 248.  
 Cats, enteric infections, sulfathalidine treatment, 248.  
 Catalyst, copper-chromium oxide, preparation and reclamation, 146.  
 Cattle—*see also* Ruminants.  
   achondroplasia, dominant, recurrent mutation, 799.  
   adaptability to tropical and subtropical climates, 703.  
 beef—  
   fattening rations in Montana, Mont. 842.  
   feeding tests, progress reports, 373.  
   grazing, July-planted Hodo sorghum unsatisfactory after frosts, Miss. 233.  
   heritability of growth and efficiency, 42.  
   heritability of live animal scores, grades, and carcass characteristics, 824.  
   industry in Gulf Coast States, 703.  
   measurements, relation to weights, 842.  
   weights, relation to objective measurements, 842.  
 blood levels of calcium and inorganic phosphorus, U.S.D.A. 546.  
*Brucella suis* infection from swine in pasture, 394.  
 brucellosis, opsonocytaphagic test, 102.  
 carotenoid and vitamin A levels, 232.  
 contagious disease associated with *Leptospira*, 561.  
 dairy—  
   artificial breeding, practicality, 42.  
   artificial insemination, Mo. 98.  
   blood, total ketone bodies, 238.  
   breeding efficiency in artificial insemination, influence of age, 496.  
   breeding, progress report, 42.  
   cross-breeding, 652.  
   feeds, digestibility, 712.  
   insemination, artificial developments, 800.  
   ketosis, experimental, 560.  
   ketosis, practical discussion, 560.  
   ketosis, studies VII and VIII, 239.  
   polikilocytosis, therapeutic effect of yeast and pyridoxine, 382.  
   rations, defluorinated rock phosphate as phosphorus supplement, 712.  
   research progress reports, U.S.D.A. 97.  
 deficiency diseases, therapeutic effect of small doses of cobalt in Norway, 563.  
 diseases, research progress reports, U.S.D.A. 99.

Cattle—Continued  
fattening—

- input-output relationships, 725.
- rations, Ariz. 90, Wash. 91.
- feeds, identification and passage through rumen, 841.
- fetal membranes, retained, blood picture, 854.
- grazing, use for measuring pasture yields, 373.
- healthy, peripheral blood, tick-transmitted protozoa in, 392.
- Holstein, history and development in Frederick County, Md., 712.
- infectious pyelonephritis, diphtheroids associated, 103.
- lead poisoning, 245.
- lice, biology and control, [N.Y.] Cornell 838.
- measurements, standardization, 703.
- molybdenum poisoning, 393.
- poisoning by *Lantana*, 855.
- pregnancy test, colostrum, 652.
- range, horn flies and Gulf coast ticks, control by DDT, 542.
- Red Poll pedigree population, growth and distribution in England, 496.
- research progress reports, U.S.D.A. 90.
- roughage digestibility, crude fiber effects, 91.
- selective breeding, duration of pedigree herds, 495.
- ticks, control by DDT-rotenone combination in tropical regions, 543.
- tuberculin test, intradermal, reaction, blood leucocyte picture, 563.
- vaccinated with *Brucella abortus* strain 19, immunity, 390.
- vitamin A and carotenoid levels, 232.
- zebu, roughage, digestibility, crude fiber effects, 91.

## Cauliflower—

- ascorbic acid content, effect of blanching, 281.
- whiptail control by ammonium molybdate, 512.
- worms, control on Long Island, 691.

## Cecal worms in turkeys, control by phenothiazine, limitations, 569.

## Cedar—

- Bermuda, insects and pests attacking, survey report, 364.
- northern white, in Maine, preliminary observations, 333.
- western red, heartwood extract, antibiotic activity, 483.

## Cell(s)—

- bacterial, cytoplasmic membrane, morphology and nature, 31.
- living, and radiation, 648.
- proliferations, camphor causing in onion roots, 183.

## Cellulose—

- bacterial culture decomposing, characteristics, 31.

## Cellulose—Continued

- bacterial decomposition, carbon dioxide essential factor, 483.
- content of *Sphagnum*, nature, 645.
- fabrics, flow properties of cuprammonium dispersions, fluidity calculations, 138.
- hydrolysis, method, 21.
- Micromonospora propionici* decomposing, 31.
- of bacterial and animal origin, fibrillar structure, 647.
- saccharification, quantitative method, 162.
- termites decomposing, mechanism, 31.
- Cellulosic materials, effects of temperature and humidity, 284.
- Centipedes from Georgia, 351.
- Centrifuge tube agitator, construction and operation, 149.
- Cephaleuros*, ascomycetous parasite, 336.
- Cerambycid beetles—
  - in Ohio, identification, 831.
  - of *Stenosphenus* in America north of Mexico, synopsis, 221.
- Cercopidae, spittlebugs of Missouri, 221.
- Cercospora oryzae*, new race, 334.
- Cereal(s)—
  - amylase inhibitor, distribution and general properties, 612.
  - black bacteriosis, tyrosinase factor, 63.
  - cytology, II, 648.
  - diseases, 334.
  - fermentation liquors, 2, 3-butylene glycol recovery, 164.
  - greenbug in Uruguay, 688.
  - industries, applied entomology, 85.
  - packaged, shelf life, determination, 266.
  - products—
    - fats, oxidative deterioration, 266.
    - thiamine and riboflavin contents, combined determination, rapid method, 470.
    - thiamine content, determination, simplified colorimetric method, 471.
  - root ellworm, *Heterodera major* in North Wales, 670.
  - rust control by barberry destruction, 63.
  - seed-borne diseases, prevalence and control in Manitoba, 62.
  - sprouts, dietary substitute for fresh vegetables, 266.
  - vitamin-fortified, stability of thiamin-chloride, 431.
  - vitamin B<sup>2</sup> content and supplying human requirements, 428.
  - winter, gas change and frost hardening, 486.
  - Xanthomonas translucens*, parasitism, 62.
- Chaetomium* spp., differential isolation from mixed populations by hypochlorite solution, 336.
- Chafer, European, in lawns, control, N.Y. State and Cornell 300.
- Chagasia roseboomi*, anopheline from Ceará, Brazil, 228.
- Chalaropsis thielavioides*, cause of failure of bud and graft unions of rose, 218.

- Chalcid fly, six new genera, descriptions, Iowa 534.
- Charcoal kiln made of cinder-concrete blocks, Conn. [New Haven] 572.
- Chatia setosa*, n. gen. and n. sp., chigger from northwestern U.S., 700.
- Cheatgrass brome, competition, effects on wheatgrasses, 327.
- Cheese—  
bacteriophage studies, 537.
- Cheddar—  
curing, influence of temperature, 715.  
phosphatase test, 20.  
slowness control in making, 99.  
coloring by annatto, II, 557.  
fatty acids, volatile, determination, simplified extraction-distillation method, 774.  
making, balance of milk nutrients and their fate during ripening, 536.  
new, salt content, estimation, by mercurimetric method, 621.  
pricing problems, 730.  
quality and vitamin content, relation to corn and alfalfa silage, 241.
- Chemical compounds, colorless, adsorption analysis, technique, 155.
- Chemicals, feeding to plants and animals for pest control, 527.
- Chemistry—  
agricultural, research progress reports, U.S.D.A. 140, 141, 142, Ala. 143.  
organic, physical methods, II, volume 2, 762.  
organic syntheses, book, 1.  
statistical methods, 1.
- Chemotherapy of cecal coccidiosis of chickens, IV, 720.
- Cherry(ies)—  
culture in Missouri, Mo. 202.  
dehydration of Montmorency, Mich. 123.  
fruitfly problem in eastern Washington, 363.  
sand, leaf curl and pockets, control, 828.  
sour, yellows virus, expression, effects of temperature, 645.  
sweet, new varieties, Idaho 53.
- Chestnut trees, old Japanese, vigor and susceptibility to blight, effect of mineral nutrition, 681.
- Chick(s)—*see also* Chicken(s); Ducks; Fowl; Hens; Poultry; Pullets.  
absorption of cinchona alkaloids and relation to antimalarial activity, 248.  
allantois, regulation, 499.  
availability of cystine and methionine, influencing of autoclaving soybean-oil meal, 847.  
baby—  
sex identification by color in Brown Leghorns, 45.  
sex identification in "red" varieties, 45.  
toxicity of sodium chloride solution, 858.  
bacterial syndrome in epidemic pullorum disease, 106.  
blood, cellular elements, relation to crystalline vitamin B<sub>6</sub>, 234.
- Chick(s)—Continued  
cecal coccidiosis—  
effect of sulfaguanidine, Del. 585.  
treatment with sodium sulfamerazine, 251.  
cerebellar disorder nutritionally produced, not associated with E avitaminosis, 550.  
choline-like effect of dimethylaminoethanol in ration, 94.  
color sexing Rhode Island Reds and New Hampshires, wing-spot method, 326.  
diet, monomethylaminoethanol and dimethylaminoethanol, effects, 549.  
embryos—  
infection with nonpigmented forms of *Plasmodium gallinaceum*, 250.  
Leghorn and polydactylous, effect of local applications of colchicine, 653.  
strophosomy production by local applications of colchicine, 653.  
encephalomalacia, nutritional, 306.  
fattening potency of estrogen feeding, rapid assay method, 46.  
fed high corn diet, effect of nicotinic acid, 549.  
feeding sunflower seed meal, 235.  
feeding thiouracil, desiccated thyroid, and stilbestrol derivatives, effects, 499.  
feeding varying amounts of riboflavin, results, 548.  
goitrogenic effects of rape seed in, 46.  
growing—  
nutrition, calcium, phosphorus, and vitamin D interrelationships, 550.  
phosphorus sources, sodium acid phosphate, tri-calcium phosphate, and bonemeal, 551.  
utilization of food elements, X, Comparison of open-pollinated and hybrid corn, Nebr. 378.  
utilization of food elements, XI, comparison of ground wheat and ground rye, Nebr. 547.  
growth response to methionine in rations, 94.  
immunizing exposure to cecal coccidiosis, use of chemotherapy, 720.  
liver, formation of folic acid, 616.  
liver lipids, effect of vitamin K deficiency, 720.  
newly hatched, pantothenic acid content, relation to content of eggs, 378.  
nicotinic acid requirement, influence of gelatine and tryptophan, 549.  
nutritional value of yeast protein, 591.  
ovarian effects of FSII and LH, 189.  
perosis caused by feeding high levels of thiouracil, 567.  
pituitary-gonadotropin response, 189.  
pregnant-mare serum response, 189.  
pullorum disease—  
control, 106.  
diet effects on epidemic, 106.  
treatment by sulfamerazine, 568.  
whole-blood test, 106.

## Chick(s)—Continued

- purified rations, activity of synthetic folic acid, 549.
  - pyridoxine requirement, 94.
  - rations, shark meal as protein supplement, 707.
  - sodium chloride ingestion, excessive, effect, 105.
  - starter ration—
    - supplements, calcite grit and granite grit, 551.
    - vegetable protein concentrates alone and with supplements, 93.
  - sulfonamide toxicity, evaluation, 106.
  - thyroid gland, effect of feeding thiouracil, 234.
  - tongue deformity, amino acid-deficiency role, 105.
  - unabsorbed yolk in body cavity, 551.
- Chicken(s)—*see also* Chick(s); Cockerels; Fowl; Hens, Poultry.
- blood, inoculation with Japanese B encephalitis virus, 367.
  - body louse, control by DDT, 88.
  - body measurements, relation to breast meat and live and dressed grades, 709.
  - breeding for increase of life span, Va. 710.
  - cecal coccidiosis—
    - chemotherapy, IV, 720.
    - established infections, use of drugs, 251.
    - experimental, sulfamerazine therapy, 398.
  - cannibalism, 251.
  - coccidiosis infection, experimental, effect of aryl arsonic acids, 567.
  - feeding meat and bone meal, 397.
  - growing, diet, choline content, toxicity, 858.
  - growing, feed utilization, relation to shank length, 707.
  - growing, on range and pasturage, new ration, Ohio 847.
  - immunity to *Plasmodium* spp., 250.
  - in vitro opsonic tests with *Plasmodium* spp., 250.
  - inbreds, development and use, 498.
  - infection with *Eimeria tenella*, effect of sulfaguanidine, 397.
  - infected with *Eimeria tenella*, toxicity of cecal cores, 387.
  - laying, calcium sources during hot weather, 551.
  - lymphoid tumor, immunization against, III, attenuation by heat, drying, and chemicals, 566.
  - malaria, parasitemia, increase following X-irradiation, 249.
  - meat type score, relation of edible percentage of meat, Mich. 380.
  - mite, encephalitis virus (St. Louis) congenital, 101.
  - osteopetrosis, production by filterable agent, 396.
  - pancreas, vitamin B<sub>6</sub> conjugase, 614.
  - poisoning by ANTU, 854.

## Chicken(s)—Continued

- precipitin production, II, in vitro rise of interfacial titers and precipitin formation, 566.
  - prophylactic vaccination against infectious laryngotracheitis, 252.
  - rations, corn-and-cob meal versus ground shelled corn, 847.
  - rumpleness, insulin-induced, II, III, 802.
  - tumors, lymphoid, production by filterable agent, 396.
- Chickpea, heterochromatic attraction and secondary association, 619.
- Chigger(s)—
  - culturing, 544.
  - mite, *Eutrombicula batatas*, habits and life history, 544.
  - new genus and species, *Ohattia setosa*, from northwestern U. S., 700.
- Children—
  - nutrition and chemical growth, II, original data, 274.
  - preschool—
    - calcium metabolism, 595.
    - citrate metabolism, 129.
    - food intake, factors influencing, 274.
  - school, diet, relation to tooth and bone structure in Florida, Fla. 886.
- Chile—
  - agricultural policy, U.S.D.A. 263.
  - carotene and ascorbic acid content, effects of canning and drying, N.Mex. 889.
  - citrus industry, U.S.D.A. 507.
- China—
  - plant hunting, history of botanical exploration, 637.
  - powdery mildew fungi, taxonomy, 209.
- Chinch bug, dust barrier tests, 77.
- Chinese gallnuts, general study, 57.
- Chloramine, bactericidal values, comparison with chlorine, 100.
- Chloride, effect on pecan and other native Oklahoma trees, Okla. 204.
- Chlorine, ovicidal value for *Aedes aegypti* eggs, 368.
- Chlorochroa sayi*—*see also* Say stinkbug.
- damage to sugar beets grown for seed, 834.
- Chloronitrobenzene, control of club-root, potato scab, clover stemrot, and brown root-rot of tomato, 676.
- Chlorophyll,—
  - content of—
    - plants, determination, 154.
    - summer squashes, 277.
  - rapid determination, apparatus, 298.
- Chloropidae, Iowa species, list, 534.
- Chloroplasts, frozen, dried, and homogenized, illuminated suspensions, oxygen evolution, 646.
- Chlorosis—
  - high-lime, relation to ferrous and ferric iron, 788.
  - in citrus leaves, control 828.
  - lime, in fruit trees, catalase variations in, 73.
  - lime-induced in Idaho plants, Idaho 58.

- Cholesterol, separation from degrass, 156.
- Choline—  
 analogs, utilization by cholineless mutants of *Neurospora*, 422.  
 content of—  
   dairy products, microbiological assay, 20.  
   diet of growing chickens, toxicity, 858.  
   wheat, oats, barley, flax, soybeans, 273.  
 deficiency, fatty liver, effect of chain length of fatty acids, 129.  
 excessive ingestion, effect on amount in tissues and urine of dogs and sheep, 128.  
 excretion from human body, effect of choline intake and environmental temperature, 422.  
 requirements of hens, 707.
- Choline-like effect of dimethylaminoethanol in chick rations, 94.
- Chorionic gonadotropin, effects on cystic ovaries in cow, 392.
- Chortolcetes terminifera*—see Locust, Australian plague.
- Christmas trees, species and culture comparisons, Ala. 57.
- Chromates in animal nutrition, 388.
- Chromium oxide-copper catalyst, preparation and reclamation, 146.
- Chromosome(s)—  
 number in chickpeas, 649.  
 numerous, counting technique, 494.  
 of cultivated plants, atlas, book, 648.
- Chrysanthemum aphid, wing production, genetic mechanism, environmental conditions affecting, 654.
- Chrysopa dorsalis*, biological notes, 86.
- Chrysophyllum* spp. of South America, 638.
- Chufas, uses and cultivation, Fla. 193.
- Chytrids, Brazilian—  
 VIII, parasites of rotifers and nematodes, 637.  
 IX, species of *Rhizophyidium*, 637.
- Cicada, 17-year, notes for 1945, 686.
- Cicadellidae of America north of Mexico, check list, Ohio 534.
- Cicer arietinum*, secondary association and heterochromatic attraction, 649.
- Cillochorella bambusarum* n. sp., cause of leaf spot of bamboo, and description, 679.
- Cimex lectularius*—see Bed bugs.
- Cinchona—  
 alkaloids, absorption in chick, and relation to antimalarial activity, 248.  
*officialis*, tests for Colombian Andes, 55.  
 Peruvian, alkaloids, distribution in bark, U.S.D.A. 148.  
 tests for Puerto Rican culture, U.S.D.A. 55.
- Citellus mexicanus*, ground squirrel, 683.
- Citrate metabolism, of preschool children, 129.
- Citric acid, assay in fermentation media and biological materials, 14.
- Citri vir pertinaciae*, virus of stubborn disease of citrus, 828.
- Citronella oil production in Guatemala, U.S.D.A. 667.
- Citrus—see also specific kinds.  
 fruits—  
   processing and marketing, readjustments, U.S.D.A. 870.  
   production, disposition, value and utilization of sales, 1909-44, U.S.D.A. 403.  
   rots caused by *Penicillium*, 217.  
   storage physiology, 666.  
   surface and volume determinations, tables, 53.  
   tolerance to methyl bromide as fumigant, Calif. 538.  
 ganoderma root rot, 679.  
 harvest wages, Los Angeles area, April-June 1945, U.S.D.A. 406.  
 industry of Chile, U.S.D.A. 507.  
 industry of Florida, Fla. 332.  
 insects, control by DDT, 225.
- Juices—  
 deterioration in storage, causes, 125.  
 fresh, ascorbic acid and flavor retention, 138.
- Leaves—  
 and rootlets, composition, influence of rootstock, 332.  
 chlorosis, control, 828.  
 petroleum oil spray deposits, determination, 305.
- Platypus compositus* attacking, 77.  
 psoriasis, additional information, 217.  
 relations of 10 elements and deficiencies in Calif., 346.  
 stubborn disease, virosis, symptoms, 828.  
 trees, mineral nutrient deficiencies in California, causes, 217, 346.  
 trees, rootlet rot, relation to nematodes, 679.
- tristeza disease—  
 identification by iodine test, 679.  
 relation to nematodes, 679.  
 volatile oils, assay apparatus, 10.
- Clays—  
 bonding action, II, dry molding sands, 861.  
 colloidal cultures, clay preparation and use as plant growth medium, 782.  
 minerals, soil-structure role, 169.
- Cleaning solvents, compositions and trade names, 140.
- Clear Lake gnat, light-trap studies, 534.
- Click-beetles, birds eating in Utah, 77.
- Climate—  
 and insect life, 169.  
 changing, 629.
- crop-production factors, 23.  
 effect on grapes in Michigan, 1945, 311.  
 of—  
   Arizona, 629.  
   China, effect on agriculture past and present, 23.  
   northwestern Canada, 23.  
   Scotland, problems, 23.  
   Texas, 629.

## Climate—Continued

prairie, trees, injury, death, and recovery, 167.

## Climatology—

agricultural, analogs in Ukraine and Norway vs. U.S.A., U.S.D.A. 168.

applications to building construction and agriculture, 630.

use of punched cards, 629.

world, treatise for advanced students, 474.

*Clostridium*—

*acetobutylicum*, riboflavin synthesis influence of iron inactivation by 2, 2'-bipyridine, 31.

*botulinum*—

incidence and distribution in Illinois soils, 272.

occurrence in soil samples, 25.

type C, cause of duck disease at Tulare Lake, 253.

infection in range animals, 717.

*tetani*, occurrence in soil samples, 25.

Clothes moths, control by DDT, thermal aerosol fogs in wool storage warehouse, 697.

## Clothing—

make-overs, new ideas, 285.

research progress reports, U.S.D.A. 142.

tailoring techniques for woman's suit, U.S.D.A. 139.

Clouded sulphur (butterfly), migrations in central U.S.A., 80.

Clouds, lower, comparison of bases with condensation levels, 23.

Clove oil, imitation, effectiveness in spicing pickles, 267.

## Clover—

alsike, seed production, honeybee role, Mich. 89.

and nodule bacteria, symbiosis, genetic factors, 651.

nodule bacteria, variation within strains in size of nodule and effectivity of symbiosis, 638.

root nodule bacteria isolated from, host specificity, 316.

rot in Britain, 337.

stemrot, control by chlornitrobenzene, 676.

## white—

seed production, honeybee role, Mich. 89.

self-compatibility factor and relation to breeding methods, 186.

virossis-like genetic disease, 39.

yield increase by manuring, La. 193.

Clubroot of crucifers, control by chlornitrobenzene, 676.

Coal, applications to Utah soils, results, 739.

Coating material, new synthetic, Norelac, 466.

## Cobalt—

deficiency disease of livestock, in Australia, 169.

efficacy in combating deficiency diseases of cattle and sheep in Norway, 563.

## Cobalt—Continued

feeding for prevention of "pining" in Cornwall and Devon, 704.

in biological materials, determination with nitrosocresol, 151.

soil deficiency in Australia, 169.

## Coccidiosis—

## cecal—

effect of sulfaguanidine, Del. 585.

of chickens, chemotherapy, IV, 720.

of chickens, effect of aryl arsonic acids, 567.

of chickens, sulfamerazine therapy, 398.

of chickens, use of drugs, 251.

treatment by sodium sulfamerazine, 251.

intestinal, in commercial rabbitries, control by phthalylsulfathiazole, 387.

*Coccus hesperidum*—see Soft scale.

*Cochliomyia americana*, population in Arizona, 369.

Cockerels, breeding, selection by sisters' performance, 44.

## Cockroach(es)—

arsenite-injected, concentration-survival time curves, analysis, 539.

site of action of DDT, 227.

Cocks, old, meat quality, effect of estrogens, 709.

Cocoa, effect on utilization of dietary calcium, 594.

## Coconut—

diseases of leaves, crown, and stem, 74.

palm, disease in Jamaica, 519.

## Cod-liver oil—

effect on flavors and vitamin C content of milk, 554.

U.S.P. reference vs. beta-carotene, standards in vitamin A assays, 470.

Codecarboxylase—see also Pyridoxal phosphate.

assay system, 179.

comparison of natural and synthetic, 179.

conversion of vitamin B<sub>6</sub> group, 769.

## Codling moth—

attacking pear and apple, life history differences, 693.

control with DDT—

in Colorado, Colo. 693.

in Virginia, 356.

in western New York, N.Y. State and Cornell 362.

in western New York in 1945, 694.

precautions, 694.

control with lead arsenate, influence of ingredients and dosage, Va. 694.

from walnuts, apples, and pears, emergence time, longevity, and oviposition, Calif. 536.

hibernating larvae, susceptibility to low temperature, and bound-water content, U.S.D.A. 536.

in Oklahoma orchards, control, 537.

larval control by—

4,6-dinitro-o-cresol tests on overwintering larvae, 77.

- Codling moth—Continued  
larval control by—continued  
4,6-dinitro-o-cresol, toxicity persistence on tree trunks, 77.  
N-substituted 2,4-dinitroanilines on larvae, 77.  
N-substituted *p*-toluenesulfonamides, 77.  
 $\alpha$ -trichloromethyl-substituted benzenes, 77.
- Coffee—  
Dominican, U.S.D.A. 507.  
plant, nitrate utilization under different sunlight intensities, U.S.D.A. 203.  
pulp, feed value for livestock, 372.  
soil, saving in Puerto Rico, U.S.D.A. 666.
- Colchicine—  
effect on development and maturing of polyspermic corn, 39.  
in combination with X-ray, effect on plant tissue, 207.  
review of research of five years, 185.
- Colias*—  
*philodice eurytheme*—see Alfalfa caterpillar.  
*philodice philodice*—see Clouded sulphur. spp., migrations in central U.S.A., 80.
- Coliform bacteria, differential tests, influence of incubation temperatures, 634.
- Colleges, land-grant, workers in subjects pertaining to agriculture, 1945-46, U.S.D.A. 875.
- Collectotrichum*—  
*circinans*, toxicity to of carboxylic acids, phenols, and crucifer extracts, effect of pH, 821.  
*Witt* in lily bulbs, eradication action of fungicide, 347.
- Colloids, classes, systems representative, electro-viscosity data, 467.
- Colloidal clay cultures, clay preparation and use as plant growth medium, 782.
- Colombia—  
agricultural prices and wages, 724.  
*Haemagogus* mosquitoes, 228.
- Color—  
science, selected references, 433.  
standards for McIntosh apple leaves, N.Y. State and Cornell 816.
- Color-inhibiting factor in onion, relation to smudge resistance, U.S.D.A. 216.
- Colorado potato beetle—  
adults attacking their own eggs, 359.  
attractant to potato leaves, purification, first attempts, 225.  
burrowing, contact, thigmotaxis and sensory localization, 225.  
larvae, attack on tubers, 225.
- Colorado A. and M. wool laboratory, capacity increase, 285.
- Colorado College, notes, 445, 911.
- Colorado Farm Bulletin—  
September-October, November-December, 1945, Colo. 287.

and postwar relief, 407.  
canning—  
1943-44, U.S.D.A. 584.  
status, 1943-44, 584.

## Cooperative(s)—Continued

- extension work in agriculture and home economics, 1945, report, U.S.D.A. 734.
- farmers'—
  - membership relations, Okla. 264.
  - organizing, U.S.D.A. 118.
  - regional purchasing associations, research practices and problems, U.S. D.A. 408.
  - thirteen, operations and management in north Georgia, 1944, Ga. 871.
- movement and present-day problems, rehabilitation and reconstruction, 407.
- organizations serving farmers in five Ohio counties, relationships, Ohio 871.
- petroleum, affiliated with Southern States Cooperative, Inc., delivery efficiency, U.S.D.A. 408.

Cooperative Rubber Research Station, Costa Rica, U.S.D.A. 204.

## Copper—

- distribution and content of blowflies, 541.
- effect on linoleic acid autoxidation, N.Y. State 147.
- fungicidal action, mechanism, 62.
- fungicides—
  - control of potato blight, 672.
  - cryolite compatibility, 80.
- in plants, determination by ashing procedures, 152.
- ions, translocation in plants, 643.
- naphthenates, value as wood preservatives, 519.
- 8-quinolinolate, promising fungicide, 670.
- reduction method, for sugar assays, 15.
- rot-proofers, treatment of cotton fabric, effect of weathering, 604.
- sulphate and Black Leaf 40—*see* Cunic.
- toxicity to *Bugula neritina*, 358.

Copper-chromium oxide catalyst, preparation and reclamation, 146.

*Coprinus* spp., growth at various H-ion concentrations, preliminary contribution, 487.

Coprophyagy, self-selection by rats, source of vitamin B complex, 279.

*Corchorus* spp.—*see* Jute.

Cordulidae, distribution and seasonal abundance in Indiana, 80.

Cork oak, bibliography, U.S.D.A. 333.

Corn—*see also* Maize; *Zea mays*.

## borer—

- European—*see* European corn borer.
- observations in 1943, 834.
- carotene content of plant, 193.
- chemical composition of diploid vs. tetraploid, 6.
- colchicine effects on development and maturing of polyspermic, 39.
- convergent improvement and backcrossing, Minn. 494.
- deterioration in storage, relation to molds, review, 337.
- development in U. S., Mexico, and Central America at different latitudes and altitudes, 502.

## Corn—Continued

- diseases, 334.
- double crosses, predicted performance vs. predicted and actual performance in later years, 194.
- ear, drying, preliminary report, Nebr. 255.
- ear rot due to *Phylospora zeae*, 65.
- earworm, observations in 1943, 834.
- feeding to chicks, effect of nicotinic acid, 549.
- green feed supplement for livestock, 90.
- Helminthosporium turcicum* leaf blight, 824.
- hybrids—
  - and varieties, tests in Mississippi, 1945, 806.
- performance tests, 1945, N.C. 192.
- tests in Illinois, 1945, Ill. 502.
- inbred lines, early testing, 806.
- kernels, immature, 3-indoleacetic acid isolation, 35.
- meal—
  - and grits, facts and receipts, 588.
  - crude fiber content, determination by biochemical method, 620.
- white, shortage effects, 591.
- milling, wet, effect of sulfuric acid steep, 451.
- nicotinic acid-deficiency role, 135.
- nitrogen—
  - fertilizer, placement, U.S.D.A. 633.
  - metabolism, influence of ammonium nutrition, 794.
- oil, fatty acids, 295.
- open-pollinated and hybrid, comparison for growing chicks, Nebr. 378.
- performance tests of varieties and hybrids (1945), Iowa 195, Okla. 195, S.Dak. 195.
- phymatotrichum root rot, as influenced by carbohydrates and root microfloras, 65.
- plants, distribution in field, 806.
- potash deficiency in growing, correcting, Tenn. 47.
- rootworms, general study in Nebraska, Nebr. 83.
- seed—
  - drying temperatures for, factors determining, Ind. 195.
  - storage insects, control 836.
  - treatment by slurry method, 671.
  - treatment in Oklahoma, Okla. 210.
- shucks to beef, N.C. 547.
- smut fungus, sporidial fusion, U.S.D.A. 210.
- soil tests in Nebraska, 481.
- starch content, determination improvements, 472.
- steep liquor, role in production of penicillin, 612.
- sweet—
  - combining ability of successive generations of inbred, Conn. [New Haven] 38.
  - inbreeding by nonindividual pedigree method, Conn. [New Haven] 39.

- Corn—Continued  
 sweet—continued  
   Japanese beetle abundance and injury, N.Y. State 361.  
   "long husk" sterility, Conn. [New Haven] 186.  
   seed treatments, N.J. 216.  
   suckering trials in California, Calif. 815.  
   U.S.D.A.—34, variety for Puerto Rico, U.S.D.A. 505.  
 waxy vs. nonwaxy for dry-lot fattening of pigs, 92.  
 whole kernel, raw and canned, maturity measurement by succulometer 770.  
 yields—  
   effects of lime, fertilizer, and preceding legumes, on Sango silt loam, Tenn. 803.  
   improved by legumes, La. 194.  
   relation to nutrient balance, shown by leaf analysis, 658.  
 Corn-and-cob meal versus ground shelled corn in rations for chickens, 847.  
 Corncobs to beef, N.C. 547.  
 Cornea—  
   lesions, healing, effects of light, trauma, riboflavin, and ariboflavinosis, 600.  
   vascularity, production, effects of light, trauma, riboflavin, and ariboflavinosis, 600.  
 Corneal vascularization in rats on tryptophan-deficient diet, 737.  
 Cornell Station—  
   notes, 607.  
   report, 1945, 908.  
 Cornell University, notes, 446, 607.  
 Cornstalk rots in Virginia (1945), U.S.D.A. 58.  
*Coronimya*, review with key to species and new taxonomy, 687.  
*Corynebacterium*—  
   *equi*, foal infection, 100.  
   forms in bovine infectious pyelonephritis, 103.  
   *ovis*, abscesses in goats caused by, 104.  
   *pyogenes*, survival in discharges from udder and uterus of cow, 391.  
*Cosmia venosa* n. g. and n. sp., description, 534.  
 Cotton—  
   acreage and prices in Tennessee, Tenn. 111.  
   aphid, outbreaks and control, Ark. 834.  
   aphid-resistance, test, 81.  
   carbohydrate exchange, influence of aphids, 359.  
   crop insurance in Tennessee and United States, Tenn. 583.  
   experiments, error, source in environmental modification of fiber properties, U.S.D.A. 806.  
   fabrics—  
   containing copper rot-proofers, effect of weathering, 604.  
   flameproofing for outer garments, 434.  
 Cotton—Continued  
   fabrics—continued  
   manufactured in Alabama, comparison with similar fabrics in ready-to-wear garments, 749.  
   rotproofed, soil burial test, 900.  
   treated, resistance to attack by termites and microorganisms, 604.  
   used for glass curtains, Ohio 750.  
   utilization, styles study in Alabama, 749.  
   farm production, disposition, and value, 1928-44, by States, U.S.D.A. 264.  
   farming, U.S.D.A. 261.  
   farms, labor changes in Arkansas, 1939-44, 866.  
   fiber—  
   isolation of *l*-malic acid and citric acid from, 295.  
   raw, organic acid content, 295.  
   properties, environmental modification, source of error in experiments, U.S.D.A. 806.  
   wax determination by alcohol extraction method, 155.  
   fruiting and shedding, relation to light and other limiting factors, Tex. 659.  
   galloping wilt, physiology, 338.  
   gin operation, economics of, Miss. 115.  
   ginning, effects of farm mechanized production, 572.  
   heat-resistance of leaves on saline soils, 36.  
   insect pests, status and control in Lower River districts of Nyasaland, 535.  
   insects, control by benzene hexachloride, 535.  
   nitrogen for, liquid and solid sources, Miss. 177.  
   phymatotrichum root rot, influence of carbohydrates and root microfloras, 65.  
   plant, foliar hydration, VII, size factor, 644.  
 rat—  
   dental caries, III, effects of dietary carbohydrates, 420.  
   dental caries, IV, effects of fluorine, 420.  
   dental caries, V, influence of strain variation, 421.  
   parasite, *Atricholaelaps sigmodoni* n. sp. with notes on *Atricholaelaps* and *Ichnolaelaps*, 701.  
   studies, 351.  
   root bark, electrodialyzable constituents, identity, 466.  
   rotated with peanuts, potash and lime requirements, 807.  
   rust, nutritional factors influencing, 196.  
   salt-resistance, as influenced by day length, 185.  
   thread, sewing, selection, Ohio 751.  
   varieties—  
   in hill section agronomic data (1941-45), Miss. 196.  
   in hill section, comparisons (1945), Miss. 196.

## Cotton—Continued

- varieties—continued
- performance tests (1945), N.C. 192.
- tests in Georgia, 1942-45, Ga. 502.
- yarns, carded and combed, knitted fabrics, physical properties, 433.
- yields, effect of—
- crop rotation, Miss. 654.
- plowing under hairy vetch, 196.

## Cottonseed—

- extractable gossypol in, assay, spectrophotometric method, 14.
- farm production, disposition, and value, 1928-44, by States, U.S.D.A. 264.
- longevity, influence of climate and seed treatments, 196.
- marketing in Louisiana, La. 584.
- meal and meats, gossypol content, estimation, 776.
- meal, extractable, gossypol in, assay, spectrophotometric method, 14.

## oil—

- carotene content, stability, effect of antioxidants, 465.
- fractional crystallization from solvents, tocopherol concentrates, 458.
- gossypol content, estimation by spectrophotometric method, 776.
- hydrogenated, molecular distillation, with characteristics of distilled fraction, 458.
- hydrogenated, stability, effect of metallic salts, 457.
- oxidation, red quinoid substance developed,  $\gamma$ -tocopherol as precursor, 459.
- solvent extraction, techniques, 147.
- thermal properties, 455.
- pigments, four, 452.
- proteins, color improvement, 764.

Cover crops, influence on wireworm injury to tobacco, Conn. [New Haven] 691.

## Cows—

- acetonuria, use of chloral hydrate and sodium bicarbonate, intoxications, 716.
- artificial insemination, techniques, 42.
- blood, contents under various physiological conditions, 383.
- breeds, influence on feed cost of milk production, 552.
- cobalt-deficiency disease, in Australia, 169.
- colostrum, vitamin contents, 98.
- cystic ovaries, effects of chorionic gonadotropin, 392.

## dairy—

- Cornell, comparative size, N.Y. [Cornell] 711.
- ketosis, vitamin A therapy, 560.
- live weight, variations, Vt. 850.
- live weight versus metabolic body size, 711.
- long life, advantages, 851.
- potato silage, making and feed value, U.S.D.A. 381.
- reproduction and lactation, references to literature of 1940-43, 552.

## Cows—Continued

## dairy—continued

- respiration rate, body temperature, and pulse rate, factors influencing, 850.
  - sterility, genes for, 187.
  - dystocia from uterine torsion, instrument for relieving, 100.
  - feeding cod-liver oil, effect on flavors and vitamin C content of milk, 554.
  - feeding iodinated casein on farms in England and Wales, 712.
  - heifer, ketonemia in fetus of, 100.
  - infected with *Brucella abortus*, changes of serum phosphatase level, 390.
  - mammary gland, penicillin (infused) effects, 102.
  - manure feeding, effect on egg production and hatchability, 95.
  - milk—
  - concentrates, wild yellow mustard seed and fanweed seed, Mont. 849.
  - feeds, comparison of molasses-grass with barley-grass silage, N.J. 236.
  - feeds, comparison of molasses-timothy with barley-timothy silage, N.J. 236.
  - grading as calves for mammary development, 238.
  - grazing performance, effect of warm weather, 380.
  - summer feeding on pasture, Ohio 381.
  - winter feeding of simple vs. complex grain, Ohio 98.
  - normal, isolation of diphtheroids, 717.
  - prepartum diet, effect on vitamin A reserves of newborn offspring, 382.
  - pyometra following retained fetal membranes, effects of stilbestrol, 392.
  - sterility, research progress reports, U.S.D.A. 99.
  - udder and uterus, discharges, survival of *Corynebacterium pyogenes*, 391.
  - udder, invasion by heat-resistant bacteria from unclean milking machine, 831.
- Coyotes, decoying, method, 682.
- Cranberry (ies)—
- fruitworm infestation of blueberries, control, 836.
  - insects and weather affecting, report, 836.
  - storage investigations, Mass. 401.
- Crane-flies, undescribed species from western U.S. and Canada, 687.
- Cream, frozen, physical stability, contributing factors, 385.
- Credit—
- forest, 1930-45, U.S.D.A. 206.
  - tailored, for land improvement, 724.
  - tobacco farms in Puerto Rico, 1939-40, P.R.U. 727.
- Orepi* spp. and interspecific hybrids, cytogenetic study, karotype evolution, 649.
- Crioceris illi*, damage in Britain, 696.
- Cronartium*—
- justiforme*, damage to slash pine, Miss. 219.
  - occidentale*, differentiation from *C. ribicola* in telial stage U.S.D.A. 58.

- Cronartium*—Continued  
*ribicola*, differentiation from *C. occidentale* in telial stage U.S.D.A. 58.
- Crops—  
 agricultural, research progress reports U.S.D.A., 140.  
 and soils of Oklahoma, report, 1946, Okla. 753.  
 climatic factors in production, 23.  
 diseases, outstanding, and uses of fungicides in U.S., 508.  
 ecology, analogs in Ukraine and Norway vs. U.S.A., U.S.D.A. 168.  
 farm, research in Mississippi, Miss. 804.  
 fertilizer effects on yields and composition, 173.  
 field, diseases, 335.  
 garden, diseases in Georgia (1945), U.S.D.A. 58.  
 garden, seed treatments in western Washington, Wash. 215.  
 nickel deficiency, 509.  
 on acid soils, manganese toxicity, 509.  
 residues, soil-temperature effects, 27.  
 trace element deficiencies, multiple, 509.  
 variety comparisons, agrobiologic test for normality in, 173.  
 yield-depression effects of fertilizers, 27.  
 yields and fertilizer use, bibliography, 790.  
 yields, effect of sources of nitrogen, 786.
- Cropland use in war and peace, U.S.D.A. 581.
- Crops and Markets—  
 January 1946, U.S.D.A. 264.  
 April 1946, U.S.D.A. 585.
- Orotalaria spectabilis*, cause of poisoning in Louisiana livestock, 241.
- Crucibles, Selas filtering, reverse-flow washing, 10.
- Crucifer extracts, toxicity to *Colletotrichum circinans*, effect of pH, 821.
- Cryolite—  
 copper-fungicide compatibility with, 80.  
 dust—  
 control of sugarcane borer, 360.  
 diluent, alkaline, 352.
- Cryptostegia*—  
*grandiflora*—  
 latex flow, influence of time of day, 491.  
 morphology and anatomy, U.S.D.A. 796.  
 rubber from leaf latex of, 162.  
 non-latex rubber content, 796.
- Cryptotermes brevis*—see Polilla.
- Cuba, insect and other arthropod pests, catalog, 532.
- Cuban-laurel thrips, control on *Ficus benjamina*, 836.
- Cucumber—  
 anthracnose control, 334, 336.  
 anthracnose, control by Fermate, 827.  
 downy mildew resistant, development, S.C. 815.  
 hybrid, seed, production by honeybee pollination, 370.
- Cucurbits—  
 aphid-resistance, test, 81.  
 downy mildew resistance, test, 81.  
 pickleworm, life history and control, 536.
- Culex*—  
 males, identification under low magnification, 540.  
*quinquefasciatus*—see Southern house mosquito.
- Culture—  
 chamber, constant-temperature water bath, 318.  
 media, agar, gas bubbles developing in, 30.  
 media, stale, effect on fungi and bacteria, 32.
- Cunic, control of gastrointestinal helminthiasis in sheep, 564.
- Cuproammonium, cellulose dispersions, fluidity values, calculation, 138.
- Curly top of beans, relation to beet leafhopper selection of bean varieties, 833.
- Currants, black, vitamin C content, as influenced by cold processing, 137.
- Current Farm Economics—  
 February 1946, Okla. 264.  
 April 1946, Okla. 402.  
 June-August 1946, Okla. 863.
- Curtis, George Washington, and Frank Arthur Gulley, two early agricultural teachers in Texas, 587.
- Cuttings—  
 root formation, leaf role, 35.  
 rooting of growth-substance-treated, 49.
- Cyamopsis tetragonolobus*—See Guar.
- Cyclones, three, in Mauritius in 1945, effects, 476.
- Cyperaceae, *Sclerotinia* spp. on, 33.
- Cyperus esculentus*, food and feed uses and general information, Fla. 192.
- Cysticercus bovis*, thermal death point, 387.
- Cystine content of plant and animal material, determination by differential oxidation procedure, 773.
- Cytogene, mendelian segregation, phenomenon of dominance, 493.
- Cytology, animal, book, 41.
- 2, 4-D—see also 2, 4-Dichlorophenoxyacetic acid.  
 control of—  
 ragweed with care around crop plants, N.Y. State and Cornell 814.  
 weeds, N.J. 504.  
 weeds in canning peas, Mich. 49.  
 weeds in Colorado, 329.  
 weeds on sugarcane lands, U.S.D.A. 811.  
 weeds, period of effectiveness, 813.  
 effects on ragweed and certain woody plants, Mich. 664.
- D-D mixture for wireworm control, 82.
- DDT—  
 action in cockroach, site, 227.  
 action in flies, site, 530.  
 aerosol, non-volatile content, effect on house flies, 840.

## DDT—Continued

aerosols, efficacy against common malaria mosquito and housefly, 541.  
 airplane spraying—  
   for control of adult mosquitoes in open, unwooded areas, 303.  
   of rice fields for mosquito larvae, 87.  
 and derivatives, physical properties, 337.  
 and lead-arsenate-phenothiazine sprays, Pa. 531.  
 and related compounds, stability, 467.  
 bromine analogs, 466.  
 budbugs exposed to, effect of temperature, 227.  
 compatibility with insecticides, fungicides, and fertilizers, 223.  
 compounds, toxicity to houseflies, comparison with pyrethrum, 229.  
 control of—  
   adult mosquitoes, outdoors, applied with ground equipment, 368.  
   American dog tick, vector of Rocky Mountain spotted fever, preliminary tests, 701.  
   apple blossom insects, 225.  
   bugs causing deformed peaches, 537.  
   cauliflower worms on Long Island, 691.  
   chicken lice, 88.  
   codling moth in Colorado, Colo. 693.  
   codling moth in Virginia 356.  
   codling moth in western New York, N.Y. State and Cornell 362.  
   codling moth in western New York in 1945, 694.  
   filter fly in sewage, 697, 698.  
   fire ant, 696.  
   flies in dairy barns, 366.  
   flies in dairy barns, N.Y. State and Cornell 840.  
   Gulf Coast ticks on range cattle in Florida, 542.  
   hairy chinch bug, 833.  
   hide beetles, 837.  
   horn fly in Kansas, 542.  
   horn fly on range cattle in Florida, 542.  
   household and stored grain insects, 539.  
   immature squash bugs, 693.  
   insects affecting livestock, 839.  
   insects affecting man, 840.  
   insects in canning industry, 85.  
   insects, in dairy barns, 366.  
   insects in fishery industries, 85.  
   insects of livestock, poultry, household, garden, and fruits, Mo. 833.  
   mosquitoes, 366.  
   northern feather mite, *Liponyssus sylviarum*, 544.  
   onion thrips, Ohio, 361.  
   oriental fruit moth, comparison with Ryanex, 694.  
   oriental fruit moth on peaches, 695, 834.  
   potato aphids in New York, 690.  
   potato aphids in northeastern Maine, 690.  
   roaches, formula improved by "Lethane A-70", 697.

## DDT—Continued

control of—continued  
   sarcoptic mange, 387.  
   sheep tick, *Ixodes ricinus*, 701.  
   *Simulium* larvae, 88.  
 dehydrochlorination of substituted 2, 2-diphenyl-chloroethanes related to, kinetic study, 9.  
 determination, colorimetric method—  
   color test for related compounds, 305.  
   description, 304.  
 dispersion from fast aircraft, 79.  
 dust, control of anthracnose and leafhoppers on snap beans, Mich. 360.  
 dust, dosage tests on vegetable pests, 352.  
 effect on—  
   aster yellows, 337.  
   cabbage maggot of radish, 357.  
   cutaneous sensations in man, 685.  
   fish and wildlife, 530.  
   leaf hopper on head lettuce, 337.  
   potato insect pests, N. Dak. 211.  
   stem rust reaction of Khapli wheat, 342.  
   yeast fermentation, 223.  
 efficacy against scab mites on laboratory rabbits, 369.  
 emulsion, application to rice-field water for control of mosquitoes, 540.  
 eradication of swine louse *Haematopinus suis* by single treatment, 543.  
 excretion in man, clinical observations, 223.  
 fabrics impregnated with, effect on insects, 85.  
 in quick-breaking fuel-oil emulsions, 358.  
 in spray residues and insecticide mixtures, analysis, 778.  
 in technical and pure compounds, determination by total chlorine procedures, 778.  
 in veterinary medicine, 389.  
 inefficacy against—  
   apple mite, 225.  
   pea aphid, 692, 693.  
 insecticidal aerosols containing, accelerated aging test, 778.  
 insecticides, more research needed, N.Y. State and Cornell 358.  
 intelligent use in horticulture, 833.  
 kerosene solutions, penetration prevented by aluminum stearate, 79.  
 large-scale application by thermal aerosol fog generator, 684.  
 mosquitoes exposed to, effect of temperature, 227.  
 optical crystallographic properties of purified single isomer, 8.  
 pest control research, progress in cooperative project, 79.  
 potato insecticide in 1945, results in six States, summary, 689.  
 present status as insecticide, 529.  
 quantitative estimation in sample, 305.  
 removal from water supplies, 224.  
 residual sprays, use in home, 833.

## DDT—Continued

- residual-type sprays, effects of light, 529.
- residues on fruits and vegetables, Mich. 675.
- resistance of bedbugs, biological factors, 365.
- sensitivity, correlation with possession of chitinous cuticle, 529.
- significance in agriculture, 528.
- soil application, efficacy of protection of plants from black beetle, 531.
- spray, or dust deposits, quantitative estimation, 305.
- sprays and European red mite populations, 77.
- sym*-tetraphenylethane from related compounds and, 9.
- technical, chemical composition, 8.
- technical, determination of 1-trichloro-2, 2-bis (*p*-chlorophenyl) ethane in, 305.
- thermal aerosol fogs for clothes moths in wool storage warehouse, 697.
- threat to bees, N.C. 702.
- toxicity to—
  - animals, 529.
  - domestic and laboratory animals, 86.
  - man, 531.
- use—
  - against codling moth, precaution, 694.
  - against insect pests of soft fruits, 363.
  - as agricultural insecticide, trials, 1944–45, 357.
  - at farmstead, evaluation, Minn. 531.
  - for Murine typhus control in Southwest, 358.
  - in agriculture, 357.
  - in medicine, review, 854.
  - in Tulare County, 225.
  - value as agricultural insecticide, 223.

DDT-rotenone spray, control of cattle ticks in tropical regions, 543.

## Dairy—

- bacteriology, papers, abstracts, 713.
- cattle—*see* Cattle, dairy.
- farming, analysis, Putnam County, Georgia, 1944, Ga. 261.
- farms, management, Putnam County, Georgia, 1944, Ga. 261.
- herds, brucellosis control and its relation to milk supply, 716.
- herd, Calhoun, high average production, La. 238.
- industry—
  - development and economics in Mississippi, Miss. 114.
  - quality control in, 121.
  - scientific advances, review of literature, 1945, 552.
  - sterilization methods, 99.
- products—
  - biotin content, microbiological assay, 20.
  - choline content, microbiological assay, 20.
  - marketing adjustments in Michigan, Mich. 115.

## Dairy—Continued

- products—continued
  - pasteurization, 239.
  - research progress reports, U.S.D.A. 97.
  - sterilization methods, 99.
- rations, grain mixtures, simple vs. complex, II, summer feeding milk cows on pasture, Ohio 381.
- rations, grain mixtures, simple vs. complex, III, IV, Ohio 849.
- Research Digest, 1946, La. 848.
- science, progress, review, Sec. A, physiology of dairy cattle, I, reproduction and lactation, 552.

Dairy Industry, Bureau of, report of Chief, 1945, U.S.D.A. 42, 140, 141.

## Dairying—

- insect control, 840.
- research progress reports, U.S.D.A. 97, 140, Ala. 143.

## Dandelion—

- control with 2, 4-D, Wyo. 505.
- Russian—*see also* Kok-saghyz; *Taraxacum kok-saghyz*.
- content in live roots, estimation, 184.
- latex-tube areas of roots and leaves, U.S.D.A. 493.

## Date, Deglet Noor—

- fruits, checking, relation to water deficit, U.S.D.A. 203.
- leaf elongation and fruit growth, relation to soil-moisture deficiency, U.S.D.A. 203.

Dates, composition, changes during growth and ripening, U.S.D.A. 204.

*Datura stramonium*, Duvel buried seed experiment, U.S.D.A. 201.

Deer, Columbian black-tailed, parasites, diseases, injuries, and anomalies in British Columbia, 682.

Degras, cholesterol separation from, 156.

Degreasing solvents, compositions and trade names, 140.

## Dehydration—

- control, peroxidase aids, quick test, 271.
- fruits, new methods, 270.
- kale, 270.
- small fruits, 123.

vegetables, varietal suitability, 122.

Dehydrators, farm, mechanical features, 110.

Dehydroascorbic acid, excretion in sweat and urine under different environmental conditions, 740.

7-Dehydrocholesterol (D3) antirachitic potency for growing pigs, 376.

Dehydrofreezing, new method of preserving food, 879.

Delaware Station report, 1945, Del. 900.

*Deleaster dichrous*, European staphylinid, occurrence in North America, 354.

Demand, intraseasonal, determination, 724.

Dendrochronology, researches, 779.

Denmark, plant diseases and pests, 670.

Densitometer for GR-S latices, description and use, 767.

*Dermanyssus gallinae*—*see* Chicken mite.

- Dermatological condition in animals, acid-ester remedy, 387.
- Dermatosis, filarial, of sheep, treatment with antimony compounds, 856.
- Derris—  
 combination with high-boiling-point tar acids, effectiveness against body lice, 543.  
 comparison, toxicological, with *Lonchocarpus*, 832.  
*elliptica*—  
   clones, evaluation, 798.  
   composition, effects of altitude and water supply, 794.  
   rotenone test applied to, 14.
- Desthiobiotin in biosynthesis of biotin, 615.
- d, l-Desthiobiotin, synthetic, biological activity, 134.
- Devils shoestring, rotenone-bearing, response to fertilizer applications, 807.
- Dewberries, summer care, Miss. 817.
- Dextran, from sucrose, enzymatic synthesis, 765.
- Dextri-maltose, nutritive value, determination by single-food choice method, 419.
- Dextrose—  
 assay by copper reduction method, 15.  
 nutritive value vs. sucrose, in rats, 136.  
 utilization, influence of thiamine in rats, 136.
- Diabrotica*—  
*duodecimpunctata*—see Southern corn root-worm.  
 spp., corn pests in Nebraska, 83.
- Diacetyl—  
 determination in tissue and bacterial filtrates, direct, method, 473.  
 production by betacocci in milk, effect of acidity, 554.
- Diamondback moth, rotenone-dust, effects, 80.
- Dichloroacetic acid, in food products, detection and assay, 16.
- 2, 4-Dichlorophenoxyacetic acid—see also 2, 4-D.  
 effect on germination and development of seedlings, 320.  
 effect on water relations, solid matter, and respiration of bean plants, 320.  
 feed containing, tolerance of farm animals to, 558.  
 stimulus, movement and relation to translocation of organic food materials, 320.  
 use for improvement of greenhouse tomatoes, Mich. 331.
- 1, 2-Dichloropropane-1, 3-dichloropropene mixture—see D-D mixture.
- Dictionary of fungi, 815.
- Dicystotellium discoideum*, morphogenic-movement rate, 38.
- Diesel gas engine, producer gas application to, 162.
- Dietary—  
 factors, guinea pig requirements, 138.  
 habits of Cornell University women, 885.  
 level of 100 families, 274.
- Diet(s)—  
 caloric value, Atwater system of calculation, 130.  
 improvement by use of wheat substitutes and green vegetables, Miss. 886.  
 of aircraft workers in southern California, I-IV, 418.  
 protein-free compounded with amino acids, proteins added, growth stimulating action, 591.  
 protein level, effect on vitamin A utilization by rats, 133.
- Digester, rotary, for wood saccharification, 22.
- Digestibility, apparent, coefficients, estimation by inert "reference-substance," 703.
- Difodotyrosine, formation of thyroxine from, effect of experimental conditions, 449.
- Dimethylaminoethanol—  
 choline relation to, 94.  
 in chick rations, 549.  
 choline-like effect, 94.
- Dimethylglyoxime-copper treatment for rot-proofing fabrics, 900.
- Dinitro compounds, toxic action on honey-bee, 702.
- 2, 4-Dinitroanilines, N-substituted, in codling moth larval control, 77.
- Dinitro-*o*-cresol, fungistatic activity, effect of pH, 207.
- 4, 6-Dinitro-*o*-cresol, for codling moth larvae control, 77.
- Dinoflagellate, new parasitic, from freshwater fish, 351.
- 2, 2-Diphenylchloroethanes, dehydrochlorination of substituted DDT-related, kinetic study, 9.
- Diphtheroids, isolation from apparently normal cows, 717.
- Diplodia—  
 rot of onions, 344.  
*theobromae*, cause of die-back of guayule, 680.  
*zeae*, spore production and germination in culture, 65.
- Directory of agricultural periodicals, societies, experiment stations, and schools in Latin America, 911.
- Disaccharide, enzymically synthesized crystalline, isolation and structure, 4.
- Diseases—see under Animal(s); Fruit(s); Plant(s); Vegetable(s); also *specific hosts and names*.
- Disinfectants for—  
 greenhouse soils, 61.  
 institutional equipment, 126.
- Disinfection, by phenol, temperature coefficient of reaction by new technique, 101.
- Disodium ethylene bisdithiocarbamate—see Dithane.
- Distemper, canine, control by distemperoid virus, 395.
- Distillers' byproducts—  
 in dry calf starters with limited quantities of milk, Nebr. 237.

- Distillers' byproducts—Continued  
in poultry breeding diets, 94.  
nutritive value as source of protein, 231.
- Dithane—  
control of Mexican bean beetle, 81.  
use on soil for control of insect pests of plants, 352.
- Ditylenchus destructor*, 1945 potato-rot nematode in Prince Edward Island, 212.
- Doassansia hygrophilae* n. sp., nuclear cycle and life history, 509.
- Dodder, stem tips, excised, cultivation in vitro, 488.
- Dodders, reaction to stems of other dodders and to their own stems, 336.
- Dog(s)—  
absorption and excretion of calcium pantothenate, 601.  
anomalous posterior vena cava, 387.  
blood plasma, determination of free leucine, isoleucine, valine, and threonine, 618.  
Collie breeds, differences, 44.  
distemper, control by distemperoid virus, 395.  
English Setter, bicolor gene in, genetic analysis, 44.  
enteric infections, sulfathalidine treatment, 248.  
food, fit-producing, further tests, 387.  
hysteria due to feeding baked foods and wheat gluten flour, 234.  
neoplastic lymphadenopathies in, 105.  
nicotinic acid requirements, 135.  
potassium deficiency, 395.  
proteins, biological value, relation to absorbed nitrogen and nitrogen balance, 592.  
pyridoxine-deficient and normal, fate of tryptophan in, 601.  
streptomycin absorption and excretion, preliminary studies, 248.  
systemic blastomycosis, 387.
- Dogwood borer, biology and control, 352.
- Dolichos lablab*, parasitism of *Striga* sp. on, 513.
- Dominican Republic, coffee, 507.
- Dough(s)—see also Bread.  
freezing before baking, 124.  
gluten disintegration, effects of papain, yeast water, cysteine, and glutathione, indications, 609.  
gluten dispersion, effects of papain, yeast water, cysteine, and glutathione, indication, 609.  
mixogram patterns, effect of fermentation, rest periods, and formula ingredients, 307.  
oxidizing agents, 297.
- Doves, species-specific antigens, segregation in backcross of species hybrids, 188.
- Dragonflies, economic importance, 533.
- Drier(s)—  
experimental, for pre-pilot plant studies, 770.  
hay, flatted floor barn, handbook on design, 862.
- Drought, effect on trees in prairie climate, 167.
- Drug(s)—  
antimalarial, studies in vitro, 241.  
inspection and analysis reports, Conn. [New Haven] 122.  
plants—  
of Mexico, book, 181.  
tests for Puerto Rican culture, P.R.U. 55.
- Dry-cleaning solvents, compositions and trade names, 140.
- Duck(s)—  
blood, oxygen transport, 710.  
disease at Tulare Lake, 253.  
food at Reelfoot Lake, Tenn., 523.  
infected with *Plasmodium lophurae*, continuous intravenous chemotherapy, 251.  
nesting boxes, wood, use in Wheeler Wildlife Refuge, Tenn., 523.  
nutritional studies, I, purified rations, 419.  
nutritional studies, II, pyridoxine deficiency, 420.  
wild, pasteurellosis outbreak, 398.  
wild, pasteurellosis treatment, 398.
- Duckling(s)—  
intracerebral passage of modification of strain of Newcastle disease virus, preliminary, 721.  
vitamin D requirements, 552.
- Dunes, soil material, 479.
- Dust(s)—  
control of hairy chinch bug, 833.  
dilutents, diatomaceous, 688.
- for potato—  
demonstration plots, 1945, 211.  
early blight fungus, evaluation, N. Dak. 211.  
insect pests, evaluation, N. Dak. 211.  
new, in control of insects and diseases, 355.  
rotenone, toxicity, effect of mineral composition and particle size in dispersants, 832.  
zinc-bearing, trials, 821.
- Dusters for apple scab control, 827.
- Dusting—  
orchards by airplane, 72.  
sugarcane borer with cryolite, 360.
- Duvel buried seed experiment, final results, U.S.D.A. 201.
- Dye(s)—  
employed in biological laboratory, nature and uses, handbook, 778.  
sulfate-reducing bacteria inhibited by, 32.  
titration for ascorbic acid, specificity, 602.

- "Dyne," new dairy product, 852.
- Dystocia in cows from uterine torsion, instrument for relieving, 100.
- East coast fever—see also African coast fever.
- in cattle, spread by *Rhipicephalus neavei*, 1912, 230.
- Economic—
- and cultural development of people in Virginia, 587.
- outlook in Sumter, S.C., S.C. 865.
- Economics—
- agricultural—
- papers, 578.
- papers and notes, 579.
- postwar problems and programs in Nebraska, committee reports listed, Nebr. 111.
- research by experiment stations, progress reports (1945), U.S.D.A. 142.
- research progress report, Ohio 110, U.S.D.A. 140, 141, Ala. 143.
- home—see Home economics.

in lambs—  
control by alum-precipitated toxoid, 855.  
treatment by sulfur, Colo. 856.  
ovine infectious, in Colombia, 104.
- Entomology—  
economic, research involvements, 532.  
future of, 77.  
in cereal industries, 85.  
nomenclature and literature, new edition, 332.  
research by experiment stations, progress reports (1945), U.S.D.A. 142.  
research progress reports, U.S.D.A. 140, 141, 142, Ala. 143.
- Entomology and Plant Quarantine, Bureau of, report of Chief (1945), U.S.D.A. 140, 141.
- Entomysus fragilis* n. sp., description, 369.
- Environment, factors and control in plant experiments, 781.
- Enzymatic synthesis of dextran from sucrose, 765.
- Enzyme(s)—  
bacterial, extraction by ultrasonic disintegration, 634.  
effect on penicillin, 32.  
light-sensitive, in milk, 259.  
pectinol A, effect on pectin and other substances, 5.  
proteolytic, effect on raw and heated casein, 449.  
relationships in utilization of soybean oil meal phosphorus by rat, 596.  
role in wheat technology, volume, 762.
- Enzymology, advances, and related subjects of biochemistry, VI, volume, 762.
- Homocanthus stramineus*—see Chicken body louse.
- Ephemoptera, new species, 830.
- Epilachna varvvestis*—see Mexican bean beetle.
- Epione mollicularia*, descriptive and taxonomic notes, 80.
- Epitrix tuberis*—see Tuber flea beetle.
- Epourenia viva* n. gen. and sp., description, 686.
- Epoxides, in food-spoilage prevention, 126.
- Erechthias fulguritella* in pine cones, 226.
- Ergosterol, irradiated (D2), antirachitic potency for growing pigs, 376.
- Erosion—  
control and reclamation of eroded sandy clay lands of Texas, Arkansas, and Louisiana, U.S.D.A. 631.

## Erosion—Continued

## soil—

- bambo controlling, 26.
- book, 26.
- early investigations, 785.
- effects of pocket gopher on mountain range, 349.
- in central New York, [N.Y.] Cornell 311.
- in small irrigation furrows, Utah, 570.
- wind, dynamics—
- III-V, 172.
- VI, sorting of soil material by wind, 479.

Erysipelas—see *host*.

*Erysipelothrix rhusiopathiae* infections in mice, chemotherapy, 389.

Erysiphaceae of China, further studies, 209.

## Erysiphe—

- new variety in China, 209.
  - polygoni*, cause of powdery mildew of broad bean in Yunnan, China, 337.
  - spp. conidial germination, mechanism, 61.
- Erythroleucosis, incidence following inoculation by various routes, 567.

*Erythroneura* of *obliqua* group from Ohio and Tennessee, 221.

*Erythroneura* of *vulnerata* group, keys and one species, 353.

*Escherichia coli*, sensitivity to radiation, inherited differences, 651.

Estrogens—see also Hormones, estrogenic. effect on meat quality of old cocks and hens, 709.

feeding, fattening potency in chicks, rapid assay method, 46.

synthetic, activity on oral administration in domestic fowl and turkey, 234.

synthetic, capon production, 190.

## Estrus, induction—

by equine gonadotropin in lactating sows, 46.

in ovariectomized hamster, 189.

Ethane, 1,1,1-trichloro-2, 2-bis (*p*-chlorophenyl)—see DDT.

Ethyl formate, fumigant for dried packaged fruit, 77.

## Ethylene dibromide—

as fumigant for Japanese beetle, 77.

wireworm control by, 82.

2-Ethylhexanediol-1, 3, insect-repellent properties, 79.

Eucalyptus, planting in Ecuador Sierra, U.S.D.A. 206.

*Eufidonia* larvae, new descriptions, 364.

*Euhomogamasus sciuropteri* n. sp. from squirrel, 369.

*Eulithobius*, new species, description, 351.

*Euphorbia calycina*, insecticidal properties of extracts, 80.

*Euphorbia tirucalli*, insecticidal properties of extracts, 80.

Euphorbiaceae, seed development, 797.

*Euplioides*, new oriental subgenus of *Crosocerus*, with descriptions of new species and subspecies, 355.

## European—

apple sawfly in Connecticut, 352.

chafer, *Amphimallon majalis*, and control in lawns, 696.

## corn borer—

control by low-temperature fumigation, 356.

tachinid parasite, 83.

## red mite—

DDT sprays and populations, 77.

life history, Va. 835.

*Euschistus impictiventris*, damage to sugar beets grown for seed, 834.

*Euschistus* spp., life history, 695.

*Eutrichophilus* spp. on rodents, descriptions, 88.

*Eutrombicula batatas*, habits and life history, 544.

Evaporation regions in United States, 475

## Ewes—

aneestrous, induction of mating and lambing following pregnant mare serum administration, 801.

## breeding—

nutritive needs, 91, Idaho 92.

wintering in Alaska, Alaska 92.

colostrum, vitamin contents, 98.

ketonemia in fetus of, 100.

pregnant, blood glucose and acetone bodies, influence of protein starch diets, 375.

Experiment stations—see also *specific names*. workers in subjects pertaining to agriculture, 1945-46, U.S.D.A. 875.

## Office of—

eleventh annual survey, 265.

notes, 447, 759, 912.

report of Chief (1945), U.S.D.A. 141, 142.

report on agricultural experiment stations (1945), U.S.D.A. 142.

Experimental techniques, agrobiological test for normality in fertilizer and variety comparisons, 173.

Experimental techniques, block designs for insect population problems, 77.

## Extension—

methods and techniques, contribution to rehabilitation of war-torn countries, conference report, 1944, U.S.D.A. 265.

work, cooperative, in agriculture and home economics, report, 1945, U.S.D.A. 734.

workers, radio handbook for, U.S.D.A. 121.

Extensograph, preliminary studies, 291.

Extractor, for atmospheric or reduced pressure use, 149.

Eyes, biomicroscopy in evaluation of nutritional status, 427.

Fabrics—see also Textiles; *specific kinds*.

action of antiperspirant creams, 899.

cellulose, flow properties of cuprammonium dispersions, fluidity calculations, 138.

DDT-impregnated, effect on insects, 85.

flameproofing, durable, for cotton outer garments, 484.

flammability, basis of evaluation, 434.

## Fabrics—Continued

- knitted, made of natural and mercerized carded and combed cotton yarns, physical properties, 433.
- lining, abrasion, 434.
- pest deterrents, evaluation, 435.
- research progress reports, U.S.D.A. 141, 142.
- resistance to insect pests, increase, compounds for, valuation, 435.
- rotproofing, dimethylgloxime-copper treatment, 900.
- waterproof, tests, devices for producing artificial rainfall, 750.

## Fall cankerworm, egg parasitism, 352.

## Family(ies)—

- dietary level of 100, study, 274.
- farm, incomes and living costs in Kansas, Kans. 139.
- food selection of 80 in Lubbock, Texas, further analysis, 275.

## Fanweed seed, concentrate for milk cows, Mont. 849.

## Far East, war damage, report, 608.

Farm(s)—*see also specific kinds.*

- business report (1944), Mich. 111.
- family-operated, typical, 1930-45, adjustments, costs, and returns, U.S.D.A. 582.
- historical look to future, U.S.D.A. 583.
- income(s)—
  - and living costs in Kansas, Kans. 139.
  - and national income, 724.
  - index numbers (1945), Ohio 110.
  - postwar, U.S.D.A. 110.
  - report (1944), Mich. 111.
- job analysis, result in labor saving, II, hay harvesting, Vt. 728.
- land—*see* Land(s); Real estate.
- machinery—*see* Machinery.
- management in Oneida County, N.Y., 1942-43, [N.Y.] Cornell 403.

  - program of services, U.S.D.A. 118.
- Farmer(s)—
  - cooperation in meeting emergency labor needs during war, Mich. 732.
  - cooperatives—*see* Cooperative(s).
  - in modern world, 863.
  - income, gross cash, from sale of produce and from A.A.A. payments, in Ohio, 1943-44, Ohio 405.
  - low-income, program of services to, U.S. D.A. 118.
  - of Finnish heritage in Michigan, general survey, Mich. 118.
  - postwar purchase and improvement plans, Md. 731.
  - price control stake of, W.Va. 118.
  - subsistence, war relocation, Ohio 732.
- Farmhouses, midwestern modernizing, Iowa 110.
- Farming—*see also specific kind.*
  - capital needed for, in Midwest U.S.A., Minn. 117.
  - cash receipts, by States and commodities, calendar years 1924-44, U.S.D.A. 585.
  - changes in war and peace, U.S.D.A. 863.
  - dairy—*see* Dairy farm(s); Dairy farming.
  - opportunities, improvement by agricultural adjustment, S.C. 865.
  - peacetime adjustments, 403.
  - practices, Michigan, type-of-farming area 9, Mich. 260.
  - scale, economies in southern San Joaquin Valley, Calif., U.S.D.A. 864.
  - southern, facts, U.S.D.A. 261.
  - systems and practices, red soil area, Tennessee, 1944, Tenn. 738.
- Farmstead—
  - lighting, planning, U.S.D.A. 257.
  - wiring, planning, U.S.D.A. 257.
- Fasciola hepatica*—*see* Common liver fluke.
- metacercariae, ecology, 387.
- Fat(s)—*see also specific kinds.*
  - acids—*see* Fatty acids.
  - antioxidants, evaluation by stability values obtained by rapid methods, 471.
  - antioxidants, fatty acid monoesters of L-ascorbic and D-isoascorbic acids, 462.
  - chlorophyll content, fluorescence, relation to rancidity, 453.
  - comparative nutrient values of butterfat vs. margarine, 129.
  - deterioration, problems of Army, 413.

## Fat(s)—Continued

- dilatometric investigations, I, II, 452.
  - effect on resistance of rats to anoxic anoxia, 739.
  - effect on utilization of galactose by rat, 422, 454.
  - esters, unsaturated, peroxides, formation and decomposition, 462.
  - fatty acid monoesters of *L*-ascorbic and *D*-isoascorbic acids in, assay, 19.
  - food, flavors in, 121.
  - hog, stability, relation to fatty acid composition and tocopherol contents, 627.
  - in cereal products, oxidative deterioration, 266.
  - in wheat starch, extraction, 3.
  - metabolism, effect of B vitamins, tests with choline, 594.
  - of poor keeping quality, stabilizing agents, 460.
  - oxidized, stabilization by steam deodorization with phosphatic acid or commercial lecithin, 453.
  - oxygen absorption, rate, determination apparatus, 299.
  - rancid, toxicity, 266, 389.
  - stability values, active oxygen method and storage in glass vials, 453.
  - thermal properties, I-V, 455.
  - thiocyanogen reagent and method, modified, 472.
  - vegetable, plastic, consistency measurement by standard micro-penetration technique, 455.
- Fatty acid(s)—
- chain length, effect on fatty liver of choline deficiency in rats, 129.
  - components of soybean lecithin, 465.
  - composition of—
    - linseed oil, relation to iodine number, 463.
    - soybean oil, relation to iodine number, 460.
    - tobacco seed oils, 461.
  - distribution pattern in glycerides of milk fat, 384.
  - free, in dried egg powders, estimation, factors influencing, 774.
  - higher, acyl phosphates, synthesis and properties, 464.
  - methyl esters—
    - oxygen absorption, and effect of antioxidants, 464.
    - vapor pressures, 5.
  - monoesters of *L*-ascorbic and *D*-isoascorbic acid as antioxidants for fats and oils, 462.
  - of corn oil, 295.
  - polymeric, allylic esters, 464.
  - unsaturated, effect on acid production of *Lactobacillus helveticus*, 553.
  - unsaturated, effect on *Lactobacillus helveticus* and other gram-positive microorganisms, 295.
  - volatile, in cheese, determination, simplified extraction-distillation method, 774.

## Fatty acid(s)—Continued

- volatile saturated, separation and identification, 16.
- Fatty materials, mono unsaturated, hydroxylation with hydrogen peroxide, 291.
- Feces, metallic elements, spectrographic determination, 304.
- Federal Crop Insurance Corporation, report of Manager (1945), U S D A. 117.
- Feed(s)—
- animal, digestibility measured by experiments with rats, 275.
  - animal, supplement, fused tricalcium phosphate fertilizer, 811.
  - cattle, identification and measurement of rate of passage through rumen, 841.
  - fattening, for cattle, Ariz. 90, Wash. 91.
  - livestock, green feed supplements in, 90.
  - low-potency, riboflavin assay, 160.
  - pigs, synthetic nutrient added to protein supplements, 93.
  - samples, official, analyzed by Kentucky Agricultural Experiment Station, quarterly report, 546.
  - sulfur in, assay methods, 20.
  - sulfur in, determination by nitric and perchloric acid digestion procedure, 156.
- Feedstuffs, apparent digestibility coefficients, estimation by inert "reference substance," 703.
- Fence posts—
- cold-soaking in pentachlorophenol solution, convenient method, 669.
  - preservative treatments, Colo. 206.
- Fermate, control of cucumber anthracnose, 827.
- Fermentation(s)—
- 2,3-butylene glycol in, assay technique, 16.
  - liquors, cereal, 2,3 butylene glycol recovery from, 164.
  - liquors, lactic acid content, determination, 302.
  - media, citric acid assay, 11.
- Fertility, differential human, in Louisiana, La. 874.
- Fertilization, double, in petunia, 11.
- Fertilizer(s)—
- aluminum dress as, 30.
  - analyses, checks on methods and solutions, 13.
  - application with plow, Minn. 312.
  - balanced use by soil tests for potassium and phosphorus, 174.
  - bibliography, 1940-44, 781.
  - commercial—
    - in Colorado, 444.
    - inspection, season 1945, Mass. 790.
    - report for 1945, Conn. [New Haven] 313.
  - effect on crop yields and composition, 173.
  - experiments, agrobiologic test for normality in, 173.
  - for Utah, 1946, Utah 312.
  - inspection, analysis, and use, 1944, 313.

## Fertilizer(s)—Continued

- mixtures, ammonium nitrate and organic material in, 30.
- needs of soil, determination by leaf analysis, basis, 321.
- plant foods in, prewar world production and consumption, 482.
- potash determination in, factors influencing, 151.
- recommendations for Mississippi, 1946, Miss. 312.
- research progress reports, U.S.D.A. 140, 142, Ala. 143.
- resources, production, marketing, and use U.S., U.S.D.A. 632.
- sewage sludge (digested) as, 29.
- supplements to high-analysis, 177.
- use and crop yields, bibliography, U.S.D.A. 790.
- yield-depression effects, 27.

## Fetal membranes, retained—

- by cattle, blood picture, 854.
- pyometra following, effects of stilbestrol, 392.

## Fibers—

- coarse, from proteins, 163.
- cotton, wax determination by alcohol extraction method, 155.
- research progress reports, U.S.D.A. 141, 142.
- textile, from casein, 163.

*Picus benjaminii*, Cuban-laurel thrips control, 836.

## Figs, freezing storage, 882.

## Filarial dermatitis of sheep, treatment with antimony compounds, 856.

## Filariasis, canine, treatment with trivalent arsenicals, 387.

## Flier fly, control by DDT, 697, 698.

## Filters, glass bacteriological, arranged for positive pressure, 634.

## Fire ant, control by DDT, 696.

## Fire, in longleaf-slash pine type, effect on grazing, 57.

## Fire, spread in light forest fuels, 56.

Fish(es)—*see also specific kinds*.

- bassalian, parasites, 351.
- condition, calculation from scale dimensions in bluegill, 350.
- detector combined with photoelectric light meter, 525.
- distribution—
  - depth, in lower Wheeler Reservoir, Ala. 526.
  - in Puerto Rican waters, P.R.U. 76.
- fresh-water, new parasite, 351.
- from Michigan waters, nutritive value, I, nicotinic acid of herring, carp, suckers, and burbot, 744.
- liver oil, effect on secretion of vitamin D in mother's milk, 748.
- metacercarial infections, and cercarial production in snails, Carroll Lake, Wis., 351.
- parasites in northern Wisconsin, 77.

## Fish(es)—Continued

- species, food in Norris Reservoir, Tenn., 527.

## Fishery industries, insect control in, by DDT, 85.

## Fishing—

- and marketing in Puerto Rico, general study, P.R.U. 76.
- spring, effects of water temperature, Norris Reservoir, Tenn., 526.
- spring, on TVA storage reservoirs, 1945, 526.

## Fishponds, farm, management, Ala. 143.

Flag smut—*see* Smut, flag

## Flame weeding, efficacy, N.Y. State and Cornell 401.

## Flameproofing cotton fabrics for outer garments, 434.

## Flammability tester, operating instructions and test procedure, 604.

## Flannagan-Hope Act for Agricultural Research, 447.

## Flat grain beetle, life history and habits, 365.

Flavin adenine dinucleotide, utilization by *Lactobacillus casei*, influence of riboflavin, 179.

## Flax—

- choline content, 273.
- hypocotyledonary buds, development, influence of carbohydrate and nitrate-nitrogen nutrition, 322.
- seed treatment tests, cooperative, in 1945, 335.
- seedling disease caused by *Macrosporium* sp., 210.
- tetraploidy in, 186.
- wilt fungus, *Fusarium lini*, variation and variability, N.Dak. 210.
- zinc deficiency in, 66.

## Fleas of Puerto Rico, 229.

## Flies—

- control by concentrated sprays, 366.
- control with DDT, 366.
- locus of action of DDT, 530.

## Flight-vision correlations in insects, 78.

## Flooding, effect on forage crops, 192.

## Floods, notable, of 1939, I Colorado River Basin, II eastern Kentucky, III Baldwin Maine, 475.

## Flora(s)—

- of Alaska and adjacent Canada, 33.
- Part V, Cabombaceae to Droseraceae, Iowa 484.
- of Indiana, distribution records, 34.
- of Taylor County, Texas, notes, 638.
- wild and cultivated, of Pennsylvania, catalog, 484.
- world, history, 181.

## Florida Station—

- notes, 607.
- report, 1945, Fla. 901.

## Flour(s)—

- baking absorption, estimation with effect of variety and protein level, 622.
- from Missouri wheats for baking purposes, Mo. 411.

## Flour(s)—Continued

- gluten, cause of canine hysteria, 234.
- mill, sulfate-reducing bacteria in, treatment, 32.
- new, baking qualities, 876.
- of Kansas-grown wheat varieties, thiamine and riboflavin content, 280.
- wheat, "amylodextrin" fraction, composition, 451.
- white, enrichment, symposium, 876.

## Flower(s)—

- development-terminology in bulbous plants, 38.
- gardening, Mo. 205.
- seeds, quality on sale in New York, 1945, N.Y. State 333.
- wild, of Mississippi, popular bulletin, Miss. 180.

Flowering in plants, correlation with nitrogenous food and photoperiod, 185.

"Flue dust," production of sun scald on tomato seedlings, 345.

Fluff louse, control by DDT, 88.

Fluidity values, calculation, 138.

Fluke, new, from badger and other mustelids, description, 522.

Fluoride, determination in water, 300.

Fluorimetry, of pigments by fluorescence intensity, 12.

## Fluorine—

- content of soils, 788.
- deposit, injury to apricot leaves, 517.
- in bones and minerals, assay, 19.
- in milk, plant foods, and foods cooked in fluorine-containing water, 273.

Fodder, green, carotene content, vitamin A activity, 545.

Folilage fungicides, gloxalidine derivatives, I, II, 509.

## Folic acid—

- compounds, liberation, 616.
- excretion through skin and in urine of normal individuals, 600.
- formation by incubating *Lactobacillus casei* factor and pyracin with chick liver, 616.
- guinea pig requirements, nature of new, 138.
- importance in low nicotinic-acid rations in dogs, 135.
- in nutrition of certain insects, 685.
- synthetic, activity in purified rations, 549.

Folic acid-like material, microbiologically inactive, vitamin activity in rat, 134.

Follicle-stimulating hormone, ovarian effects on chicks and hens, 189.

## Foods(s)—

- absorption of fluorine from cooking water, 273.
- allotment, national program, 724.
- and dietary habits of Filipinos in Hawaii, Hawaii 734.
- canned—see Canned foods.
- carotene, extraction and assay, 17.
- carotene, values, measurement by storage of vitamin A in rats' livers, 278.
- chemistry, textbook, seventh edition, 410.

## Food(s)—Continued

- compression, peacetime, 414.
- consumption levels in U.S., Canada, and United Kingdom, U.S.D.A. 590.

consumption of albino rat, seasonal changes and rate of growth, 275.

decomposed, technique of study, 8.

## dehydrated—

- cooking method, improvement, 589.
- sulfur dioxide determination in, 155.
- demand, and population growth, U.S.D.A. 119.

dried, carotene content, effect of storage, 892.

dry, materials, water content, determination by Fischer volumetric method, 617.

dry, water determination in, Fischer method, 150.

effects of soil elements, symposium, 272.

for young people and their families, book, 418.

freeze-drying, possibilities, 880.

## freezing—

- cooked, problems, 880.
- equipment and processes, N.J. 879.
- for home use, 123, La. 880.
- from freezer precooked or prepared, 589.
- frozen—see also specific kinds of foods; Locker plants.
- precooked, boon to housewife, N.Y. State and Cornell 880.
- problems reviewed, 124.

habits, Hawaiian, war effects, 127.

home-canned, surface darkening, prevention, 124.

human, digestibility measured by rats, 275.

inspection and analysis reports, Conn.

[New Haven] 122.

institutional equipment for, sanitization,

126.

intake of preschool children, factors influencing, 274.

investigation, literature, index, 588.

metallie elements, spectrographic determination, 304.

methionine determination, 773.

## Mexican—

- typical composition, 127.
- vitamin C content, new values, 281.
- nutrients, influence of cooking processes, N.C. 884.

## packaging—

- for postwar marketing, U.S.D.A. 126.
- gas penetration rate, determination, 149.
- gas penetration, rate measurement, 126.
- preparation, changing pattern in small-town families in Mississippi, Miss. 735.
- preparation equipment of small-town families, Miss. 884.

preservation by dehydrofreezing, new method, 879.

processing, electronics, new principles involved, 272.

processors, new germicides, 268.

products, dichloroacetic acid in, detection and assay, 16.

## Food(s)—Continued

- quality and flavor, papers listed, 121.
- research by experiment stations, progress reports (1945), U.S.D.A. 142.
- research progress reports, U.S.D.A. 140, 141, Ala. 143.
- riboflavin assay in low-potency, 160.
- selection of 80 families in Lubbock, Texas, further analysis, 275.
- served in cooperative residence hall for women, ascorbic acid content, 895.
- spoilage, and pressure-cooker gauges, 125.
- spoilage, prevention by epoxides, 126.
- supply of U.S., nutritive value, 884.
- tropical, representative values, tables, 588.
- tropical, riboflavin content, 745.
- value, estimation by chemical methods in India, 275.
- vitamin B<sub>1</sub> content, extraction procedures for assays, 18.

## Food and Agricultural Organization of the United Nations, report of conference (1945), 143.

## Foodstuffs, leucine content, 1.

## Forage—

- crop(s)—
  - chemical composition, effects of soil treatments, Ill. 481.
  - diseases, 334.
  - spring-flooding effects, 192.
- flat-pea, digestibility and composition at growth stages comparison, 91.
- grass diseases of North Central States, characteristics, U.S.D.A. 822.
- high-altitude in southwestern Colorado, Colo. 500.

- legume, potentialities of birdsfoot trefoil, 656.
- plant(s)—*see also* Plant(s).
  - breeding, competition, controlled, adaptation, designs and technique, 803.
  - nutritional value, factors affecting, 256.

## Forecasts, agricultural, postwar, historical perspectives, 1870-1940, 863.

## Foreign Agriculture—

- February-March 1946, 263.
- April 1946, U.S.D.A. 403.
- June-July 1946, U.S.D.A. 724.
- August-September 1946, U.S.D.A. 911.

## Forest(s)—

- Brazilian, yellow fever virus, hosts and vectors, annual cycle, 219.
- credit, 1930-45, U.S.D.A. 206.
- fires, spread in light forest fuels, 56.
- game—*see* Game.
- from grassland in Kentucky "Big Barrens," 182.
- management, aerial photographs, specifications, 667.
- management, needs of timber requirements of post-war era and future, Miss. 667.
- of Ecuador, effects of war and postwar conditions, U.S.D.A. 334.

## Forest(s)—Continued

- tent caterpillar, diapause recovery and egg hatching, Minn. 225.

## tree(s)—

- diseases, 335.
  - in prairie climate, ecological relations, 167.
  - longleaf-slash pine, grazing, influence of burning, 57.
  - machine for planting, description, Mich. 109.
  - pruning by finger-budding method, 668.
  - seedlings, growth-regulator effects, 55, 56.
  - seeds, germination, effect of chemical treatments, 667.
  - water and related topics, U.S.D.A. 333.
- Forestry, research progress reports, U.S.D.A. 140, 142, Ala. 143.
- Forestry terminology, Spanish-English glossary, U.S.D.A. 667.

## Formaldehyde—

- control of onion smut, comparison with dust fungicides, Mich. 344.
- reaction with l(—)-histidine, 2.

## Formaldehyde-protein reaction, methylene bridges and unreactivity of benzoyl-d(—)—alanine, 764.

## Formic acid, content of high-temperature heated milk, 145.

*Formica csectoides*—*see* Allegheny mound ant.

## Foulbrood, American—

- control by sulfa drugs, 544.
- disease of honey bees, sulfathiazole, medication, 702.
- simple field test, 370.
- treatment with sulfa—
  - experimental report, 702.
  - opposition, 840.

## Four-spotted pea beetle, egg production, in fluence of population number, 361.

Fowl(s)—*see also* Chick(s); Chicken(s); Poultry; Turkey(s).

- artificially infected with *Salmonella*, carriers, 252.
- ascarid, resistance, factor of hydrogen-ion concentration, 388.
- blood and tissue chemical studies, 378.
- bone tumors injected intravenously with Rous sarcoma pathogene, 396.
- breeding for egg production and quality, U.S.D.A. 41.
- breeding for lymphomatosis resistance, U.S.D.A. 42.
- calcium supplements for, sources, comparison, 95.
- cholera—*see also* Pasteurellosis.
  - domestic, synthetic estrogens, activity on oral administration, 234.
  - incubation temperature, effects on character expressions, 188.
- Fowls, laying, day-length effects, Fla. 96.
- lice, control by DDT, 88.
- low-producing, ovarian effects of FSH and LH, 189.

## Fowls—Continued

lymphomatosis transmission, 567.

Malayan virus disease, 397.

male—

breeding, selection by sisters' performance, 44.

sexual maturity inheritance, 45.

nematode *Ascaridia galli*, glycogen utilization in vitro and in vivo, 397.

neoplastic disease, history, incidence, and seasonal variation, 396.

plague investigations in war research program, 567.

poisoning by experimental zinc phosphide, 397.

progeny tests, number of daughters necessary, 497.

salmonella types, occurrence and distribution, I, isolation from hen's eggs, 252.

sarcoma, transmissibility, influence of genetic factors, 326.

Single-Comb White Leghorns, iris-color relation to egg production and mortality, 97.

temperature effects on energy and gas metabolism from hatching to maturity, 96.

toxicity of sodium chloride, 566.

typhoid—

diagnosed in guinea fowl, 860.

efficacy of recently developed sulfonamides, 860.

infection, control by sulfa drugs, 568.

vitamin supplements in rations of breeding and laying, 95.

## Fox(es)—

carotene utilization, comparison with vitamin A, [N.Y.] Cornell 521.

in Wisconsin, 682.

reproduction, effect of mating time, 520.

France, physiological races of *Puccini graminis tritici*, 512.*Fraxinus* spp., epidermal characters differentiating, 38.

## Freezer(s)—

home, construction, Minn. 402.

home, development, 578.

Freezing—see also Agricultural products;

Food(s); Fruit(s): Lockers; Meats;

Vegetables; *specific kinds*.

batters and doughs before baking, 124.

level and thunderstorms, 167.

Froghoppers, on sugarcane, insecticidal trials, 84.

## Frost—

apple drop after, prevention by growth substances, 51.

injury to hillculture plants, variations, 475.

protection to fruit crops, ineffectiveness of infra-red rays and smoke, 816.

spring, with special reference to frosts of May 1935, 779.

Frozen foods—see Food(s) frozen; *specific kinds of food*; Locker plants.

Fructosan, synthesis, mechanism in frozen beets, 184.

## Fruit(s)—

and pressure-cooker gauges, 125.

blanching and cooling for frozen pack, 417.

blanching, by steam and sulfur, 126.

canning cooperatives, status, 1943-44, U.S.D.A. 584.

crop diseases, 335.

crops, frost protection, ineffectiveness of infra-red rays and smoke, 816.

cut dehydrated, production, new methods, I-III, 270.

dehydrators, farm, mechanical features, 110.

dried packaged, fumigants for, 77.

## freezing—

at home, U.S.D.A. 418.

preservation, 124.

preservation, varieties for, 124.

## fresh—

nutritive-value retention, 121.

shelf life, lengthening, Ohio 877.

freshness, preservation from harvest to consumption, 266.

frozen, in bulk packages for home use, Minn. 589.

granules, preparation and uses, 588.

growth and ripening, seed-pericarp relations, 38.

juices, preservation, German methods, 417.

pests, control in Kansas, Kans. 816.

preservation, by sulfur dioxide solution, 126.

processed, Government inspection, questions and answers, U.S.D.A. 404.

products and byproducts, 265.

small, dehydration, 123.

soft, insect pests, control by DDT, 363.

spoilage prevention by epoxides, 126.

stone, bacterial canker, 678.

sulfur dioxide content, determination, 306.

three new varieties introduced by Minnesota Fruit Breeding Station, Minn. 331.

tree(s)—see also *specific kinds*.

airplane dusting practical, 72.

deciduous, little-leaf, treatment, 677.

growing for home use, Ohio 50.

pollination, Wash. 202.

root diseases, review, 72.

stickers for lead arsenate sprays, Conn. [New Haven] 531.

weather injuries, Va. 629.

varieties for South Dakota, S. Dak. 202.

vitamin C content, polarographic assay, 18.

weather injuries, Va. 629.

Fuel-oil emulsions, quick-breaking, containing DDT, 358.

Fuels, alcohol motor, iron pentacarbonyl as antiknock agent in, 165.

Fuels, nonpetroleum, automotive-engine usage, 108.

## Fumigation—

- chamber for methyl bromide—
  - construction and operation, Ala. 684.
  - determination by modified ethanolamine hydrolysis method, 152.
- low-temperature, control of European corn borer, 356.
- wheat, effect on viability and relation to baking quality, 813.

## Fungus(1)—

- antibiotics, production, 483.
- Chilean, hosts, preliminary list, with biographical references, 315.
- cultures, mites infesting, biology, classification, and control, 698.
- dictionary, 315.
- fleshy of Iowa, illustrations, VI, poroid forms, 315.
- flora of Utah and Nevada, U.S.D.A. 670.
- growth substances in parasitic and saprophytic, 59.
- microscopic mounts, preparation, use of Aerosol OT, 646.
- mold, electronic destruction, 126.
- mold, inheritance N.Dak. 180.
- pathogenic to man, action of sulfonamides, 315.
- plant-pathogenic, physiologic specialization, 60.
- seed-borne, IV, *Acremonia*, *Clamydo-mycetes*, and *Trichocladium*, 670.
- spores, aerial dissemination, U.S.D.A. 517.
- stale-medium effects on, 32.
- variation induced by bombardment with neutrons, 32.
- wood-destroying, alcoholic fermentation of carbohydrates and dehydrogenation of alcohols, 847.

## Fungicidal control of powdery mildew of cantaloups, Calif. 343.

## Fungicide(s)—

- analyses, 1945, Maine 201.
- and their action, book, 61.
- annual consumption and improvement needs, 508.
- copper—
  - cryolite compatibility with, 80.
  - mechanism of action, 62.
- dust, control of onion smut, comparison with formaldehyde, Mich. 344.
- eradication of *Colletotrichum lilii* in lily bulbs, 347.
- for—
  - foliage, glovalidine derivatives, I, II, 509.
  - garden seeds in western Washington, Wash. 215.
  - plant diseases, new and old, Colo. 336.
- new developments, 356.
- organic, new—
  - apple-disease trials, 72.
  - testing, (1945), 62.
- organo-mercurial, effect on potato dry rot incidence, 67.
- phenolic, quantitative determination, 778.

## Fungicide(s)—Continued

- polymeric organic polysulphides, 510.
- research basis, physiological and biochemical, 821.
- sold during 1945, analyses, N.J. 816.
- textile, effectiveness 899,
- funnels, weighing, descriptions, 149.
- Furfural-yielding constituents of wheat straw, as influenced by sodium hydroxide solutions, 6.
- Furnishings, fabric, sewing for home, book, 485.
- Fusarium*—
  - avenaceum*, potato wastage in storage by *F. caeruleum* vs., 67.
  - caeruleum*, potato wastage in storage by *F. avenaceum* vs., 67.
  - disease of prickly pear, 829.
  - javanicum*, antibacterial pigment, 314.
  - lini*, cause of flax wilt, variation and variability, N.Dak. 210.
  - oxy-sporium cubense*, inhibition by Meredith's actinomycete, 60.
  - wilt of tomato—
    - relation to plant nutrition, 515.
    - resistance, interpretation, 516.
- Fusiform rust, threat to slash pine plantations, Miss. 219.
- GR—S latices, densities, measurement, 767.
- Galactose ethers, preparation, 293.
- Galactose utilization by albino rat, effect of fat, 454.
- Gallnuts, Chinese, general study, 57.
- Galls, bacterial plant, and causal agents, comparisons, 59.
- Galls, powdery, of Lauraceae, 681.
- Gallus domesticus*, twin production, 803.
- Game—
  - food plants, soil-fertility standards, 520.
  - forest, restoration and management, Pittman-Robertson contributions, 681.
  - in Nova Scotia, report, 1945, 681.
- Ganoderma root rot of citrus, 679.
- Gapeworms of galliform and passeriform birds in New York State, 369.
- Garbage disposal on farm, U.S.D.A. 724.
- Garden crops, diseases in Georgia (1945), U.S.D.A. 58.
- Garden, home, disease losses, reduction, Miss. 675.
- Gas(es)—
  - combustion of producer, thermodynamics of, 162.
  - digester, automobile usage, 109.
  - penetration through food packages, rate measurement, 126.
- Gas-holder waters, fouling, prevention, 32.
- Gasolene, digester gas substitute for automobiles, 109.
- Gastroenteritis—
  - outbreak from *Salmonella pullorum*, 252.
  - transmissible, in pigs, 304.
- Geese, Canada, age and sex criteria and weights, 523.
- Gel powders, pectins, dispersibility due to sugars, 413.

- Gelatin, influence on nicotinic acid requirement of chicks, 549.
- Gene theory, new, and explanation of phenomenon of dominance to Mendelian segregation of cytogene, 493.
- Genera, names, abbreviations, 755.
- Genetic characters, in fowls, as influenced by incubation temperatures, 188.
- Geography, plant role in, 181.
- Geology, book, 143.
- Geometridae—  
   of Iowa, preliminary report, 534.  
   two new characters seen without dissection, 353.
- Gomylodocus* spp. on rodents, descriptions, 88.
- Georgia Station, report, 1945, Ga. 436.
- Geraniaceae, fourteen species, seed key, 316
- Germicides—  
   for dairy industry, 99.  
   new, for food processors, 268.
- Germination and seedling growth, III, 316.
- Ginkgo biloba*, cortex, pith, and procambium, development, origin and pattern, 493.
- Ginkgo biloba*, shoots, long and short, development, I, 493.
- Glacial anticyclone theory, examination in light of recent meteorological data from Greenland, I, 628.
- Gladiolic acid, antifungal and antibacterial metabolic product of *Penicillium gladioli*, 637.
- Gladiolus, botrytis corm rot, 74.
- Glassware, cold wet, writing on by wax pencils, 471.
- Globin, human or beef, inability to support normal hematopoiesis in rat without isoleucine, 737.
- Gloeosporium* sp., cause of dieback of camellia, Miss. 829.
- Glomerella cingulata* strain, cause of anthracnose of lespedeza, 671.
- Glossina* spp. of French West Africa, monograph, 700.
- Glucoscorbic acid, feeding to white rats, chickens, and guinea pigs, effects, 747.
- Glucose decomposition, oxidative pathway, [N.Y.] Cornell 766.
- Glucose, ethers, preparation, 293.
- d-Glucose-L-sorbose, isolation and structure of enzymically synthesized crystalline, 4.
- Glues, tacky and remoistening, peanut protein hydrates as, 164.
- Gluten dispersion or disintegration, effects of papain, yeast water, cysteine, and glutathione, indications, 609.
- Glycerin, supplement in water-soluble herbicidal sprays, 814.
- Glucose in tissue slices, rapid microdetermination, 776.
- Glycerides, feeding to rats in nutritional studies on milk fat, 555.
- Glycols, di- and triethylene as manostat fluids, 770.
- Glycosides, acetyl groups in acetates of, microdetermination, 153.
- Glycosides, hydroxyl content, microdetermination, 153.
- Glycine, biological conversion of L-serine to, 450.
- Glyoxalidine derivatives, fungicidal value for foliage, I, II, 509.
- Gnorimoschima operculella*—see Potato tuberworm.
- Goat(s)—  
   abscesses in, *Corynebacterium ovis* causing (?), 104.  
   listerellosis case, clinical and laboratory study, 104.  
   live weight versus metabolic body size, 711.  
   muscle meat, protein value, comparison with cow and buffalo, 275.
- Gold, organic compounds, synthesis, 296.
- Golden nematode on Long Island, N.Y. State and Cornell 825.
- Gonadotropin(s)—  
   chick response to, 189.  
   chorionic, effects on cystic ovaries in cow, 392.  
   equine, estrus in lactating sows induced by, 46.  
   ovarian effects on chicks and hens, 189.
- Goniocotes hologaster*—see Fluff louse.
- Gopher, pocket, relation to soil erosion on mountain range, 349.
- Goslings, vitamin D requirements, 710.
- Gossypol—  
   antioxidant activity, temperature effects, 6.  
   carotene-protecting antioxidant, 6.  
   in cottonseed—  
     and cottonseed meal, assay of extractable, 14.  
     meal and meats, estimation, 776.  
     oil, estimation, spectrophotometric method, 776.
- Government institutions, local, financing in nine Vermont towns, VI, 733.
- Government, local, economic study in fifty Vermont towns, VI, 868.
- Grade labeling, teaching, 734.
- Graft inoculations with affected fruit tissue, means of transmission of peach wart, 827.
- Grain(s)—  
   choline content, 273.  
   feed, production and consumption in war and peace, U.S.D.A. 260.  
   root rots and leafspots, in northern Great Plains and Western States, U.S.D.A. 821.  
   small, straw strength, [N.Y.] Cornell 803.  
   spoilage in storage, 512.  
   storage, III, relation between moisture content, mold growth, and respiration of soybeans, 825.  
   stored, infestation by tyroglyphid mites, ecological studies, 539.  
   stored, insects, control by DDT, 539.
- Gramineae hybrids, artificial and natural, II, *Agropyron*, *Elymus*, and *Hordeum*, 798.
- Gramineae, hybrids, artificial and natural, I, *Elymus*, *Sitanion*, and *Agropyron*, 648.

- Granite grit, supplement to chick starting ration, 551.
- Grape(s)—  
 chlorosis experiments at Southern Great Plains Field Station, Woodward, Okla. 679.  
 court-noué, heteroauxin role in, 73.  
 frost injury in microclimatic areas, 475.  
 juice, *d*-isoascorbic acid as antioxidant in, 124.  
 juice, vitamin B stability, 279.  
 leaf skeletonizer, outbreaks and control in California, 695.  
 muscadine, freezing, 271.  
 performance, effect of climate in Michigan, 1945, 311.  
 Pierce's disease, virus causing, ten additional leafhopper vectors, 828.
- Grapefruit—  
 Florida, ascorbic acid concentration, seasonal changes, 283.  
 heart freezing, best methods, 881.  
 juice, ascorbic acid content, effect of commercial canning and short-time storage, 283.  
 juice, organic acids, 506.
- Grapevines, fruiting, weather conditions detrimental, 1945, Ohio 779.
- Grass(es)—  
 diseases, 334.  
 dormant, fungi isolated from, in North Dakota, 335.  
 fat and phosphatide content, 453.  
 for reseeding abandoned farm lands in Idaho, Ida. 654.
- forage—  
 preferences in high altitudes, Colo 500.  
 soil tests in Nebraska, 481.  
 spring-flooding effects, 192.
- grubs, control by lead arsenate, 83.
- hay and pasture—  
 palatability for sheep, Oreg. 843.  
 summary of research (1902-45), Alaska 190.
- new, Mandan wildrye and green stipgrass, N. Dak. 656.
- New Jersey swamp, 180.
- oil from Guatemala, U.S.D.A. 667.
- perennial range and pasture, roots, length of life, 501.
- phialea blind-seed disease, 69.
- prairie species following reseeding, establishment, 326.
- range, *Labops* damaging, 77.
- range, underground materials, annual increase, 317.
- root rots and leaf spots in northern Great Plains and Western States, U.S.D.A. 821.
- seed, harvesting, cleaning, and processing, techniques developed by U.S.D.A., Okla. 723.
- small-seeded, Iowa air-blast seed separator trials, Iowa 200.
- Xanthomonas translucens* parasitism, 62.
- Grasshopper(s)—  
 and locusts in Western Australia, 686.  
 and other Orthoptera of Arizona, index supplement, Ariz. 686.  
 baits, benzene hexachloride, 686.  
 feeding, differential, relation to local distribution, 353.  
 oviposition in coal pile, 221.
- Grassland—  
 change to forest in Kentucky "Big Barrens," 182.  
 improvement for northeastern U.S.A., U.S.D.A. 192.  
 range, succession in conservatively grazed, 191.  
 succession, quantitative study, 182.
- Gravel cultures, large-scale, for plant research, 783.
- Gray mold studies, 346.
- Grazing—  
 Alaska tundra, 349.  
 controlled, eradication of bindweed, Minn. 505.  
 in longleaf-slash pine type, burning effects, 57.  
 milk cows, effect of warm weather, 380.
- Great Basin, stream flow measurements, 1944, 399.
- Great Britain—  
 avian salmonellosis, survey, 721.  
 plant pathologists, recruitment and training, 669.
- Green—  
 dwarf of potato, virus disease, 824.  
 peach aphid, vector of—  
 beet mosaic and beet yellows, 70.  
 tobacco rosette, 71.  
 stink bug, control by sabadilla, 77.
- Greenbug of cereals in Uruguay, 688.
- Greenhouse, soils, chemical disinfection, 61.
- Greenland ice sheet, weather, control, 628.
- Grey lung virus, pathogenic for mice and other rodents, 683.
- Grouse, blue, blood parasites, 683.
- Growth regulators—see Plant growth regulators.
- Guar, germination, 808.
- Guatemala—  
 grass oil, U.S.D.A. 667.  
*Kaloterms nigratus* n. sp., description, 838.
- Guavas, vitamin C content, 283.
- Guayule—  
 betaine isolation from, 3.  
 cultivated, diseases and control, U.S.D.A. 679.  
 diploidia die-back, 680.  
 growth and rubber content, effects of variations in soil moisture stresses, 807.  
 growth in soil, relation of toxic substances to, 323.  
 morphology of reproduction, 324.  
 plants, toxic substances, relation to growth of guayule in soil, 323.  
 rubber in tissues, stain technique, 21.

## Guayule—Continued

- selections from natural population, evaluation, 196.
- thickly seeded, rubber production, 808.
- tissue, resin content, determination, rapid photometric method, 777.
- tissue, rubber content, determination, rapid photometric method, U.S.D.A. 777.
- transplanting, topping benefits in, 47.

Guinea fowls, infection with fowl typhoid, 860.

## Guinea pig(s)—

dietary factors essential—

VII, changes in distribution of plasma protein during deficiency, 592.

nature, 138.

immunization against *Brucella* infection, 244.

nutrition, vitamin A and carotene, 597.

Gulf Coast ticks, control by DDT in Florida, 542.

Gulley, Frank Arthur, and George Washington Curtis, two early agricultural teachers in Texas, 587.

Gum spirits, destructively distilled wood turpentine in, detection by aniline point, 21.

Gutta hydrocarbons in plant materials, differentiation, 777.

## Gypsum—

effect on plants grown on acid soils, comparison with lime, 787.

soil corrective and builder, Ariz. 28.

Gypsy moth, control, 352.

Habronemiasis, equine, xenodiagnosis, 105.

*Haemagogus* mosquitos in Colombia, 288.

*Haemagogus* spp., South American, life history and biology, 87.

*Haemaphysalis leporis-palustris*—see Rabbit tick.

*Haematopinus suis*, eradication by single treatment of DDT, 548.

*Haemolaelaps scalopi* n. sp. from mole, description, 369.

## Hail, variation in—

atmospheric concentration, 167.

physical properties, 167.

Hairy chinch bug, control by sabadilla and DDT, 833.

Hams, overseas, preparation, retention of thiamine, riboflavin, and nicotinic acid, 279.

Hamster, golden, ovariectomized, estrus induction, 189.

Hamster, rickets, experimental, 748.

*Haptoncus californicus* n. sp. description, 865.

Hardening, frost, in winter cereals, with gas change, 486.

Hardwoods, decay following glaze storm damage in New York, 820.

Hardwoods, southern, growth, wood, and uses, book, 507.

Harvester(s)—see also specific kinds.

## Hawaii—

*Apanteles trifasciatus* n. sp. from cotton bolls, 831.

## Hawaii—Continued

blossom midge, identity and host plants, 831.

foods used by Filipinos, Hawaii 734.

new urothripid, description, 831.

thrips, additions and new species, 830.

vegetables, Hawaii 734.

vegetables, iron availability, 595.

virus diseases of plants and their insect vectors, 820.

Hawaii National Park, plants illustrative of plants and customs of South Seas, treatise, 315.

## Hay—

barn-curing equipment, design, relation to resistance of hay to air flow, 576.

barn-drying, complications, Wis. 401.

barn-drying, success, Mass. 401.

carotene, preservation by autoclaving and waxing Wis. 297.

chemical composition, effects of soil treatments, Ill. 481.

crop, harvesting, U.S.D.A. 870.

cured partially, handling equipment, 575.

## curing—

in stack with forced air, 577.

systems, barn, rate of moisture removal, factors controlling, 255.

system, mow, requirements, calculation, 256.

## driers—

barn, slatted floor, handbook of design, 862.

forced ventilation, 255.

operation in Virginia, 573.

## Hay—

drying experience, seven years, 574.

grasses and legumes for, summary of research (1902-45), Alaska 190.

harvesting for labor saving, VI. 728.

Kobe lespedeza, digestibility, 231.

long, air distribution, 575.

loss of nutrients during storage, 370.

moisture absorption when exposed to atmospheres of various moisture content, Mich. 723.

prairie, feed value cut at different stages, progress report, 373.

preservatives, prohibitive quantities necessary for moist hay, N.Y. State and Cornell 328.

resistance to air flow and relation to design of barn hay-curing equipment, 576.

sweetclover, chemical composition and digestibility, effect of maturity, U.S.D.A. 545.

Haymaking machinery and methods, new, in western Nevada, Nev. 573.

Haymaking methods, Minn. 584.

## Health, rural—

conditions, survey, U.S.D.A. 120.

## facilities—

comparison with urban, Ohio 732.

in Missouri, Mo. 409.

- Health, rural—Continued  
 postwar problems and programs in Nebraska, committee reports listed, Nebr. 111.
- Heat transfer coefficients, calculation, nomograph, 862.
- Hedera helix*, mitosis-respiration correlation in, 37.
- Hedges, farm, use of multiflora rose, 817.
- Helminths—  
 bovine, incidence in Northern Nigeria, 245.  
 parasites of birds and mammals in western Massachusetts, 830.  
 parasites of skunks in Texas, 221.
- Helminthiasis, gastrointestinal, control in sheep by ten per cent cunic, 564.
- Helminthosporium*—  
 cause of blight of oats, 511.  
 sp., cause of new seed-borne disease of oats, 824.  
*turcicum* leaf blight of corn, 824.
- Hematopoiesis in rat, normal, necessity for isoleucine added to human or beef globin, 737.
- Hemicelluloses—  
 chemical investigations, Mass. 308.  
 quantitative estimation, 301.
- Hemiptera in potato fields of Sweden, 211.
- Hemoglobin formation following amino acids to rats fed low protein diet, 593.
- Hemoglobin regeneration by anemic rats, effects of iron compounds, 593.
- Hemp, American, yields and breaking strengths, effects of fertilizers, 808.
- Hemp, retting, I-III, 808.
- Hens—see also Chickens; Fowl(s); Poultry.  
 breeding, ration, significance of riboflavin level, 548.  
 choline requirements, 707.  
 diet, effect on efficiency of egg production, 547.  
 fed soybean oil meal—  
 effect on viability of progeny, 547.  
 supplements, effectiveness in increasing hatchability of eggs, 547.  
 feeding and management in laying cages, N. Mex. 706.  
 feeding (thiouracil, effect on thyroid gland of chicks, 234.  
 old, meat quality, effect of estrogens, 709.  
 ovulation frequency, relation to follicular atresia after surgery, 190.  
 ovulation, interruption by nonspecific substances, 189.  
 reproductive tract, effects of hypothermia, 653.  
 twin production, 803.
- Henry R. Carter Memorial Laboratory of U.S. Public Health Service, investigations, 540.
- Herbal of Rufinus, printing of thirteenth century manuscript, 30.
- Herbicide(s)—  
 carbon disulfide use, Calif. 48.  
 control of weeds in canning peas, Mich. 49.
- Herbicide(s)—Continued  
 toxicity and persistence in greenhouse plots relation to soil reaction, U.S.D.A. 478.  
 water-soluble, glycerin as supplement, 814.
- Herbs, savory, culture and use, U.S.D.A. 505.
- Hessian fly—  
 in spring wheat of southwestern North Dakota, N. Dak. 360.  
 infestations in Tennessee and Kentucky, 77.  
 resistance derived from W38 and durum P.I. 94587, inheritance, 500.  
 resistance in wheats, relation to temperature, 224.
- Heterauxine—  
 effect on cells of diseased plants, 207.  
 role in court-noué of grape, 73.
- Heterodera*—  
*major*, cereals root celworm in North Wales, 670.  
*marioni*, root-knot nematode, host-parasite relationships, II, effects of host on parasite, 348.  
*rostochiensis*, life history on Long Island N. Y., 69.  
*schachtii*, soil populations as influenced by cropping, 70.
- Heteronychia sanctae-helenae*, control by application of DDT to soil, 531.
- Heterozygosity—  
 effect in variability and vigor, 650.  
 in animals, reduction by inbreeding, 187.  
 maintenance in homothallic fungus species of *Neurospora tetrasperma* type, 651.
- Hexachlorethane-bentonite suspension for removal of common liver fluke from sheep, 856.
- Hexachlorocyclohexane, gamma isomer, control of *Boophilus australis* in Argentina, 700.
- $\gamma$ -Hexachlorocyclohexane, antiinositol effect, 760.
- Hexyl resorcinol, penetration into *Ascaris lumbricoides* var. *suis*, effect of surface substances, 242.
- Hibiscus*—  
*cannabinus*, fiber yield, influence of planting time and spacing, 197.  
*cannabinus*, seed yield, influence of planting time and spacing, 197.  
 cuttings, origin of roots, 35.
- Hide beetles, control by DDT, 837.
- Hillculture plants, frost injury, variations, 475.
- Histidine, determination in protein hydrolysates with *Leuconostoc mesenteroides*, 618.
- Histidine, utilization by man, 736.
- l(-)-Histidine, formaldehyde reaction, 2.
- Hog(s)—see also Pigs; Sows; Swine.  
 bacon, ration, effects of vitamin B and protein in supplements to barley and wheat, 376.

**Hog(s)—Continued**

- cholera, virus concentration in blood of artificially infected swine at different stages, 394.
- fattening on cull peas in dry lot, Idaho 705.
- fattening, cull peas protein supplement, 377.
- feeding for pork and lard production, U.S.D.A. 725.
- market, utilization of oats, effect of fineness of grinding, 377.

**Home—**

- demonstration agent, U.S.D.A. 410.
- economics—
  - leaders, development of, 120.
  - omnibus, textbook, 410.
  - research progress reports, U.S.D.A. 141.
- equipment—
  - postwar, 285.
  - shopping for, symposium, 285.

**Homemaking activities, time expenditures in 183 Vermont farm homes, VI. 751.****Honey—**

- pH values of samples compared, 89.
- invertive activity, relation to degree of pigmentation, 620.
- protection against metallic corrosion, 702.
- bees—*see also* Bees.
  - American foulbrood disease, sulfathiazole medication, 702.
  - central nervous system, lipid content, 230.
  - pollinators in production of hybrid cucumber seed, 370.
  - strong colonies and forces, re-emphasis, 840.
  - toxic action of dinitro compounds, 702.

**Hookworm, pathogenicity in lambs fed adequately, 563.****Hopvine borer and control in New York hop yards, N.Y. State and Cornell 361.*****Hordeum* hybrids, artificial and natural, 798.****Hormonal syndromes induced by unrelated chemicals, accompanying parthenocarp, 639.****Hormones—**

- adrenocorticotrophic, effect of various reagents on, 611.
- biological action, manual, 188.
- estrogenic—*see also* Estrogens.
- growth—*see* Plant growth hormones.
- sex—
  - biological action, manual, 188.
  - from animals, effects on dioecious plants, 485.
  - in veterinary practice, 241.
- tomato, greenhouse tests, Minn. 202.

**Horn fly—**

- control by DDT in Florida, 542.
- control by DDT in Kansas, 542.

**Horse(s)—**

- anesthetic, newly developed, 386.
- diseases, research progress reports, U.S.D.A. 99.
- farm power, factors affecting, Mich. 378.

**Horse(s)—Continued**

- foal, *Corynebacterium equi* infection, 100.
- habronemiasis, xenodiagnosis, 105.
- larynx, changes associated with laryngeal hemiplegia, 566.
- Morgan, U.S. farm, work and objectives, 44.
- Okinawa, sera, complement-fixing and neutralizing antibodies against Japanese B virus, 247.
- Palomino, genetics, 652.
- parasitic aneurysm, incidence, 395.
- penicillin dosage and blood levels, 566.
- salmonellosis outbreak, 247.
- strangles, chemotherapy, 100.
- "1050" poisoning, clinical observations, 720.
- tetanus, fatal, penicillin therapy, 395.

**Horticulture, research—**

- by experiment stations, progress reports (1945), U.S.D.A. 142.
- progress reports, U.S.D.A. 140, 142, Ala. 143.

**Hosiery, size and fitting standards, new device being perfected, 435.****Host-parasite check list revision, *Pisum*, 335.*****Hosta*, variegated, chondriosomal systems, involvement in seasonal changes in biological equilibria, 519.****Houma Station, sugarcane disease testing and initial seedling selection, 1945, U.S.D.A. 674.****House(s)—*see also* Buildings; Poultry Houses; Shelters.**

- ants, revision, U.S.D.A. 838.
- farm—*see* Farmhouses.

**fly(ies)—**

- brain and muscles, histological effects of sesamin, 540.
- control by pyrethrum and DDT aerosols, laboratory tests, 541.
- larval control by benzene hexachloride, 77.
- toxicity of DDT compounds and pyrethrum, comparisons, 229.
- future, planning, remodeling, and equipping, 436.
- new, building, book, 724.

**Household—**

- insects, control by DDT, 539.
- refrigeration, servicing, 724.

**Housing—**

- postwar, Nebr. 111.
- research progress reports, U.S.D.A. 140.

**Human—**

- beings, adult, protein requirements in individual foods and food combinations, 592.
- beings, utilization of  $\alpha$ -amino acids, III-IV, arginine and acetyltryptophane, 593.
- body, adult, chemical composition and bearing on biochemistry of growth, 292.
- body, choline excretion, effect of choline intake and environmental temperature, 422.

## Human—Continued

- bioassay technique for determination of physiological availability of vitamins, 425.
- respiratory quotient, response after glucose administration, effects of dietary carbohydrate, 594.
- Human Nutrition and Home Economics, Bureau of, report of Chief (1945), U.S.D.A. 140, 141.
- Humidity, atmospheric, relative, measurement, 309.
- Humidity, effects on cellulosic materials, including tire cords, 284.
- Hurricanes—
  - North Atlantic, and tropical disturbances of 1945, 629.
  - rainfall distribution analyzed, 23.
  - ring of violent upward convection, 23.
- Hy-Kresol, tail mites on mink controlled by, 88.
- Hybridization, interspecific—
  - in *Parthenium*, 39.
  - tetraploid carnations, 40.
- Hybrids—
  - species, cellular antigens, individual differences, 190.
  - trigeneric, *Elymus* × wheat × rye, 649.
- Hydrangea paniculata grandiflora*, rutin isolated from flowers, 9.
- Hydrobacteriology, marine, book, 30.
- Hydrocarbon(s)—
  - administration methods for sheep, 104.
  - chlorinated, insecticidal tests, 79.
- Hydrocarbon-alcohol mixtures, water solubility in, 166.
- Hydrocicia immanis*—see Hopvine borer.
- Hydrogen—
  - ion(s)—
    - and plant nutrition, 183.
    - concentration, effect on fungistatic activity of dinitro-*o*-cresol, 207.
    - determination, apparatus, 149.
  - peroxide, action on carbohydrates, 294.
  - peroxide, nitrate impurities in 30 percent, removal technique, 10.
- Hydrology, soil relations, apparatus for recording, 108.
- Hydrolysis, determination of tryptophane, phenylalanine and methionine, rapid procedure, 301.
- Hydroxyl, in organic materials, determination by macro- and semimicromethods, 154.
- Hydroxyls, microdetermination in glycosides and sugars, 153.
- Hygrometer, electric, simple theory, 474.
- Hypochlorite, effect on milk bacteria and chemistry, 8.
- Ice cream—
  - fruit purees, 853.
  - manufacture, invert sirup preparation, new methods, 765.
  - mix, dry, development, progress, 853.

## Ice cream—Continued

- mix, keeping quality, relation to separation temperature and heat treatment of skim milk, 558.
- sugar conservation, 99.
- technical literature for 1915, 558.
- vitamin source, 131.
- Ices, sugar conservation in, 99.
- Ichthiometer for charting migration times of perch, description, 525.
- Idaho Station, notes, 607.
- Idaho University, notes, 607.
- Idiodonus*, Mexican species, 221.
- Illinois Station, notes, 607.
- Illinois University, notes, 607.
- Incinerator beetle in Connecticut, 352.
- Income—see Farm(s) income.
- Incubation temperatures of eggs, effect on character expressions in fowls, 188.
- "Indalone," photochemical dimerization, 4.
- Index numbers of production, prices, and income, Ohio 872.
- India, malaria control by pyrethrum spraying, 698.
- Indiana Station, notes, 288.
- Indigobush, insecticidal properties, U.S.D.A. 832.
- 3-Indoleacetic acid, in corn kernels, isolation from immature, 35.
- Indophenol-xylene extraction method for ascorbic acid and modifications for interfering substances, 626.
- Industrial development, agricultural relations, Nebr. 111.
- Industry, heavy, pollution of atmosphere meteorological control, 780.
- Infants, nutrition relations to diets of mothers, 127.
- Influenza, swine, purified virus, formalin-inactivated, vaccination with, antibody response of swine, 718.
- Infra-red rays, ineffectiveness for frost protection to fruit crops, 816.
- Inheritance of production by animals, evaluation method, 798.
- Insect(s)—see also *specific kind and names*.
  - affecting cranberries, report, 836.
  - and insecticides, notes, 533, 684.
  - beneficial, protection from DDT, N.C. 702.
  - bioclimatics, 169.
  - chitinous cuticle, correlation with sensitivity to DDT, 529.
  - collection and preservation, U.S.D.A. 830.
  - community on perennial peppergrass in southern New Mexico and southwestern Texas, 830.
  - control, research progress reports, U.S.D.A. 142.
  - control with DDT, 366.
  - correlations of flight and vision, 78.
  - correlations of wings and ocelli, 78.
  - distance dispersion rates, 208.
  - effects—
    - of fabrics impregnated with DDT, 85.
    - variations in atmospheric pressure, 685.

## Insect(s)—Continued

- egg, waterproofing mechanism, 352.
- fauna of Swedish potato fields, and role as vectors of virus diseases, 211.
- flying, control by insecticidal mists, I, spray testing chamber, design, 356.
- flying, effect of insecticidal mists, factors influencing, II, 528.
- influence of soil minerals, 532.
- metamorphosis, concealed phases, 685.
- nutrition, folic acid, importance, 685.
- of Connecticut, guide, VI, mosquitoes, 366.
- pests—
  - DDT control, research progress in co-operative project, 79.
  - of animals and man, DDT tests summarized, 85.
  - of cotton, status and control in Lower River districts of Nyasaland, 535.
  - of Cuba, catalog, 532.
  - pollinators of alfalfa in California, 535.
  - population problems, incomplete block experimental designs for, 77.
  - relations to weather, discussion at joint meeting, in London June 20, 1945, 780.
- repellent(s)—
  - Indalone as influenced by sunlight, 4.
  - new German synthetic, 80.
  - No. 612, trials with, 80.
  - properties of 2-ethylhexanediol-1,3, 79.
  - responses to colors, 331.
  - vectors of virus diseases of plants, Hawaii 820.
  - vegetable garden, handbook, U.S.D.A. 505.
- Insecticidal—
  - mists, control of flying insects, I, spray testing chamber, design, 356.
  - mists, effect on flying insects, factors influencing, II, 528.
  - resin of yam bean, constituents, 9.
  - sprays, investigations, 337.
- Insecticide(s)—
  - analyses, 1945, Maine 201.
  - and insects, notes, 684.
  - application relations to leaf areas, 78.
  - chlorinated-hydrocarbon tested as, 79.
  - concentrated, dispensing, sprayers, 831.
  - contact, mode of entry, 78.
  - DDT content, determination, 778.
  - DDT, more research needed, N.Y. State and Cornell 338.
  - Euphorbia* spp., extracts as, 80.
  - German, evaluation, 222.
  - materials of vegetable origin, quarterly bibliography, No. 32 (July-December 1945), 222.
  - new—
    - German synthetic, 80.
    - six, use, 832.
    - use in dairy plants, 840.
  - organic thiocyanates in, assay, 14.
  - penetration through insect cuticle, 222.
  - research, 1943-45, notes, 533.
  - sold during 1945, analyses, N.J. 816.
  - synergistic action of N, N-diethylperonylamide with marc against Mexican bean beetle, 81.

## Insemination, artificial—

- cows, techniques, 42.
- dairy cattle—
  - developments, 800.
  - directions, Mo. 98.
  - influence of age on breeding efficiency, 496.
- intracervical and intrauterine, comparison, 800.
- Merino sheep, book, 187.
- practicality in dairy-cattle breeding, 42.
- studies in Colorado, Colo. 444.
- Institutional equipment, sanitization, 126.
- Insulin, protamine zinc, antibacterial activity, 313.
- Insulin-induced rumplessness of chickens, II, III, 802.
- Insurance—see *specific kind*.
- Inter-American Conference of Agriculture, third, at Caracas, Venezuela, 1945, 443.
- International Commission on Zoological Nomenclature, recent opinions, 348.
- International Institute of Agriculture, activity during the war, 1940-45, 606.
- Invert sugar, assay by copper reduction method, 15.
- Invertebrates, abundance variations in Illinois woodland, 350.
- Iodine excretion by normal human subjects, effect of temperature and potassium iodide, 741.
- Ions, inorganic, absorption, transport, and exudation by wheat seedling roots, 430.
- Ions, root-absorption, tracer elements showing, 36.
- Iowa College, notes, 607.
- Iowa Station—
  - notes, 607.
  - report, 1945, Iowa 903.
- Ipomoea lacunosa*, Duvel buried seed experiment, U.S.D.A. 201.
- Iran, alkali soils, 784.
- Iris (eye), color in Single-Comb White Leghorns, relation to egg production and mortality, 97.
- Iron—
  - absorption and utilization of ferrous vs. ferric in anemia, radioactive-isotope determination, 130.
  - availability in Hawaiian-grown vegetables, 595.
  - colorimetric determination, catechol derivative in, 152.
  - compounds, effect on iron retention and hemoglobin regeneration by anemic rats, 596.
  - content in enriched bread, assay, rapid method, 19.
  - effect on production of pigment by yeast, *Torulopsis pulcherrima*, 489.
  - ferrous and ferric, and high-lime chlorosis, relations between, 788.
  - inactivation by 2,2'-bipyridine, and effect on riboflavin synthesis by *Clostridium*, 31.
  - pentacarbonyl, as antiknock agent in alcohol motor fuels, 165.

- Iron—Continued  
retention by anemic rats, effect of iron compounds, 596.
- Ironing—  
fatigue, relation to posture, 285.  
surface height, effect on worker, [N.Y.] Cornell 751.
- Irradiation, biological action, 606.
- Irrigation—  
companies in Utah, activities and needs, Utah 583.  
developments in Arizona, Ariz. 111.  
ditches, small, linings, 400.  
furrows, small, soil erosion, Utah 570.  
headgate frame, practical, inexpensive, and easy to make, Colo. 253.  
under sub-humid conditions, benefits, 724.
- Ischnolaclaps* and *Atricholaclaps*, notes, 701.
- d*-Isoascorbic acid, antioxidant, 124.
- d*-Isoascorbic acid, fatty acid monoesters in fats and oils, assay, 19.
- Isocitric acid, synthesis, 766.
- Isoelectric point of viruses, determination by stain technique, 59.
- Isoleucine, effect on tobacco seedlings, 213.
- Isoleucine, necessity for supporting normal hematopoiesis in addition to globin, 737.
- Isopropyl formate, fumigants for dried packaged fruit, 77.
- Isotope, radioactive, iron absorption in anemia determined by, 130.
- Itaconic acid—  
fermentation process, 163.  
in fermentation liquors, determination, 302.
- Itaphila*, new species, Nearctic, with keys, 534.
- Ixodes ricinus*—  
control by DDT, 701.  
ecology, 230.  
water balance, 229.
- Jack fruit (*Artocarpus integrus*), planting in Coconut Grove, Fla., 667.
- Jamaica—  
banana leaf speckle, 519.  
coconut palm disease, 519.  
*Phonimya hirsuta* n. sp., 228.
- Japanese beetle—  
abundance and injury on sweet corn, N.Y. State 361.  
attractants, with special reference to caproic acid and phenyl ethyl butyrate, 687.  
bait, geraniol-eugenol content modified, 81.  
destruction by wheel bug, 355.  
ethylene dibromide as fumigant for, 77.  
larvae, milky disease, 354.  
parasites, competition, 221.  
populations, milky disease, development rate, 687.  
studies, 352.
- Jar rings, sealing qualities, testing, 882.
- Jelly making in home, use of polyphosphates, 883.
- John's disease—  
serological diagnosis in sheep, 393.  
vaccination trials against, 103.
- Joint U.S.D.A.-Land-Grant College Policy Committee, notes, 760.
- Juncaceae, *Sclerotinia* spp. on, taxonomic study, 33.
- Jute, photoperiodism in Bengal, 493.
- Kaloterms nigritus* n. sp., from Guatemala, description, 838.
- Kale—  
ascorbic acid content, effect of storage, Del. 895.  
carotene content, availability, 598.  
dehydration, 270.  
frozen in field, vitamin content, 413.  
nutritive value, influence of supplementary calcium and magnesium fertilizers, 413.
- Kansas College notes, 144, 445.
- Kansas Station—  
notes, 144, 445.  
publications available, Kans. 444.
- Karrnia paradoxus* n. gen. and sp. from S. Africa, 80.
- Karyotype evolution, cytogenetic study of *Oreopsis* spp. and interspecific hybrids, 649.
- Koifera penicillo* n. sp., on eggplant, 225.
- Kenaf, fiber yield, influence of planting time and spacing, 197.
- Kenaf, seed yield, influence of planting time and spacing, 197.
- Kentucky Station, report, 1945, Ky. 905.
- Kelonemia, in ewe and heifer fetuses, 100.
- Ketosis—  
comparison with milk fever, 854.  
in dairy cattle—  
experimental, 560.  
practical discussion, 560.  
studies VII and VIII, 239.  
in Hawaiian Islands, 239.
- Kidneys, chick, excessive ingestion of salt, effects, 105.
- Kiln, charcoal, made of cinder-concrete blocks, Conn. [New Haven] 572.
- Kitchen, planning, Iowa 285.
- Kitchens, farm, fifty, 285.
- Kok-saghyz seeds, germination, effect of alkali, comparison with common dandelion, 643.
- Kok-saghyz yellows, identification with aster yellows, and relation to big bud in tomato, 210.
- Labops*, damage to range grasses, 77.
- Labor—  
changes on cotton farms in Arkansas, 1939-44, Ark. 866.  
emergency needs during war, farmer co-operation, Mich. 732.
- farm—  
efficiency, improvement, Mich. 263.  
report (1944), Mich. 111.  
research progress reports, U.S.D.A. 149.  
requirements for California crops, major seasonal operations, 1945, Calif. 406.  
saving through farm job analysis, II, hay harvesting, Vt. 728.
- Laborers, farm, war relocation, Ohio 732.
- Laboulbenia formicarum*, ant. hosts, 221.
- Lactation, dairy cows, references to literature of 1940-43, 552.

- Lactic acid bacteria, formation of carbon dioxide, and cultural method of detection, 553.
- Lactic acid, methyl lactate prepared by alcoholysis of polymers, 146.
- Lactobacilli, cultivation, readily prepared medium, 553.
- Lactobacillus*—  
*arabinosus*—  
 17-5, pantothenic acid, microassay by, 160.  
 biotin assay, growth stimulants, 429.  
 strains, utilization and synthesis of tryptophane, 593.  
 use in microbiological assays by means of charcoal-treated peptone, 616.  
*bulgaricus* incubated at various temperatures, influence of yeast extract, 553.
- casei*—  
 factor, incubation, with chick liver, formation of folic acid, 616.  
 factor, relation to vitamin M, 748.  
 flavin adenine dinucleotide utilization by, as influenced by riboflavin analogs, 179.  
 riboflavin utilization by, as influenced by riboflavin analogs, 179.  
*helveticus*, effect of unsaturated fatty acids, 295, 553.
- $\beta$ -Lactoglobulin—  
 electrophoretic at neutrality of heat denaturation, 292.  
 empirical formula, 2.  
 systems,  $\kappa\phi$  values from electroviscosity data, 467.
- Lactose in binary mixtures, estimation, 304.
- Laelaps aplodontiae*, n. sp., new mite from *Aptodontia*, description, 369.
- Lambs—  
 enterotoxemia, control by alum-precipitated toxoid, 855.  
 enzootic staphylococcal infection—  
 associated with tick bite, I, 246.  
 associated with tick bite, II, bacteriology, 563.  
 fattening in Montana, Mont. 375.  
 feeding—  
 dehydrated potatoes and alfalfa silage, Colo. 375.  
 experiments, [N.Y.] Cornell 843.  
 sulfur, results, Colo. 856.  
 hookworm pathogenicity with adequate diet, 563.  
 infectious enterotoxemias in Colombia, 104.  
 production and feeding in El Paso Valley, 547.  
 range—  
 heritability of face covering and neck folds, evaluation, 325.  
 heritability of type and condition, evaluation, 42.  
 weanling traits, effects of environmental factors, 801.  
 scouring due to tapeworm infestation, control by lead arsenate, 856.
- Lambs—Continued  
 stiff, treatment with vitamin E, 855.
- Lamophloeus minutus*—see Flat grain beetle.
- Land—  
 agricultural, ownership and operation in southern San Joaquin Valley, U.S.D.A. 260.  
 American, abuse and conservation, U.S.D.A. 311.  
 classification, economic—  
 Botetourt County, Virginia, Va. 260.  
 Culpepper County, Virginia, Va. 260.  
 Fluvanna County, Virginia, Va. 260.  
 Greene County, Virginia, Va. 260.  
 Shenandoah County, Virginia, Va. 260.  
 Virginia counties, Va. 260, Va. 582, Va. 728.  
 farm—  
 abandoned, reseeding, grasses and cultural methods in Idaho, Idaho 654.  
 classification for tax purposes, technique, Md. 868.  
 development and economics in north-eastern Minnesota, Minn. 114.  
 of high and low productivity, price tendencies, Ohio 727.  
 forage, utilization in northeast region, longtime adjustments, 728.  
 ownership trends in North Dakota, 1929-44, N.Dak. 867.  
 physical conditions in South Carolina, Anderson County, U.S.D.A. 784.  
 range—see Range land.  
 tenure in Arkansas, IV, labor changes on cotton farms, 1939-44, Ark. 866.  
 use—  
 and financing of local government institutions in nine Vermont towns, Vt. 733.  
 effect on hydrology of soil, apparatus for recording, 108.  
 effects of soil properties in West Virginia, W.Va. 476.  
 in America, history, book, 26.
- Lantana* poisoning in cattle, 855.
- Lard—  
 production, relation to feed consumption, U.S.D.A. 725.  
 stability, effect of deodorization and antioxidants, 456.  
 stability, improvement by addition of vegetable oils, 457.
- Lateropeltis bambusarum* n. gen. and sp., ascarpic stage of fungus, 679.
- Lathyrus sylvestris wagneri* forage, digestibility and composition at growth stages compared, 91.
- Latin America, directory of agricultural periodicals, societies, experiment stations, and schools, 911.
- Lauraceae, powdery galls, 681.
- Lawn(s)—  
 European chafer, control, N.Y. State and Cornell 360.  
 home, building and care, Iowa 507.  
 planting and care, N.J. 507.

- Lawn(s)—Continued  
weeds—  
control by new acid as supplement for fertilizer, [N.Y.] Cornell 814.  
destruction by 2,4-D, N.J. 504, 813.
- Laying cages, feeding and management, N.Mex. 706.
- Laying house, utilization, Mich. 705.
- Lead arsenate—  
control of codling moth, ingredients and dosage, Va. 694.  
control of scouring caused by tapeworm lambs, 856.  
removal of sheep tapeworm, *Moniezia expansa*, preliminary report, 564.  
spray stickers for fruit trees, Conn. [New Haven] 531.  
treatment for sheep tapeworm, Miss. 717.
- Lead—  
arsenate-phenothiazine and DDT sprays, Pa. 531.
- Lead poisoning of cattle, 245.
- Leaf(ves)—  
analysis, plant-physiological method of determining fertilizer needs of soil, bases, 321.  
geotropic reaction and content of growth hormone in plants, 319.  
growth, physiology studies, II, 318.  
heat-resistance on cotton grown on saline soils, 36.  
metabolism in starving oats, 184.  
roll, natural spread, resistance of potato seedling varieties, 825.  
root formation in cuttings in relation to, 35.  
spots of grains and grasses in northern Great Plains and Western States, U.S.D.A. 821.  
tissue, analysis by micromethods, 301.
- Leafhopper(s)—  
alfalfa resistance, correlation with carotene content, 193.  
control by DDT dust, on snap beans, Mich. 360.  
new species, descriptions, 221.  
nonspecific transmission of California aster yellows virus, Calif. 363.  
six-spotted, control by DDT, 357.  
transmission of papaya bunchy top, P.R.U. 217.  
vectors of California aster yellows virus, Calif. 363.  
vectors of virus causing Pierce's disease of grapes, 828.
- Leather, mold growth, 900.
- Legume(s)—  
diseases new to Oklahoma, U.S.D.A. 57.  
effects on corn yield, La. 194.  
forage, spring-flooding effects, 192.  
hay and pasture, research summary (1902-45), Alaska 190.  
nitrogen conservation, influence of—management, 27.  
time and plowing under, 191.
- Legume(s)—Continued  
nodule(s)—  
formation, factors influencing, 34.  
formation influence nitrogenous compounds, 34.  
nitrogen-fixing capacity as shown by pigments, 34.  
pigments, 34.  
seed production, honeybee role, Mich. 88.  
seeds, dried, riboflavin, niacin, and thiamine content, 428.  
spouts, dietary substitute for fresh vegetables, 266.  
virus diseases, 210.
- Leguminosae, mosaic, 210.
- Lemon(s)—  
botrytis mold in Ventura County, 347.  
botrytis rot, effect, 347.  
organic acids, 54.  
storage changes, influence of air circulation and ventilation, U.S.D.A. 54.
- Lemongrass oil, production in Guatemala, U.S.D.A. 667.
- Lentin in veterinary medicine, 388.
- Lepidoptera types, photography, 221.
- Lepomis machrochirus*—see Bluegill.
- Leptospira*, association with contagious disease of cattle, 561.
- Leptopyga minor*—see Ash lace bug.
- Lespedeza—  
anthracnose, cause and symptoms, 671.  
culture and utilization, U.S.D.A. 197.  
*cuneata*, crossing (natural) and segregation in, 198.  
*intermedia*, Duvel buried seed experiment, U.S.D.A. 201.  
new species and one new variety, noteworthy Asiatic, 484.
- Lesser grain borer, oviposition, influences, 226.
- Lestiphorus*, North American species, taxonomic study, 353.
- Lettuce—  
big-vein disease, U.S.D.A. 215.  
response to fertilizers, Ariz. 665.  
tipburn, effects of maturity, temperatures, and soil moisture tension, [N.Y.] Cornell 215.
- Leucine, content in proteins and foodstuffs, 1.
- Leuconostoc mesenteroides*—  
amino acid requirements, 14.  
assay of *p*-aminobenzoic acid, 622.  
protein hydrolysates with, histidine determination, 618.
- Leutenizing hormone, ovarian effects on chicks and hens, 189.
- Levulose, assay by copper reduction method, 15.
- Libellulidae, distribution and seasonal abundance in Indiana, 80.
- Lice—see also Cattle lice.  
body, control by methyl bromide, 365.
- Light—  
artificial, effect on egg production of late-hatched pullets, N.Dak. 379.

- Light—Continued  
in pine production, 333.  
intensity, influence on ovulation in turkeys, 710.
- Lighting—  
farmstead, planning, 257.  
poultry for egg production, Wash. 705.
- Lignin, agricultural waste investigations, 308.
- Ligustrum lucidum*, mitosis-respiration correlation in, 37.
- Ligyrus burmeisteri*, pest of cultivated plants in Argentina, 687.
- Lily—  
bulbs—  
*Colletotrichum illi* in, eradication, 347.  
forcing after treatment for nematode control, 218.  
plantain, seasonal changes in biological equilibria, 519.  
weevil, potentially serious pest in Pacific Northwest, U.S.D.A. 364.
- Lime—  
agricultural, products, inspection, season 1945, Mass. 790.  
chlorosis due to, in Idaho plants, Idaho 58.  
effect on plants grown on acid soils, comparison with gypsum, 787.  
requirements of cotton related with peanuts, 807.  
resources, production, marketing, and use in U.S., U.S.D.A. 632.
- Limestone—  
phosphorus determination, photometric method, 151.  
plant nutrition, influence of coarsely vs. finely ground, 183.
- Linebreeding farm animals, progress report, 373.
- Linoleic acid, autoxidation, factors influencing, N.Y. State 147.
- Linseed—  
oil, fatty acid composition, relation to iodine number, 463.  
shortening, flavor reversion, elimination by heat polymerization and segregation of oil, 611.
- Lipide(s)—  
amine-aldehyde products in dehydrated egg, determination, 775.  
composition of rat, influence of age and diet, 738.  
composition of rat tissues, effect of growth, 738.  
in honey bee control central nervous system, 230.  
yeast from soils producing, 25.
- Liponyssus—  
*bacoti*, ecto-parasite of laboratory animals and control, 522.  
*geomydis* n. sp. from pocket gopher, description, 369.  
*sylvianum*, control by DDT, 544.
- Lipotropism and growth, I, dietary requirements of methionine, cystine, and choline, 738.
- Lipovitellin, egg yolk lipoprotein, preparation, 609.
- Lipoxidase, purification, decolorization test, and activator, 614.
- Listerella monocytogenes*, goat infection, clinical and laboratory study, 104.
- Liver(s)—  
coccidiosis prevented by sulfasuxidine, 387.  
fat, effect of dietary proteins and amino acids, 737.  
fatty, in rats, resistant to action of choline, dietary production, 594.  
flake, common, removal from sheep by hexachlorethane-bentinite suspension, 856.  
telang, nutritional value, 423.
- Livestock—see also Animals; specific kinds.  
breeding, progress report, U.S.D.A. 41.  
cobalt deficiency disease, in Australia, 169.  
diseases, research progress reports, U.S.D.A. 99.  
feeds, green supplements in, 90.  
pests, control by DDT, 839.  
poisoning by—  
*Crotalaria spectabilis* in Louisiana, 241.  
*Phyllanthus*, 101.  
sulphur in combination with protein concentrates, 854.  
production—  
principles book, 89.  
research progress reports, U.S.D.A. 90.  
pure breeds, gene frequency changes caused by chance, 799.
- Livestock-judging courses, examination, 410.
- Living conditions, rural—  
construction of opinion scales, [N.Y.] Cornell 119.  
opinions of university women, [N.Y.] Cornell 119.
- Loader, field, one-row mechanical for sacked potatoes, N.Dak. 722.
- Loan performances on low income farms in Massachusetts, Mass. 406.
- Locker plants—see also Food(s), frozen.  
frozen-food, community, processing instructions, 271.  
frozen-food, sanitization, 127.
- Locust(s)—  
Australian plague, outbreak areas and years, ecological characteristics, 352.  
campaign, use of transport and poison bait, 533.  
in Western Australia, 686.  
*Karrua paradoxa* n. gen. and sp. from S. Africa, 80.  
swarms, note, 80.
- Locusta migratoria*, swarms, note, 80.
- Loganberry, dry berry disease, blackberry leaf mite role, 77.
- Lonchocarpus*—  
comparison, toxicological, with *Derris*, 832.  
rotenone test, 14.
- Long-horned beetles of Ohio, identification, 831.

- Longistriata caudabullata* n. sp., new nematode from short-tailed shrew, 683.  
 Loose smut—see Smut, loose.  
*Lophortyx californica*, management in California, Calif. 76.  
*Lotus*—  
   *corniculatus*—see Trefoll, birdsfoot.  
   spp., self- and cross-fertility relationships, 185.  
 Louisiana Station—  
   notes, 445.  
   report, 1945, La. 906.  
 Louisiana University, notes, 445, 607.  
 Louping-ill, studies, I, cultivation of virus in vitro, II, pathogenic properties of culture virus, 393.  
 Louse powder of British Army, original, A.L. 63, 543.  
*Lucilia cuprina*, copper distribution and content, 541.  
 Lupines, blue, emergence and survival, effect of planting depth, 513.  
 Lupines, sweet, in U.S., preliminary information, 660.  
*Lupinus albus*, growth as influenced by sulfonamides and para-aminobenzoic acid, 183.  
*Lupinus albus*, stem tips and subjacent regions, development in sterile culture, 641.  
*Lygus*—  
   bug injury of lima bean in California, 675  
   bugs, seed pitting of lima bean, 691.  
   effect on alfalfa seed production and control by burning, 224.  
 Lymphadenopathics, canine neoplastic, 103.  
 Lymphocytoma in cow, 387.  
 Lymphomatosis in fowl, transmission, 567.  
 Lyophil process, yeasts preserved two years by, viability, 321.  
 Lysine, bloussay by use of mutant of *Neurospora*, 620.  
 Lysine, in protein hydrolysates, microbiological assay, 15.  
 Machinery—see also specific kinds.  
   for control of apple scab, 827.  
   luymaking, in western Nevada, Nev. 573.  
   rotary tillage—  
     beginnings, 571.  
     use, 571.  
 Machines for grass seed harvesting, cleaning, and processing developed by S.C.S. of U.S.D.A., Okla. 723.  
*Macracanthorhynchus hirudinaceus* in Sciuroidae, new records, 522.  
*Macrocentrus ancyliovorus*—  
   cocoon, separation from tuber worm pupae, factors, 535.  
   sex ratio, control, 835.  
*Macrophoma zeae*, as *Physalospora zeae* stage, 65.  
*Macrosporium* sp., cause of seedling disease of flax, N.Dak. 210.  
 Magnesium—  
   chemical relationship to potassium in organic and sandy soils of Florida, 787.  
   content of meals, 272.  
   deficiency, peanuts, associated with leaf-spot, 339.  
   specificity for growth of *Aspergillus niger*, 644.  
 Magpie, blood parasites of eastern Washington, 525.  
 Maine, climatic divisions, 474.  
 Maine Station, notes, 288.  
 Maine University, notes, 288.  
 Maize—see also Corn; *Zea mays*.  
   diploid and tetraploid, pollen tube establishment, comparative rates, 798.  
   ear, study methods, 323.  
   growth, indeterminate, inheritance, 649.  
   in Mexico, preliminary survey, 658.  
   seeds, electromotive forces, growth correlates, 640.  
*Malacosoma disstria*, diapause and egg hatching, Minn. 225.  
 Malaria(s)—  
   and *Anopheles*, in Northwestern States, 86.  
   avian—  
     *Aedes lepidus* as vector, 87.  
     nutrition studies III, IV, 248.  
     streptomycin effects, 107.  
     chemotherapy, study by means of yellow-fever mosquito, 227.  
     chicken, increased parasitemia following X-irradiation, 249.  
   control—  
     brief contributions on, 86.  
     by pyrethrum spraying in India, 698.  
     in Tennessee Valley, water level relationships of plants, 541.  
   imported, transmission by California anophelines, 228.  
*Mallophaga* on rodents, descriptions, 88.  
 Malt, barley, amylase content, determination, modified methods, 473.  
 Malt, for alcohol production from wheat, evaluation, 166.  
 Maltose—  
   assay in presence of glucose, 16.  
   values, effect of wheat variety, 813.  
 Mamey seed, insecticidal principle, chemical nature, 296.  
 Mammals—  
   helminth parasites in western Massachusetts, 830.  
   of Northern Great Plains along International Boundary in Canada, 682.  
   plague distribution in United States, 350  
   small—  
     censuses in Wisconsin, 75.  
     population measurement, analysis of methods, 520.  
   Welaka, Putnam County, Florida, 219.

- Mammary gland**—  
 bovine, penicillin (infused) effects, 102, 392.  
 thiouracil effects in rat, 46.  
 tissue, carbohydrate metabolism in vitro, II-III, 383.
- Mammillaria** handbook, with descriptions, illustrations, and key to species, Cactaceae, 484.
- Manganese**—  
 assay of large amounts, modified persulfate method, 12.  
 deficiency in plants, detection by tetramethyldiaminodiphenylmethane, 509.  
 intake, influence on urea excretion, 887.  
 supplement for high wheat poultry rations, 708.  
 toxicity affecting crops on acid soils, 509.
- Mango(es)**—  
 ascorbic acid content, relation to variety, 747.  
 Haden, flower formation in axillary buds, inhibiting effect of terminal bud, 493.  
 vapor-heat treated, Mexican fruit fly mortality, 84.
- Manihot utilisima***—see Tapioca.
- Mannitol**, presence, titration of boric acid, 300.
- Manostat** fluids, di- and triethylene glycols, 770.
- Manure(s)**—  
 cow, effect on egg production and hatchability, 95.  
 effect on crop yields and composition, 173.  
 losses on Colorado farms, reduction, Colo. 177.
- Maple**—see also Sirup, maple.  
 cream, preparation factors, N.Y. State 413.  
 sugar, sap-flow mechanism, 36.
- Mares**—  
 brood, infectious anemia, 719.  
 infectious abortion, etiology, 719.
- Margarine**, butterfat vs., in Sherman diet B, effect on growth and reproduction of rats, 129.
- Marine**—  
 cables, bacterial corrosion, prevention, 32.  
 microbiology, book, 30.  
 organisms, sedentary, attachment and growth, season at Lamoine, Maine, 351.
- Marketing**, experimental, of strawberries and peaches, Ohio 816.
- Marmalade**, ascorbic acid retention during preparation and storage, 432.
- Marmor**—  
*laesiofaciens*, purification and crystallization, 71.  
*phaseoli*—see Bean mosaic virus, common.
- Marsh**, salt, drainage by pump installation, 86.
- Maryland Station**, notes, 288.
- Maryland University**, notes, 288.
- Mash**, conversion to gallonage of "percentage concentration" of beer or, 166.
- Masonry**, handbook, 108.
- Massachusetts College**, notes, 445.
- Massachusetts Station**—  
 notes, 415.  
 report, 1945, Mass. 437.
- Mastitis**—  
 bovine—  
 intramammary therapy, 391.  
 staphylococcal, use of penicillin in peanut oil with beeswax, 561.  
 studies, III, penicillin therapy in streptococcal mastitis, 391.  
 treatment with penicillin, 561.  
 caused by injury, 717.  
 control—  
 by penicillin, 245.  
 informative account, 103.  
 plan in Tennessee, 392.  
 detection in New Zealand dairy herds, V, 244.  
 infectious, study I, Penicillin as therapeutic agent, 244.  
 penicillin—  
 dosages, 855.  
 therapy, 854.  
 staphylococcal, effect on plate counts of milk, 98.  
 streptococcal—  
 penicillin therapy, 391.  
 review of literature, 392.  
 treatment by intramammary infusion, concentration of penicillin in fore milk following, 562.
- Mauritius**—  
 cyclones, three in 1945, effects, 476.  
 economic entomology, twenty-five years, 352.
- Mayfiles**, Florida, new species, 830.
- Meadow**, mountain, range condition in eastern Oregon and Washington, estimation, U.S.D.A. 501.
- Meals**, simple, time savers, Miss. 736.
- Meat(s)**—see Animal(s), meat.  
 canned, thermal processing, bacteriological studies, 268.  
 dehydration—  
 by drum-cabinet, retort-cabinet, and other methods, 414.  
 by vacuum-rotary, plate-vacuum, and kettle-cabinet methods, 414.  
 emergency research, processing equipment used by U.S.D.A., 414.  
 in diet of pregnant women, 885.  
 loaves, ground pork, cereal-extended, palatability, 410.  
 magnesium content, 272.  
 production and consumption in war and peace, U.S.D.A. 260.  
 products, research progress reports, U.S.D.A. 121.  
 quality in meat products, factors, 121.  
 research progress reports, U.S.D.A. 121.
- Mechanics**—  
 farm, text and handbook, 722.  
 home, handbook, 108.

- Media—  
dispenser, simple automatic, 299.  
fermented, citric acid assay in, 14.
- Medic, black, strains, ecological and morphological characteristics, 810.
- Medical care, prepayment, in Nevada County, Ark., 875.
- Medicine, veterinary, role of disinfection, I, Sterilization of surgical instruments, 386.
- Medicine Bow Mountains, ecological reconnaissance, Nebr. 219.
- Melanoplus* nymphs of Manitoba and adjacent areas, identification, 352.
- Memnoniella*, vitamin requirements, 484.
- Menopon gallinae*—see Shaft louse.
- Menthol in peppermint oil, determination with acetic anhydride and pyridine as reagent, 777.
- Menyanthes trifoliata*, *Physoderma menyanthis* parasitizing, 60.
- Mercuric naphthenates, value as wood preservatives, 519.
- Meredith's actinomycete, *Fusarium oxysporium cubense* inhibited by, 60.
- Meristematic tissue, curly-top virus occurrence, 515.
- Metabolism studies, new type glass cage, 373.
- Metallic elements in food and feces, spectrographic determination, 304.
- Metalworking, handbook, 108.
- Metamorphosis of insects, concealed phases, 685.
- Meteorological—  
installations, radio-interference reduction, 166.  
series, periodicity, evaluation, 309.
- Meteorology—  
dynamic, textbook, 308.  
of Columbia, yearbook 1937-43, 23.  
punched cards, early uses, 629.  
teaching in colleges and universities, 308.
- Methionine—  
determination—  
by differential oxidation, 773.  
by rapid procedure, 301.  
in proteins and foods, 773.  
in chick rations, growth response to, 94
- Methyl—  
acetoxypropionate, methyl acrylate prepared by pyrolysis of, 146.  
acrylate, preparation by pyrolysis of methyl acetoxypropionate, pressure effects, 146.  
bromide—  
control of European corn borer at low temperature, 356.  
delousing agent, 365.  
determination by modified ethanolamine hydrolysis method, 152.  
fumigant, tolerance of citrus fruits, Calif. 538.  
fumigation chamber, construction and operation, Ala. 684.  
groups, carbon-linked, assay, 14.  
lactate, preparation by alcoholysis of lactic acid polymers, 146.
- Methyl—Continued  
oleate—  
catalytic air oxidation, 4.  
polymers, characterization, 4.  
purification for use as chemical intermediate, 463.  
12-hydroxy-9,10-octadecenoates, anomalous behavior in rapid iodine number determinations, 772.  
vinyl ketone from methylvinylcarbinol, 767.
- Methylene blue reduction by raw milk, influence of time and storage temperature, 713.
- N<sup>1</sup>-Methylnicotinamide—  
chemical determination and urinary excretion, 159.  
estimation, rapid field method, 624.  
excretion by normal individuals, 430.  
fate in man, 745.
- Methylvinylcarbinol, methyl vinyl ketone from, 767.
- Mexican—  
bean beetle, control by Dithane, 81.  
bean beetle, control, synergistic action of N,N-diethylpiperonylamide and pyrethrum marc in, 81.  
fruit fly, in mangoes, mortality in vapor-heat treated, 84.  
leafhopper, *Oostamia venosa* n. g. and n. sp., description, 534.
- Mexico—  
cooperation with U.S. in control of pink bollworm of cotton, 535.  
flag smut of wheat, 511.  
maize, characteristics, 658.
- Mice—  
adult female, mitotic activity, relation to oestrous cycle, 652.  
agouti series, "snow belly" double allele in, genetic analysis, 44.  
field, in mixed prairie in Kansas, 220.  
races produced by selection, growth and rates compared, 188.  
resistance, genetic, to mouse typhoid, irradiation effects, 497.  
typhoid, genetic resistance, physical basis in constitution of liver and spleen, 326.
- Michigan College, notes, 288, 445, 607.
- Michigan Station, notes, 288, 445, 607.
- Microbiological assay, of—  
amino acids, 14.  
lysine in protein hydrolysates, 15.  
tryptophan in blood, 15.
- Microbiology, marine, book, 30.
- Microclimatic factors, sampling methods, design and analysis, 628.
- Micrococcus lysodeikticus*, oxidation of acetyl phosphate and other substrates, 464.
- Micromonospora propionici* n. sp., cellulose-decomposing, from termites, 31.
- Micro-organisms—  
effect on soil aggregation, 171.  
gram-positive, effect of unsaturated fatty acids, 295.

## Micro-organisms—Continued

- growth factors, 157.
- resistance of treated cotton fabrics, 604.
- sterilization methods, 99.
- sucrose synthesis and utilization, mechanism and significance, 31.
- sugar utilization, rare forms, 178.
- thermal death points, relation to pasteurization time, Mich. 99.
- vitamin B complex in, 157, 158, 159.
- vitamin B<sub>6</sub> group, 157, 158.
- Microphallus* sp., on raccoon, 682.
- Microphotography, aid to identification of trombiculine larvae, 355.
- Microscope—see also Ultramicroscope.
  - multiple light source, 755.
  - techniques of use, book, 11.
- Microscopy, electron, shadow-casting technique, 757.
- Microspheera alni*—
  - conidial germination, mechanism, 61.
  - two new species in China, 209.
- Middle East—
  - agricultural development, report, 911.
  - rural education and welfare, 876.
- Midges, Iowa, life histories and ecology, I, *Tanytarsus*, 534.
- Migration, trans-Gulf, evidence, 522.
- Migratory locust, note on swarms of, 80.
- Mildew—
  - downy, resistant cucumbers, development, S.C. 815.

## powdery—

- fungi, conidial germination, mechanism, 60.
  - fungi of China, taxonomy, 209.
  - of broad bean, caused by *Erysiphe polygoni* in Yunnan, China, 337.
  - of cantaloups, fungicidal control Calif. 343.
  - perithecia on zinnia seed, 347.
  - resistance of textiles, 899.
- Milk—see also Pasteurization.
- and egg dehydrated mixtures, keeping quality, 415.
  - bottles, square and round, cleansing, 239.
  - butterfat content, variation, causes, 714.
  - colostrum, vitamin contents in cow and ewe, 98.
  - condensed—
    - and milk powder, book, 558.
    - sucrose and lactose content, 304.
  - costs of production in N. E. Mississippi, Miss. 870.
  - deaeration, effect on oxygen, vitamin C, and oxidized flavors, 555.
  - diacetyl production by betacocci, effect of acidity, 554.
  - dried, bacterial counts, stain for direct method, 11.
  - dried—
    - containers, packed in nitrogen, oxygen content, 386.
    - research, 557.
    - enzyme, light-sensitive, 239.

## Milk—Continued

- evaporated, storage effects on acids and formal titrations, 7.
- fall shortage, problem in price adjustment, [N.Y.] Cornell 730.
- fat—
  - autoxidation rate in different oxygen concentration, 384.
  - fractionation from solvent at low temperatures, 457.
  - glycerides, distribution pattern of fatty acids, 384.
  - nutritional studies, I, II, feeding glycerides to rats, 555.
- fever, comparison with ketosis, 854.
- films, detergents and procedures, measurement of detergency functions by washing machine, 851.
- flavor—
  - judgments, time required, 851.
  - "oxidized" and "goaty," effect of cod-liver oil, 554.
  - oxidized, effect of deaeration, 555.
  - sediment role, 98.
- fluorine content, effect of treated drinking water, 273.
- food values under cream layer, 265.
- from quarters reacting to bromothymol blue test for mastitis, composition, 244.
- heated—
  - formic acid content, determination, 145.
  - lactic acid assay, Mich. 7.
- homogenized, contamination—
  - by raw milk, detection, Mich. 622.
  - by raw milk, tests, 851.
- human, studies, XIX-XXVII, 265.
- hypochlorite effects on bacteria and chemistry of, 8.
- keeping quality, tests, 385, 554.
- mare's, vitamin content, 240.
- market, pathogenic bacteria incidence in Cairo, 393.
- nutrients, balance in making of cheeses, and fate during ripening, 556.
- pasteurization, high-temperature short-time methods, papers listed, Mich. 90.
- powder(s)—
  - and condensed, book, 558.
  - Australian, keeping quality, 385.
- preservation, effect of—
  - penicillin, 852.
  - streptomycin, 852.
- price adjustment problem, Pa. 581, [N.Y.] Cornell 730.
- production—
  - feed cost, variation between breeds, 552.
  - six thousand pounds per acre, La., 238.
- quality—
  - control for manufacturing purposes, 851.
  - effect of route delivery, 714.
- rancidity, research since 1726, 714.
- raw, bacteriological quality, effects of transport and storage, I, 713.
- raw, reduction of methylene blue, influence of time and storage temperature, 713.

## Milk—Continued

route delivery, effect on flavor, riboflavin, and ascorbic acid content, 714.

sanitation, papers, 718.

secretion, treatise, third ed., 383.

skim, separation temperature and heat treatment, relation to keeping quality of ice-cream mix, 558.

## solids—

content in South Africa, 553.

dry, bread making quality, 411.

dry, effect on bread volume, 306.

total, calculation by Sharp and Hart equations, 617.

staphylococcal mastitis effect on plate counts, 98.

sterilization methods, 99.

supply, relation to control of brucellosis in New York State dairy herds, 716.

thiamine content, determination, simple fluorometric method, 470.

vitamin A potency in Louisiana, La. 891.

whole, powder—

compressed, studies, 385.

stability, 415.

vitamin C content—

effect of deaeration, 555.

effect of feeding cod-liver oil, 554.

Milking barn, walk-in type, Nev. 578.

Milkweed—see *Asclepias syriaca*.

Millets, as green feed supplement for livestock, 90.

## Milo—

history and evolution in U.S., 810.

laboratory and greenhouse studies, 334.

## Mineral(s)—

fluorine content, assay, 10.

in plant samples contaminated by grinding, 150.

nutrient deficiencies of citrus trees, 217.

resources, book, 143.

soil, influence on insects, 532.

supply, effect on mineral concentration and nutritional quality of plants, 632.

trace, functions, deficiencies, and excesses, book, 29.

Mink, tall mink, control by Hy-Kresol dip, 88.

Minnesota Farm and Home Science, 1946. Minn. 606.

Minnesota Fruit Breeding Station, introduction of three new fruit varieties, Minn. 331.

Minnesota Station—

notes, 144.

report, 1945. Minn. 438.

Minnesota University, notes, 912.

Mississippi Farm Research—

January 1946. Miss. 287.

February 1946, Miss. 756.

March–April 1946, Miss. 910.

Mississippi River Basin, lower, stream flow measurements, 1944, 399.

Missouri Station—

notes, 758.

## Missouri Station—Continued

report—

1942–43, Mo. 439.

1944, Mo. 439.

Missouri University, notes, 758.

## Mite(s)—

infesting fungus cultures, biology, classification and control, 698.

new *Laelaps aplodontiae*, from *Aplodontia*, 369.

on mink, control by Hy-Kresol dip, 88.

six new, of superfamily Parasitoidea, 369.

Mitosis, respiration correlation in plants, 37.

## Moisture—

absorption, measurements, accelerated method, 12.

in arid soils, effect on dissolved and exchangeable ions, 171.

soil—see Soil moisture.

stress on roots in container of saline soil, evaluation techniques, 171.

Molasses, blackstrap, constituents, isolation by chromatographic methods, 351.

Molasses-beet pulp, cattle fattening by, Wash. 91.

Mold(s)—see also *specific kinds*

bread, spores, ultra-violet irradiation, 323.

growth—

inhibitors, II, active agent responsible for inhibitory effect of propionates, 612.

on leather, 900.

relation to deterioration of corn in storage, review, 337.

## Molybdenum—

blue reaction, modified procedure, 13.

microdetermination in plants and soils, 152.

poisoning, chronic, in cattle, 393.

*Monileia expansa*, removal from sheep by lead arsenate, preliminary report, 564.

## Monkey—

antianemia factor, 600.

ascorbic acid deficiencies, 283.

riboflavin requirements, and new factor in liver, 599.

*Monochamus titillator*—see Southern pine sawyer.

Monomethylaminoethanol in diet of chicks, 549.

## Monthly Weather Review—

October–December 1945, 309.

January–March 1946, 630.

Mordellidae, monograph, 81.

Mosaic(s)—see also *specific host*.

in *Nicotiana* spp., symptoms, relation to genotype and temperature, 39.

on Leguminosae, 810.

on winter oats induced by soil-borne viruses, 338.

Mosquitoes—see also *specific name*.

adult, control in open unwooded areas by airplane application of DDT, 368.

adult, outdoor control with DDT or pyrethrum, ground equipment, 368.

- Mosquitoes—Continued  
 anopheline, female, moonlight and house-haunting habits in West Africa, 367.  
 breeding, role of aquatic vegetation, 698.  
 control—  
   brief contributions, 86.  
   by DDT emulsion to rice-field water, 540.  
   by concentrated sprays, 366.  
   by DDT, 86, 366.  
   in Connecticut, 352.  
 corpora allata, 352.  
 exposed to DDT, effect of temperature, 227.  
 larvae in rice fields, airplane spraying with DDT, 87.  
 malaria—  
   in Brazil, 87.  
   in southern Michigan, Mich. 86.  
 migration in Salt Lake City, 86.  
 nervous system, study by Dodian technique, 540.  
 new—  
   species from New Guinea, 227.  
   species from Okinawa, 87.  
   to United States, *Aedes tortilis*, 366.  
 of Connecticut, 366.  
 of Espiritu Santo (New Hebrides), bio-nomics, 367.  
 repellents, new, investigation, 228.  
 Motor fuels, alcohol, iron pentacarbonyl as antiknock agent in, 165.  
 Mouse—see Mice.  
 Mules, salmonellosis outbreak, 247.  
 Mung beans, source of protein for turkey poults, 235.  
*Mus musculus*, adult, mitotic activity, relation to oestrous cycle, 652.  
*Musca domestica*—see House fly.  
   vicina, life tables, 686.  
 Mushroom, cultivated, nutrition, 815.  
 Mustard, wild yellow, seed, concentrate for milk cows, Mont., 849.  
*Mycobacterium avium*, pseudo-mycelia developed in embryo-extract culture, 101.  
*Mycobacterium* spp., antibiotic material from *Bacillus lichemiformis* active against, 313.  
*Mycosphaerella brassicicola*, spermogonia versus pycnidia, 512.  
 Mymaridae, new genera and species, descriptions, 534.  
 Myosmine, chemical reactivity, 5.  
 Myrmecological technique, 221.  
*Myrmica brevinodis transversinodis* n. var., new house invader, description, 855.  
 Myxomycete—  
   morphogenic-movement rate, 38.  
   protoplasm, torsion, 37.  
*Myzus pseudosolani*, vector of tobacco rosette, 71.  
 Nairobi sheep disease virus, survival in *Rhipicephalus appendiculatus*, 230.  
*Najas arguta* in Central America and its relationship to *N. wrightiana*, 792.  
*Najas wrightiana*, relationship to *N. arguta*, and two new subspecies, 792.  
 Names, generic, abbreviations, 755.  
 Nantucket pine moth, informatory account, 84.  
 Naphthaleneacetic acid—  
   apple preharvest drop, effect of—  
     aerosols, 50.  
     application method, 51.  
   effect on apple fruit maturity, 50.  
 - $\alpha$ -Naphthylthiourea—see ANTU.  
 Narcissus—  
   leaf diseases, III, *Scierotinia polyblastis* on *Narcissus tazetta* var. *Soleil d'Or*, 680.  
   virus diseases, general study, 74.  
 National Advisory Research Committee, notes, 760.  
 National Poultry Improvement Plan, Directory of U.S. Register sires and dams under, U.S.D.A. 97.  
 Natural products, pyridoxamine and pyridoxal contents, 158.  
 Naval stores, water determination in, Fischer method, 150.  
 Nebraska Station—  
   notes, 445, 758.  
   report, 1945, Nebr. 907.  
 Nebraska University, notes, 445, 758.  
 Necrosis, internal, of potato tubers caused by psyllids, 513.  
*Nectria ditissima*, foci of infection on pear, 73.  
 Negro—  
   American, demographic study, 264.  
   population of Kentucky, Ky. 409.  
   rural and urban residence in U. S., 874.  
 Nematode(s)—  
   *Acrostalagmus eosporus* n. sp. parasitizing, 75.  
   cause of root nodules on zinnia, 218.  
   of carnivores, annotated list of, *Phy-saloptera*, 88.  
   parasites, Brazilian chytrids, 637.  
*Nematodius* adults, eggs, and larvae, recovery for experimental purposes, 717.  
 Neo- $\alpha$ -carotene B, stability and activity, 615.  
 Neo- $\beta$ -carotene B—see also  $\beta$ -carotene.  
   stability and activity, 615.  
 Neo- $\beta$ -carotene U, vitamin A activity and its steric rearrangement in digestive tract of rats, 743.  
*Neolithobius*, new species, description, 351.  
 Neoplasma, canine lymphadenopathic, 105.  
 Neoplastic disease of fowl, with special reference to history, incidence, and seasonal variation, 396.  
 Nervous tissues, as influenced by deficiencies of pantothenic acid vs. pyridoxine in swine, 104.  
*Neurospora*—  
   choliness mutants, utilization of choline analogs, 422.  
   in microbiological assays, 20.  
   inheritance and nutritive needs in, N.Dak. 180.  
   leucineless, reverse-mutation and adaptation, 651.  
   mutant, use in bioassay for lysine, 620.

*Neurospora*—Continued

- riboflavin synthesis by, genetic differences in strains, 35.
- temperature-sensitive riboflavinless mutant, 35.
- tetrasperma* type, homothallic fungus species, maintenance of heterozygosity, 651.
- thiamine synthesis by, genetic differences in strains, 35.
- Neutron bombardment, fungus variation induced, 32.
- Nevada Station, notes, 445.
- Nevada University, notes, 445.
- New Guinea, mosquitoes, new species, 227.
- New Hampshire University, notes, 758.
- New Mexico Station, report, 1945, N.Mex. 440.
- [New York]Cornell Station, notes, 607.
- [New York]Cornell Station, report, 1945, 908.
- New York State Station, notes, 144, 446, 607.
- New Zealand—
  - sugar beet mosaic, 514.
  - whiptail control in cauliflower and broccoli crops, 512.
- Newcastle disease—
  - investigations in war research program, 567.
  - status in U.S., 720.
  - virus strain, modification by intracerebral passage through ducklings, preliminary, 721.
- Niacin—
  - content of dried legume seeds, 428.
  - retention in cooking pork and processing bacon, 428.
- Niadina jauva* n. gen. and sp., description, 686.
- Nickel deficiencies in agricultural crops, 509.
- Nicotiana* spp., mosaic symptoms in genotype and temperature relations, 39.
- Nicotiana tabacum*—see Tobacco.
- Nicotinamide—
  - excretion by normal individuals, 430.
  - methochloride and its fluorescent derivatives, 280.
  - microbiological determination, 429.
- Nicotine, penetration rates in cockroaches from solutions of various pH values, 77.
- Nicotinic acid—
  - deficiency—
    - 3-acetylpyridine producing in mice, 136.
    - corn as causal factor, 135.
    - in turkey poults, and occurrence of perosis, 253.
  - excretion by normal individuals, 430.
  - influence on response of chicks receiving diet high in corn, 549.
  - low-level diet, effects on man, 136.
  - low-level rations, folic acid importance in dogs on, 135.
  - microbiological determination, 429.
  - of fish from Michigan waters, lake herring, carp, suckers, and burbot, 744.

## Nicotinic acid—Continued

- of tea, 280.
- requirements of dog, as influenced by corn grits, 135.
- requirement of chicks, influence of gelatin and tryptophan, 549.
- retention in preparation of overseas hams and bacon, 279.
- water-insoluble esters and amides, preparation and value, 6.
- Nicotinuric acid—
  - excretion by normal individuals, 430.
  - microbiological determination, 429.
- Nigeria, Northern, bovine helminths, 245.
- Nitidulid beetle, new species, 365.
- Nitrates—
  - in plants, occurrence and assimilation, 183.
  - microdetermination, Devarda method, 151.
  - nitrogen nutrition, influence on development of hypocotyledonary buds of flax, 322.
  - utilization by coffee plant under different sunlight intensities, U.S.D.A. 203.
- Nitrites, colorimetric determination, 770.
- Nitrogen—
  - conservation in soil—
    - influence of time and plowing under legumes, 191.
  - legume management factors, 27.
  - content of leaf tissue, determination, by micromethods, 301.
  - determination by Kjeldahl method, catalytic activity of selenates in, 151.
  - effect on quality—
    - and yields of peas, N.Y. State and Cornell 330.
    - of peas, 877.
  - fertilizer—
    - effect on semiarid soil, 786.
    - for corn and oats, placement, Miss. 633.
  - fixation by soybeans, effect of straw and nitrogen, 811.
  - in pyridine ring-type compounds, determination by Kjeldahl method, 301.
  - metabolism in barley seedling, aspects, relation of early growth to, 316.
  - metabolism in corn, influence of ammonium nutrition, 794.
  - nitrous, losses from soils on desiccation, 479.
  - nutrition, in onions, influence on susceptibility to yellow-dwarf virus, 216.
  - requirement in utilization of carbonaceous residues, in soil, 480.
  - simple compounds, utilization by ruminants, 231.
- Nitrogen, soil, injury to spinach, 225.
- sources, effect on soil reaction, exchangeable ions, and yields of crops, 786.
- thiocyanate, assay in organic thiocyanates and mixtures, 14.
- Nitroparaffins—
  - amylopectin separation, 15.
  - amylose separation, 15.

- Nodule(s)—  
bacteria—  
and clover, symbiosis, genetic factors, 651.  
antibiotics from *Aspergillus wentii* against, 30.  
factors influencing root penetration, 34.  
legume, pigments in, 34.  
Nomograph for calculation of over-all heat transfer coefficients, 562.  
Nordihydroguaiaretic acid—  
antioxidant properties, 465.  
stabilization of carotene, 466.  
Norelac, new synthetic coating material, 466.  
North Carolina research and farming, 1946, N.C. 756.  
North Carolina College, notes, 446, 608, 758.  
North Dakota College, notes, 758.  
North Dakota Station—  
Bimonthly Bulletin—  
1946, N.Dak. 756.  
January–February 1946. N.Dak. 287.  
notes, 758.  
Northern feather mite, control by DDT, 544.  
Norway, deficiency diseases of cattle and sheep, therapeutic effect of small doses of cobalt, 563.  
Nutrients—  
availability, metabolic calculations reviewed, 131.  
consumption by Army students at University of Missouri, 884.  
distribution in drained and liquid portions of canned vegetables, 588.  
influence of cooking processes, N.C. 884.  
Nutrition—  
chemistry, textbook, seventh edition, 410.  
children, and chemical growth, 274.  
human goals, U.S.D.A. 140.  
infant, relations to diets of mothers, 127.  
men, field surveys, fasting, random, and oral loading tests, 624.  
microchemical methods of study, 127.  
new developments, 127.  
plant—see Plant nutrition.  
populations, V, vitamin C nutrition of rural population in middle Tennessee, 746.  
young people and their families, book, 418.  
relation to defense mechanism against bacterial infections in rats, 559.  
research—  
by experiment stations, progress reports (1945), U.S.D.A. 142.  
progress reports, U.S.D.A. 140, 141.  
surveys, symposium, 127.  
surveys, techniques, 127.  
Nutrition Foundation investigations on nutritive value and oxidative enzymes in dehydrated vegetables, 878.  
Nuts, tree, pollination, Wash. 202.  
Nuts, diseases in Oregon (1945), U.S.D.A. 58.  
*Nuttallia equi*, opossums infected with piroplasm of type of, 101.  
Nyasaland, Lower River districts, cotton insect pests, status and control, 535.  
*Nyctobia* larvae, new description, 364.  
Nylon thread, sewing, selection, Ohio 751.  
*Nymphalis californica*, flights in British Columbia and Alberta in 1945, 354.  
Oat(s)—  
*Avena* test, variability, influence of kernel size, age, location in panicle, and variety, 485.  
blight caused by *Helminthosporium* differing from cause of leaf spot, 511.  
Delta, test, time of application of nitrogen materials, Miss. 654.  
interspecific cross, inheritance of rust reactions, etc., 41.  
leaves, metabolism in starving, 184.  
new helminthosporium disease, 334.  
nitrogen fertilizer, placement, U.S.D.A. 633.  
seed-borne disease, new, [N.Y.] Cornell 824.  
spring, Illinois-adapted varieties, Ill. 198.  
utilization by market hogs, effect of fineness of grinding, 377.  
variety(ies)—  
performance tests (1945), N.C. 192.  
reactions to four races of loose smut, 511.  
studies in Tennessee, Tenn. 660.  
winter, mosaics induced by soil-borne viruses, 338.  
Oatmeal, retention of B vitamins during cooking, 599.  
Ocelli and wings correlated in insects, 78.  
*Odocoileus hemionus columbianus*, parasites, diseases, injuries, and anomalies in British Columbia, 682.  
Odonata, distribution and seasonal abundance in Indiana, 80.  
*Odontria zealandica*, control by lead arsenate, 83.  
Oedogoniaceae, from Louisiana and Texas, 180.  
Ohio River Basin, stream flow measurements, 1943, 399.  
Ohio State University, notes, 608, 758.  
Ohio Station, notes, 608, 758.  
Oil(s)—see also specific kinds.  
antioxidants, evaluation means by stability values obtained by different rapid methods, 471.  
antioxidants, fatty acid monoesters of L-ascorbic and D-isoascorbic acids, 462.  
bodies drying, analysis, 21.  
citrus volatile, assay apparatus, 10.  
content of soybeans, determination, effect of relative humidity, 469.  
crops, major, world trends, U.S.D.A. 405.  
crops, research progress reports, U.S.D.A. 140, 141.  
deterioration, problems of Army, 418.  
fatty acid monoesters of L-ascorbic and D-isoascorbic acids in, assay, 19.  
semidrying, analysis, 21.  
sesame, sesamin determination in, 155.

- Oil(s)—Continued  
 sprays—see Sprays.  
 thermal properties, I-V, 455.  
 thiocyanogen reagent and method, modified, 472.  
 vegetable—  
   extraction, continuous, countercurrent extractor, rising-film evaporator, and oil stripper, 769.  
   solvent extraction from raw materials, bibliography, 457.  
   solvent extraction, techniques, 147.  
   solvent mixtures with, densities and viscosities, determination, 147.  
    $\gamma$ -tocopherol assay in, 160.  
 Oklahoma, new publications and list of publications available, Okla. 756.  
 Oklahoma College, notes, 759.  
 Oklahoma Station, notes, 759.  
 Okra, apid-resistance, test for, 81.  
 Oleic acid—  
   adsorption analysis, technique, 155.  
   purification for use as chemical intermediate, 463.  
 Oleyl alcohol, purification for use as chemical intermediate, 463.  
 Olives, home pickling, Calif. 125.  
 Olives, processing methods, advances in California and abroad, 884.  
 Olives, Russian, new disease of unknown cause, 73.  
*Olipidium*—  
   *granulatum* n. sp., description, 637.  
   *rotiferum* n. sp., description, 637.  
 O'Neal, Edward Asbury, III, of Alabama, 757.  
 Onion(s)—see also *Allium cepa*.  
   color-inhibiting factor, relation to smudge resistance, U.S.D.A. 216.  
   diploia rot, 344.  
   investigations at Utah Station, Utah 330.  
   production, book, 815.  
   roots, camphor effects on, 183.  
   seed heads, blasting, U.S.D.A. 58.  
   smudge resistance, relation to color-inhibiting factor, U.S.D.A. 216.  
   smut, control, dust fungicides versus formaldehyde, Mich. 344.  
   susceptibility to yellow-dwarf virus, influence of nitrogen nutrition, 216.  
   thrips, control by DDT, Ohio 361.  
   varieties, reaction to yellow-dwarf virus and viruses from shallot, garlic, and narcissus, 216.  
*Onopordum acanthium*, Duvel buried seed experiment, final results, U.S.D.A. 201.  
*Oenothera biennis*, Duvel buried seed experiment, final results, U.S.D.A. 201.  
 Ontario Agricultural College—  
   and Experiment Farm, report, 286.  
   notes, 144.  
*Oodinium limneticum* n. sp., description and life history, 351.  
 Opossums, piroplasm of *Nuttallia equi* type in, 101.  
 Opsonocytaphagic test in bovine brucellosis, 102.  
*Opuntia ammophila*, fungus infestation, 680.  
 Orange(s)—see also Citrus.  
   juice—  
     canned, quality, 417.  
     organic acids in, analysis, 154.  
   navel, stubborn disease, virosis, symptoms, 828.  
   trees—  
     quick decline—see Quick decline.  
     root rot or "tristeza," 347.  
   Valencia, seed oil, 459.  
 Orchards—  
   frost damage and importance of elevation and drainage, Pa. 506.  
   Oklahoma, codling moth control, 537.  
 Orchids—  
   black rot, distribution, U.S.D.A. 58.  
   seeds, germination and development in asymbiotic media, action of thiamine, 485.  
 Orchitis in swine due to *Brucella suis*, 565.  
 Orceinol reagent, preparation, improvement, 616.  
 Organic chemical syntheses, book, 1.  
 Organic materials, hydroxyl content, determination by macro- and semimicromethods, 154.  
 Organisms, small, dispersion, 208.  
 Oriental cockroach, food preferences, 84.  
 Oriental fruit moth—  
   control by DDT and Ryanex, 604.  
   forecast for 1946, and control, N.Y. State and Cornell 834.  
*Ornithodoros delanoet acinus*, biology, 230.  
 Ornithology, economic, 522.  
*Orthopodomyia alba*, in Louisiana, 86.  
 Osteopetrosis in chickens, production by filterable agent, 396.  
 Osteopetrosis gallinarum, spontaneous, familial incidence, 715.

emergence and yield, effect of seed treatment and seeding dates, 676.  
freezing, rate, effect on appearance, palatability, and vitamin content, 880.  
fresh green, ascorbic acid content, determination, 623.  
frozen, vitamin retention in quantity food service, 889.  
quality effect of nitrogen, N.Y. State and Cornell 330, 877.  
seedlings, growth inhibition by urine extract, 639.  
starch, amylose content, 450.  
vitamin content, effect of freezing, canning, and dehydration, 891.  
weed control by chemical sprays, Mich. 49.  
weevil, informatory account, U.S.D.A. 83.  
yields, improvement by nitrogen, N.Y. State and Cornell 330.
- Peach(es)—  
bacterial spot and behavior in Delaware, Del. 678.  
blotch, symptoms, 217.  
browning, prevention by ascorbic acid, Ga. 735.  
canning, 1946 demand situation, statistics, Calif. 873.  
carotenoids, effect of processing, S.C. 891.  
cat-facing and dimpling, causes, 695.  
catalase of leaves, variations in lime chlorosis, 73.

## Peach(es)—Continued

"counter-sizer," description and operation, N.C. 577.

deformed, sucking bugs causing, control by DDT, 537.

fruitfulness relations to pollen grain morphology and physiology, Del. 52.

growth and yield as influenced by culture practices, 51.

marketing, experimental, Ohio 816.

oxidation, control, 883.

peeling, lye solutions, addition of wetting agents, S.C. 883.

production, economic study in Louisiana, La. 114.

seed, after-ripening needs by source and variety, 51.

## tree(s)—

borer control in Delaware, Del. 694.

in sand culture, tops, growth and composition, W.Va. 202.

spraying with DDT, 695.

varieties, breeding and improvement in New Jersey, N.J. 816.

vitamin C content, effect of processing, S.C. 891.

wart, transmission by graft inoculations with affected fruit tissue, 827.

## Peanut(s)—

absorption of calcium from kaolin and bentonite at varying levels of calcium, 787.

butter, improvement by changing flavor and texture, 413.

butter quality, improvement, 266.

farmers' stock, U.S. standards, analyses of peanut kernels for, 459.

kernels, analyses for U.S. standards for farmers' stock peanuts, 459.

kernels, moisture content, determination, 617.

leaf spot associated with magnesium deficiency, 339.

## oil(s)—

antioxidants, molecularly distilled, stabilizing agent for fats of poor keeping quality, 460.

hydrogenated, viscosities and densities, 460.

solvent extraction, techniques, 147.

## protein hydrates—

preparation and properties, 163.

use as tacky and remoistening adhesives, 164.

protein-solution viscosity patterns, methods and comparisons, 2.

## proteins—

color, improvement, 764.

electrophoretic investigations, I, II, 763.

seed treatment tests, 335.

## Pear(s)—

boron deficiency, symptoms and control, 678.

catalase of leaves, variations in lime chlorosis, 73.

cold storage design, 577.

## Pear(s)—Continued

nectria canker, foci of infection, 73.

organoleptic tests, 735.

production costs in Hood River Valley, Oreg. 113.

psylla control in 1945, 363.

scab, conidial pustules and role as nectria canker foci, 73.

## Pecan(s)—

effect of chloride, Okla. 204.

nut casebearer, control, timing spray applications, 538.

nutritive value, Ariz. 122.

## Pectin(s)—

alkaline de-esterification, acceleration by electrolytes, 5.

and pectinol A activities on other substances, 5.

in gel powders, dispersibility due to sugars, 413.

methyl ester content, determination, 302.

thermal degradation, 294.

Zeisel methoxyl values for, errors from retained alcohol, 154.

Pectinol A, effect on pectin and other substances, 5.

## Penicillin—

absorption, agents for delaying, efficiency, 388.

activity, relation to bacterial spores and preservation of milk, 852.

concentration in fore milk following intramammary infusion for mastitis, preliminary report, 502.

dosage and blood levels for horses, 566.

dosages for *Streptococcus agalactiae* mastitis, 855.

elaboration and liberation by *Penicillium notatum*, 483.

enzymes tested against, 32.

fermentations with *Penicillium chrysogenum* X-10—12, effect of environmental conditions, 792.

in peanut oil with 3 percent beeswax, local use in bovine staphylococcal mastitis, 561.

infused, effect on bovine mammary gland, 102.

infusion in bovine mammary gland, effects, 392.

mastitis control, 245.

microbiological aspects, IV, production in submerged cultures of *Penicillium notatum*, 636.

pharmacology, aspects, 854.

## production—

by superior strain of mold, 636.

in submerged cultures, 33, 483.

in surface cultures, 33.

role of corn steep liquor, 612.

submerged fermentation on synthetic media, metabolic changes, 314.

supplies from Wisconsin research, Wis. 314.

therapeutic value for infectious mastitis, 244.

# Penicillin—Continued therapy—

- bacterial infections, 853.
- in fatal case of equine tetanus, 395.
- in mastitis, 854.
- in strangles, 100.
- in streptococcal mastitis, 391.

## treatment of—

- bovine mastitis, 561.
- acute equine infectious anemia, 247.
- Pasteurella multocida* infection in wild ducks, 398.

Penicillin-producing strains of *Penicillium notatum-chrysogenum*, comparison, 792.

Penicillin X, production in submerged—  
culture 791.  
surface cultures, 636.

## Penicillinase—

- Bacillus cereus* producing, 32.
- bacterial, production, nature, and significance, 30.

## *Penicillium*—

### *chrysogenum*—

- strain 62078, X-ray produced mutant, desthiobiotin study, 615.
- strain X-16—12, penicillin fermentations, effect of environmental conditions, 792.
- gladioli*, metabolic product, antifungal and antibacterial, gladiolic acid, 637.

### *notatum*—

- antibiotic potency varying with strains, 180.
- bacteriostatic action in surface culture, relation to production of CO<sub>2</sub>, 636.
- cytology, 38.
- elaboration and liberation of penicillin, 483.
- penicillin production in submerged cultures, 33.
- pleomorphism, 180.
- variation induced by bombardment with neutrons, 32.
- notatum-chrysogenum*, penicillin-producing strains, comparison, 792.
- rots of citrus and apple fruits, 217.

Pennsylvania College, notes, 446.

Pennsylvania Station, notes, 446.

Peppergrass, perennial, insect community on, in southern New Mexico and southwestern Texas, 830.

Peppermint oil, menthol content, determination with acetic anhydride and pyridine as reagent, 777.

Pepsin, tyrosine iodination in, 3.

Peptone, charcoal-treated, use in microbiological assays, 616.

Perch migration, chart, 525.

Pericarp, seed relation to fruit growth and ripening, 38.

*Periplaneta americana*—see American cockroach.

Perishables—see Agricultural perishables.

*Peronosplasmopara cubensis*, cucurbit resistance to, test for, 81.

Perosis caused by feeding high levels of thiouracil, 567.

Perosis in turkey poultis, 253.

Peroxidase, efficacy in dehydration, quick test, 271.

Peru, broadbean disease due to *Phoma* sp., 671.

## Pest(s)—

agricultural, control by heat-generated aerosols, preliminary studies, 78.

control, United States patents, review, U.S.D.A. 222.

insect, of animals and man, DDT tests summarized, 85.

## Petroleum—

cooperatives, affiliated with Southern States Cooperative, Inc., delivery efficiency, U.S.D.A. 408.

delivering to farmers efficiently, U.S.D.A. 408.

oil spray deposits on citrus leaves, determination, 305.

Petunia, double fertilization in, 41.

*Peucectia vvidans*, poison-squirting, 351.

Pharmaceutical products, vitamins in, availability determination, methods, 424.

Pheasants in Wisconsin, 682.

Phenylalanine, determination by rapid procedure, 301.

Phenol, reaction with colon bacillus, temperature coefficient by new technique, 101.

Phenols, toxicity to *Colletotrichum circinans*, effect of pH, 821.

## Phenolic—

compounds, biological activity, 242.

fungicides, quantitative determination, 778.

Phenology, in British Isles (Dec. 1944–Oct. 1945), 169.

## Phenothiazine—

action on gastrointestinal strongyles of sheep, 394.

administration methods for sheep, 104.

anomalous experience, 388.

as anthelmintic, 101.

cause of abortion in sheep, 246.

control of cecal worms and blackhead disease of turkeys, limitations, 569.

efficacy in treatment of sheep for internal parasites, 246.

Phenyl ethyl butyrate, attraction for Japanese beetle, 687.

Phenylacetic acid, histological responses of bean plants, 319.

*Phialea temulentia*, blind-seed disease of grasses due to, 69.

Philippine Islands, agricultural geography, graphic summary, U.S.D.A. 262.

*Phlebotomus*, new species, descriptions, 700.

Phlepsid leafhopper vectors of California aster yellows virus, Calif. 363.

*Phlox drummondii*, developmental changes in apex of mature, 38.

Phomopsis fruit rot of eggplants, control, N.J. 676.

- Phoniomyia hirsuta*, n. sp. from Jamaica, 228.
- Phosphatase test, of Cheddar cheese, 20.
- Phosphate—  
adsorption in Illinois soils, 175.  
rock, defluorinated, phosphorus supplement to rations of dairy cattle, 712.  
soil retention, 176.
- Phosphorus—  
content of dehydrated green beans, effect of blanching, storage, and cooking, 276.  
content of leaf tissue, determination by micromethods, 301.  
determination, modified molybdenum blue procedure, 13.  
in—  
limestone, determination by photometric method, 151.  
poultry nutrition, II, 551.  
soybean oil meal, availability for rat, 596.  
soybean oil meal, utilization, enzymatic relationships, 596.  
wheat starch, extraction, 3.  
inorganic, determination in plant materials, 773.  
radioactive, absorption by barley roots, 36.
- Photocolorimetry, test, modified Kreist, 468.
- Photographs, aerial—  
specifications for forest management, 667.  
use in estimation of ground condition of vegetation, 637.
- Photoperiod—  
and flowering of plants correlated with nitrogenous food, 185.  
effect on laying hens, Fla. 96.  
relation to boron requirement of plants, 796.  
salt-resistance in cotton in relation to, 185.
- Photoperiodic response, factor in choice of plants for testing soil deficiencies, 795.
- Photoperiodism—  
and sex in *Zea mays*, 649.  
in jute in Bengal, 493.
- Phucomyces* in assay in thiamine in agar, 639.
- Phyllanthus abnormis*, livestock poisoning by, 101.
- Phyllocoptes gracilis*—see Blackberry leaf mite.
- Phyllophaga hubbelli* n. sp. from Alabama and Georgia, description, 854.
- Phymatotrichum omnivorum*, as influenced by carbohydrates and root microfloras, 65.
- Phylloptera—  
*limbata*, redescription, 522.  
of carnivores, 242.  
spp., of carnivores, annotated list, 88.
- Physalospora zeae*—  
as *Macrophoma zeae* stage, 65.  
corn ear rot due to, 65.
- Physoderma menyanthis*, life history, 60.
- Physoderma menyanthis*, parasitism of *Menyanthes trifoliata*, 60.
- Phytomonas*—  
*betae-gelatae* n. sp., cause of viscous rot of frozen beets and fructosan, 673.  
*tumefaciens*, growth substances in, 59.
- Phytolacca americana*, Duvel buried seed experiment, final results, U.S.D.A. 201.
- Phytopathogenic bacteria, mutation induced by acenaphthene, 798.
- Phytophaga destructor*—see Hessian fly.
- Phytophthora*—  
*capsici*, cause of tomato fruit rot, epiphytology and control, 345.  
*erythroseptica*, invasion of potato tuber, 513.  
*infestans*, epidemiology in potato fields, Minn. 212.
- Pickles, spicing by imitation clove oil, 267.
- Pickleworm, enemy of cucurbits, N.C. 536.
- Pig(s)—see also Hogs; Sows; Swine.  
*ascaris*, cytochrome oxidase, 387.  
breeding, feeding, and management, 375.  
cleavage and attachment stages, 325.  
fed desiccated egg white, biotin deficiency syndrome, 377.  
fed wheat and barley, protein and mineral supplements, Mont. 845.  
feeding—  
level, effect on daily gains, 845.  
on cooked potato silage, Colo. 233.  
trials, allotment for, relation to factors affecting rate of gain, 844.  
finishing on rations including barley, oats, and corn, Miss. 846.  
forage crops for, value, Miss. 233.  
gastroenteritis, transmissible, 394.  
growing, feeding irradiated ergosterol ( $D_2$ ) and irradiated 7-dehydrocholesterol ( $D_1$ ), 376.  
nutrition, nicotinic acid and level of protein intake, 375.  
placenta, histochemical reactions, 497.  
poisoning by ANTU, 854.  
roundworm, penetration of hexyl resorcinol, 242.  
treatment by sulfaguanidine for coccidiosis, 564.  
tuberculin test, 247.  
typhus caused by *Salmonella suispestifer*, Nehr. 858.
- Pigeon(s)—  
bone growth, X-ray effects, 47.  
dietary anemia, 235.  
housing, N.J. 578.  
treatise, 711.
- Piglet anemia, incidence, effect of feeding green food to pregnant sow, 233.
- Piglets, weaning at early age, 547.
- Pigment(s)—  
antibacterial, from *Fusarium javanicum*, 314.  
deposition, inhibition in incisor teeth of rats deficient in vitamin E from birth, 432.  
fluorescent, assay by fluorescence intensity, 12.

## Pigment(s)—Continued

production by yeast, *Torulopsis pulcherrima*, effect of iron and other factors, 489.

## Pine(s)—

cones, infestation by *Erechthias fulguritella*, 226.

fused needle disease, field observations, 519.

jack, budworm control by forest management, 226.

jack, natural reproduction in Pennsylvania, Pa. 205.

longleaf-slash type, glazing in, burning effects, 57.

Monterey—see also *Pinus radiata*.

increment and rainfall in Australia, 205.

pollen shed, 206.

stems, lean and ellipticity in Australia, 206.

pflion, association, vertebrate inhabitants in Death Valley region, 348.

ponderosa, second cutting cycle, 668.

production, water and light, 333.

red, thinning, ecological changes resulting, 668.

seed, viability after prolonged cold storage, 205.

slash, plantations, damage by fusiform rust, Miss. 219.

southern, bark beetles, informatory account, 84.

tip moth, informatory account, 84.

western, silviculture, entomology, 364.

white, blister rust distinguished from pflion rust in telial stage, U.S.D.A. 58.

## Pineapple—

canned, vitamin content, 742.

chemical studies, 292.

plants, nitrogenous constituents, effects of potassium, 507.

a-Pinene, thermal isomerization, continuous, in liquid phase, 296.

Pink bollworm of cotton, control, cooperation between U.S. and Mexico, 535.

*Pinus radiata* boxes for butter, experiments, 556.

Pipunculidae, genera and subgenera, types, 353.

Protoplasm, opossums infected with, 101.

*Psittacia* spp., Chinese gallnuts on, 57.

*Pisum sativum*, integument, sclereids, structural composition, 647.

Pith, new superior, for free-hand sections, 493.

Pittman-Robertson Act, contribution to game restoration and management, 681.

Pituitary gonadotropin, chick response to, 189.

Placenta, retained, effects of stilbestrol, 392.

## Plague—

common brown rat as reservoir, 75.

distribution by mammals in United States, 350.

swine—see Swine plague.

## Plants—see also specific kinds.

acid-soil factors injuring, determination, 58.

amide synthesis, 491.

and bacterial galls, comparisons of casual agents, 59.

and customs of South Seas, illustrated in Hawaii National Park, 315.

boron—

compounds in, solubility, 184.

requirements and interrelationships, 29.

requirements, relation to photoperiod, 796.

breeder, fifty years' work, 648.

bulbous, flower-development terminology in, 38.

carotene determination in, 154.

cells, diseased, effect of heteroauxine, 207.

chemical analyses and their use, 643.

chemical injections against insects and fungi, 527.

chlorophyll determination in, 154.

chlorosis (lime-induced), Idaho 58.

choice for testing soil deficiencies, factor of photoperiodic response, 795.

cobalt in, determination with nitrosocresol, 151.

copper in, determination by ashing procedures, 152.

copper ions, translocation, 643.

cultivated—

chromosome atlas, 648.

diseases and pests and their control, 219.

minor elements and deficiency diseases, 207.

dioecious, effects of animal sex hormones, 485.

disease(s)—

and pests in Denmark, 1942-43, 670.

and their control, papers, 820.

control, research progress reports, U.S.D.A. 142.

greenhouse control by soil disinfection, 61.

growth substances in, 59.

host-parasite check list revision, distribution of separates, U.S.D.A. 58.

host-parasite check list revision (Leguminosae), U.S.D.A. 57, 58.

introduction prevention, 58.

new records for Arkansas, Louisiana, and Oklahoma, U.S.D.A. 58.

physiological specialization in fungi of, 60.

relation to aerobiology, 508.

report, Dade County, Fla., 1945-46, 336.

research by experiment stations, progress reports (1945), U.S.D.A. 142.

research progress report, U.S.D.A. 141, 142, Ala. 143.

spread by air-borne and insect-borne inoculum, 508.

surveys, psychological aspects U.S.D.A. 58.

## Plants—Continued

- endodermis and collenchyma differentiation by oxidation and adsorption reaction, 797.
- flora of Alaska and adjacent Canada, 33.
- flowering, correlation with nitrogenous food and photoperiod, 185.
- foods, fluorine content, effects, 273.
- foods in fertilizers, prewar world production and consumption, 482.
- forage—*see* Forage plants.
- geographical role, 181.
- growing in sand cultures for experimental work, 781.
- grown on acid soils, comparative effects of lime and gypsum, 787.
- growth—
  - conditions on eroded soils, vegetative cover in relation to, 26.
  - experiments, environmental factors and their control, 781.
  - hormone, content, and geotopic reaction in leaves, 319.
  - physiology, with special reference to concept of net assimilation rate, 318.
- growth regulators—
  - activity, assay by gravimetric method, 35.
  - effect on apple drop after frost, 51.
- effect on forest tree seedlings, 55, 56.
  - in diseased plants, 59.
  - in Meredith's actinomycete, 60.
  - in sewage products, 182.
  - new carriers, 319.
  - role in court-noué of grape, 78.
  - rooting of cuttings treated with, 49.
- growth with nutrient solutions, I-III, 487.
- hillculture—*see* Hillculture.
- historical geography, 181.
- hormones, reduction of bud, blossom, and pod drop of canning string beans, 675.
- immigrants and stowaways, romantic story, book, 637.
- manganese deficiency, detection by tissue tests using tetramethyldiaminodiphenylmethane, 509.
- mitosis-respiration correlation in, 37.
- molybdenum in, microdetermination, 152.
- nitrate occurrence and assimilation, 183.
- nutrition—
  - and hydrogen ion, 183.
  - influence of coarsely vs. finely ground limestone, 183.
  - relation to disease development, III, fusarium wilt of tomato, 515.
  - study by grafting method, 36.
  - study by sand-culture techniques, 58.
- of Indiana, distribution records, 34.
- organic food materials, translocation, relation to movement of 2, 4-dichlorophenoxyacetic acid, 320.
- pathologists, recruitment and training in Great Britain, report, 669.
- physiology in the U.S.S.R. 639.
- potash in soils vs., 175.

## Plants—Continued

- protection from black beetle by DDT, 531.
- quarantines, 58.
  - affecting interstate shipments, State and Territorial, U.S.D.A. 201.
- research, soilless culture, large-scale, 783.
- respiration, monographic review, 37.
- rubber—
  - in tissues, stain technique, 21.
  - synthesis in, mechanism, 184.
- rubber-producing, estimation of rubber content of live roots, 184.
- samples, mineral contamination from grinding, 150.
- solutions in, streaming movements, 642.
- starch determination in, polarimetric method, 153.
- storage organs, respiration, relation of anaerobic to aerobic, 492.
- succession in grassland, quantitative study, 182.
- temperatures, internal, measurement by thermocouples, 486.
- tissue, effect of colchicine and acenaphthene with X-rays, 207.
- tissue, non-woody, holocellulosic component, separation, Mass. 302.
- tissues, prolonged culture in absence of growth factors, 488.
- top-root ratios, effect of top environment and flowering, 795.
- toxicity, 715.
- trace elements in, book, 29.
- variety comparisons, agrobiologic test for normality in, 173.
- vascular—
  - of Maryland, catalog, 180.
  - of Ohio, catalog of additions, 180.
- virus diseases and insect vectors, Hawaii 820.
- xanthophyll determination in, 154.
- Plant Disease Reporter—
  - 1946, U.S.D.A. 335, 819.
- index to Supplements 152-159, 1945, U.S.D.A. 670.
- index to Volume XXVIII, 1944, U.S.D.A. 819.
- Plant Industry, Soils, and Agricultural Engineering, Bureau of, report of Chief (1945), U.S.D.A. 141, 142.
- Plantain scab, *Sphaceloma plantaginis* n. sp. causing, 679.
- Plasma—*see* Blood plasma.
- Plasmodium—
  - circumflexum* in ruffed grouse in Ontario, 387.
  - elongatum* in Pekin ducks, 387.
- gallinaceum—
  - Aedes lepidus* as vector, 87.
  - exoerythrocytic forms, growth in tissue culture, 249.
  - immunological relationships, 250.
  - in vitro opsonic tests, 250.
  - in young chicks, IV-VI, 387.
  - increased parasitemia, 249.

- Plasmodium*—Continued  
*gallinaceum*—Continued  
 nonpigmented forms, infection of chick embryos, 250.  
 streptomycin effects, 107.
- lophurae*—  
 immunological relationships, 250.  
 in vitro opsonic tests, 250.  
 increased parasitemia following X-irradiation, 249.  
 infection in ducks, chemotherapy, continuous intravenous, 251.
- relictum* in canaries and pigeons, cryptozoites and metacryptozoites, 387.
- Plaster of paris blocks, moisture tension, relation to heat transfer and electrical resistance, 785.
- Plastics, protein, saturation water content, determination, 472.
- Plastid variegations, 646.
- Platypus compositus*, citrus attacked by, 77.
- Plecoptera of Indiana, list, 80.
- Pleistocene deposits, selenium occurrence in South Dakota, 789.
- Pleocoma* spp., preliminary key, 831.
- Plow, use for application of fertilizer, Minn. 312.
- Plum culture in Missouri, Mo. 202.
- Plum curculio control, 225.
- Plumbing, handbook, 108.
- Plusta gamma* larvae, transmission of tobacco mosaic virus, 341.
- Plutella maculipennis*—see Diamondback moth.
- Pneumoencephalitis, avian, status in U.S., 720.
- Pneumonia, ovine, contagious, caused by filterable virus, 394.
- Polkilocytosis in dairy cattle, effect of yeast and pyridoxine, 382.
- Point Reyes Dairymen's Association, reorganization, proposals, Calif. 408.
- Poison—see also specific kinds.
- Poisonous plants—see Livestock poisoning; Plants, poisonous; specific animals and plants.
- Polarimetry, maltose assay by, 16.
- Pole rot in Connecticut, Conn. [New Haven] 670.
- Poles, shade tent, preservation, Conn. [New Haven] 669.
- Polilla, West Indian dry-wood termite, 837.
- Pollen—  
 distance dispersion rates, 208.  
 germination, mutual stimulation, 37.  
 ragweed, elimination by 2,4-D with care around corn plants, [N.Y.] State and Cornell 814.  
 shed, Monterey pine, 208.  
 substitute, supplying to bees by dryfeeder, Ohio, 370.  
 tube—  
 course, in cultivated barley, 805.  
 establishment in diploid and tetraploid maize, comparative rates, 798.
- Pollination of tree fruits and nuts, Wash. 202.
- Pollinators, insect, of alfalfa in California, 535.
- Polymeric fat acids, polyamides, 463.
- Polyphosphates, aid in home jelly making, 883.
- Polyploidy in plants, review of colchicine research on, 185.
- Polypores, resupinate, from Great Lakes region, Mich. 209.
- Polysaccharides—  
 bacterial, effect on soil aggregation, 171.  
 pyranose rings, configuration, 293.
- Polysulphides, polymeric organic, fungicides and spray adjuvants, 510.  
 synthesis from sucrose by *Streptococcus* s. b. e. strains, 790.
- Polytechnic Institute Arborctum, ecological survey, U.S.D.A. 206.
- Pond, farm, management in Michigan, preliminary report, Mich. 683.
- Popcorn, hybrid, in Indiana, Ind. 659.
- Popillia japonica*—see Japanese beetle.
- Population—  
 farm, prospects of Minnesota, Minn. 536.  
 growth and food demand, U.S.D.A. 119.  
 reproduction in Louisiana, La. 874.  
 white, of Louisiana, educational status, rural-urban differences, 875.
- Poria, new species, descriptions, 347.
- Pork—  
 canning methods, effect on riboflavin content, Ky. 894.  
 cause of pregnancy disorder in rats, Iowa 887.  
 cooking methods, effect on riboflavin content, Ky. 894.  
 cooking retention of thiamine, riboflavin, and niacin, 428.  
 production, relation to feed consumption, U.S.D.A. 725.  
 trichinae killed by 120 degrees F., 395.  
 vitamin content in relation to thiamine in rations fed, 93.  
 vitamin potency, influence of rations, Mo. 422.
- Posts, fence—see Fence posts.
- Potash—  
 in fertilizers, determination, factors influencing, 151.  
 in plants vs. soils, 175.  
 requirements of cotton rotated with peanuts, 807.
- Potassium—  
 chemical relationship to magnesium in organic and sandy soils of Florida, 787.  
 colorimetric determination, 300.  
 content of—  
 leaf tissue, determination by micro-methods, 301.  
 silicates, determination, 299.  
 deficiency in dog, 395.  
 dichromate, color of aqueous solutions, spectrophotometric study, 150.

- Potassium—Continued  
 effects on nitrogenous constituents of *Ananas comosus*, 507.  
 iodide supplementation, effect on excretion of iodine by normal human subjects, 741.  
 plant-nutrient value of sodium vs., 28.  
 salicylate, effect on tobacco mosaic virus, 213.  
 soil needs in New Jersey, N.J. 174.  
 specificity for growth of *Aspergillus niger* 644.
- Potassium-low rations for rats, response to boron supplements, 273.
- Potato(es)—*see also* Sweetpotato(es).  
 aphid control by DDT in—  
   New York, 690.  
   northeastern Maine, 690.  
 ascorbic acid content—  
   factors affecting, Nebr. 897.  
   influence of variety, environment, maturity, and storage, 897.  
 bacterial soft rot—  
   of early, solar heat relations, 24.  
   temperature effects, 24.  
 blight, control by copper fungicides, 672.  
 blooming, spray-material effects, 66.  
 bolters, explanation based on photoperiodism, 339.  
 breeding for disease resistance, 66.  
 breeding method, Minn. 186.  
 commercial strains, susceptibility to stem-end browning, 690.  
 cooked, ensilage, effect of temperature and length of storage, 840.  
 cutting knife for saving labor, reducing spread of ring-rot, and reducing equipment costs, Colo. 862.  
 dehydrated—  
   for fattening steers, Colo. 704.  
   peroxidase test for blanching adequacy, 122.  
 demonstration plots, spray and dust treatments, 1945, N.Dak. 211.  
 early blight fungus, spray and dust materials for, evaluation, N.Dak. 211.  
 fertilizers, 660.  
 fields, Swedish, insect fauna, and role as vectors of virus diseases, 211.  
 first European, origin and reaction to length of day, 503.  
 general treatise, 47.  
 golden nematode on Long Island, N.Y. State and Cornell 825.  
   life history, 69.  
 green dwarf, virus disease, 824.  
 growing and marketing, income and expenses, Cumberland Plateau, 1943-44, 869.  
 insect pests, spray and dust materials, evaluation, N.Dak. 211.  
 judges' scoring of boiled, discriminant functions in comparing, 121.  
 late blight—  
   1946, U.S.D.A. 824.  
   bordeaux trials against, 68.
- Potato(es)—Continued  
 late blight—Continued  
   copper fungicides in field trials against, 68.  
   epidemiology, study aids, Minn. 212.  
   losses due to disease in North Carolina, 1943-45, N.C. 513.  
   Maine-grown, vitamin C content, effects of storage, 661.  
   marketing, wholesale, in Knoxville, Tenn., Tenn. 729.  
   nitrogen content, nature and distribution, 645.  
   pink rot, host-parasite relations, 513.  
   price changes, causes, Pa. 729.  
   production, costs, materials, and practices on Cumberland Plateau, Tenn. 112.  
   production on muck soils, Ind. 198.  
   retailing and consumption in Knoxville, Tenn., Tenn. 729.  
   ring rot, in California, laboratory and field data, 513.  
   ring-rot-like symptoms by soft-rot bacteria in, 68.  
   root crop diseases, 334.  
   rot nematode, *Ditylenchus destructor*, 1945, in Prince Edward Island, 212.  
   sacked, mechanical field loading, N.Dak. 722.  
 scab—  
   control by chlornitrobenzene, 676.  
   control by seed and soil treatment, 514.  
   presence, residual effect of crop rotations, Mich. 661.  
 seed—  
   certified, value, N.Dak. 328.  
   fusarium dry rot as influenced by bruising and disinfecting, 67.  
   pieces, sclerotium rot, 68.  
 seedling varieties, resistance to natural spread of leaf roll, 825.  
 soft rot in 1945 crops, 672.  
 solanine content, estimation and physiological role, U.S.D.A. 645.  
 spraying and dusting tests (1945), 67.  
 starch, physical properties due to different culinary quality, 412.  
 stored, *Fusarium* spp. in wastage of, 67.  
 tubers, internal necrosis, type caused by psyllids, 513.  
 tubers, pathogenicity of *Bacillus polymyxa* in Alberta, 339.  
 tubeworm—  
   bacterial infection of larvae, 77.  
   pupae, separation of *Macrocentrus ancyliovorus* cocoons from, factors, 535.  
 varieties—  
   American, descriptions and key, U.S.D.A. 503.  
   grown in North Dakota, 1945, N.Dak. 328.  
 virus diseases, determination by serological methods, 211.  
 virus reactions of varieties compared, 66.  
 virus Y, susceptibility, varietal differences, 672.

- Potato(es)—Continued  
 vitamin C content, influence of storage conditions in Maine, 897.  
 vitamin C content, plant and tubers, and factors influencing, 136.  
 wart disease, immunity trials of new varieties, 68.  
 yields—  
   and tissue composition, effect of soil characteristics and fertilization, 810.  
   residual effect of crop rotations, 661.  
   spacing and seed-size relations, Maine 198.  
*Potentilla norvegica*, Duvel buried seed experiment, final results, U.S.D.A. 201.  
 Potentiometer, usefulness for plant breeders, 640.  
 Poultry—*see also specific kinds*.  
   breeding diets, supplements for distillers' byproducts in, 94.  
   disease(s)—  
     common to farm flocks, 248.  
     diagnosis and control, chart, 107.  
     prevention and control, 396.  
     research progress reports, U.S.D.A. 99.  
   dressed, evisceration, quality from defrosted, dressed stock, 411.  
   farms, organization and management in Massachusetts, Mass. 404.  
   fattening potency of estrogen feeding, rapid assay method, 46.  
   feeding, practical, Ill. 846.  
   feeding vitamins, Nebr. 846.  
   feeds and rations, composition and productive energy, Tex. 706.  
   feeds, riboflavin, photolysis, 707.  
   growth in progeny, rate to ten weeks, relation to shank length of parents, 498.  
   houses, electric ventilation, 258.  
   inbred hybrid, experiments, 653.  
   lighting for egg production, Wash. 705.  
   marketing practices, West Virginia, W.Va. 263.  
   production, treatise, 234.  
   products, *Salmonella* in, 398.  
   rations—  
     B complex vitamins in rumen, Colo. 235.  
     high wheat, riboflavin and manganese supplements, 708.  
     soybean oil meal, W.Va. 235.  
   research progress reports, U.S.D.A. 90, 140, 141, Ala. 143.  
   Rhode Island Red, annual molt, Mass. 380.  
   salmonellosis in Great Britain, 721.  
   Single-Comb White Leghorn, irises—  
     depigmented, histopathological study, 326.  
     pigment-free, blood vessels and "ground color," 548.  
   Wyandotte, fertility and hatchability, influence of heredity and environment, 498.  
   farm—  
     horse, factors affecting, Mich. 378.  
     history and forecast, 254.  
 Prairie climate, trees, 167.
- Precipitation—  
 effectiveness, new formula, 310.  
 in northern Rocky Mountains and North Pacific States region, foreshadowing, 310.  
 in Tennessee River Basin, annual 1945, 630.  
 local 8-hour forecasting, single-radiosonde analysis, 474.  
 seasonal range, 310.  
 winter, foreshadowing in Florida and Montana, 23.  
 Precipitin production in chickens, II, in vitro, rise of interfacial titers and precipitin formation, 566.  
 Precipitin reactions, flocculation rate, theory, 100.  
 Pregnancy disorder induced by pork, modifications in blood, urine, and tissues of rats, Iowa 887.  
 Pregnant-mare serum, chick response to, 189.  
 Pressure cookers—  
   food spoilage and defective gauges, 125.  
   gauge testers, making and using, 139.  
 Prices—*see also specific commodity*.  
   agricultural—  
     and national income, 724.  
     index numbers (1915), Ohio 110.  
     plans, quantitative comparison, 724.  
     postwar, U.S.D.A. 110.  
   control, farmers' stake in, W.Va. 118.  
   control, international, through buffer stocks, 724.  
   farm, policy, views, 724.  
   farm land—*see* Land(s).  
   paid by farmers during two wars, U.S.D.A. 409.  
   parity policies and national employment, aspects, 724.  
   policy for promotion of income from farming, 581.  
 Prickly pear, biological control, 225.  
 Prickly pear, fusarium disease, 829.  
 Produce, prepackaged, preference of housewives, Ohio 872.  
 Producer gas combustion, thermodynamics of, 162.  
 Propionates, inhibition of mold growth, active agent responsible, 612.  
 Protamine zinc insulin, antibacterial activity, 313.  
 Protein(s)—  
   added to protein-free diets compounded with amino acids, growth-stimulating action, 591.  
   amino acid composition, assay, 128.  
   animal, amino acids in, microbiological determination, 618.  
   blood plasma, changes produced by heat in presence of sugars, electrophoretic analysis, 765.  
   bristles from, 163.  
   concentrates, pepsin digestible fraction, sulfur content, 610.  
   cottonseed, color improvement, 764.  
   denaturation, studies, 292.

## Protein(s)—Continued

- diet, low, amino acid administration followed by hemoglobin formation, 593.  
 dietary, effect on liver fat, 737.  
 dietary level, effect on vitamin A utilization by rats, 133.  
 from muscle meat of cow, buffalo, and goat, biological value, 275.  
 growth-promoting powers, correlations with streptogenin content, 449.  
 hydrates, peanut—  
   preparation and properties, 163.  
   use as tacky and remoistening adhesives, 164.  
 hydrolysates—  
   histidine in, determination, 618.  
   lysine in, microbiological assay, 15.  
 ingested, sensitizing influence, nonspecific reactions, relationship in pullorum disease, 568.  
 leucine content, 1.  
 methionine determination, 773.  
 peanut, color improvement, 764.  
 peanut, electrophoretic investigation, I, II, 763.  
 plastics, saluration water content, determination, 472.  
 requirements of adult human beings in content of individual foods and food combinations, 592.  
 supplement in chick rations, shark meal, 707.  
 yeast, nutritional value to rat and chick, 591.  
 Protein-auxin complexes of wheat grain, 485.  
 Protein-formaldehyde reaction, methylene bridges and unreactivity of benzoyl-d(—)-allanine, 764.  
 Protoanemonin, antibiotic from *Anemone pulsatilla*, 180.  
 Protoplasm—  
   *Blodva*, structural viscosity, effects of various agents, 323.  
   spiral form and movement in, mechanism, 37.  
   torsion in myxomycete, 37.  
 Protozoa, growth in tissue culture, I, *Plasmodium gallinaceum*, exerythrocytic forms, 249.  
 Protozoa, tick-transmitted, in peripheral blood of clinically healthy cattle in Palestine, 392.  
 Protozoology, book on, 77.  
 Provitamin A activity and stereochemical configuration, IV, neo- $\alpha$ -carotene B and neo- $\beta$ -carotene B, 615.  
 Provitamins, colorimetric reaction, 18.  
 Prunes—  
   French, irrigation effects on growth-yield-drying ratios, 52.  
   Italian, ripening in relation to maturity and storage, 53.  
   microbiology during handling and drying, 417.

## Pruning—

- forest trees by finger-budding method, 668.  
 trees by annual removal of lateral buds, 668.  
 wounds in apple trees, treatment and healing, [N.X.] Cornell 331.  
*Pseudococcus comstocki*—See Comstock mealybug.  
*Pseudomonas pyocyanea*, metabolites obtained in culture, preparation methods and properties, 242.  
 Pseudopyridoxine—  
   activity, basis of, 158.  
   excretion in urine and sweat of normal individuals, 276.  
 Psyllids, cause of internal necrosis of potato tubers, 513.  
 Pteridophytes, of Maryland, catalog, 180.  
*Pteris aquilina*—See Bracken.  
 Public health nutrition appraisal, 127.  
 Publications of agricultural experiment stations, statistics (1945), U.S.D.A. 143.  
*Puccinia*—  
   *graminis*, biometrical study of spores on various hosts, 63.  
   *graminis tritici*, physiologic races—  
   Canada, 1919–44, 342.  
   France, 512.  
   spp., reactions of interspecific oats cross to, 41.  
 Puerto Rico—  
   coffee soil, saving, U.S.D.A. 666.  
   fleas, 229.  
   literature, bibliography, 1493–1930, P.R.U. 757.  
   sweet corn, successful variety, U.S.D.A. 505.  
   tobacco farms, credit, 1939–40, P. R. U. 727.  
 Puerto Rico Station, report—  
   1944, P.R. Fed. 441.  
   1945, P.R. Fed. 605.  
 Pullets—  
   high protein diet, relation to nonspecific agglutinins for *Salmonella pullorum*, 568.  
   production and mortality of White Leghorn, Rhode Island Red, and Barred Plymouth Rock, N.J. 378.  
   sexual maturity and early egg weight, effect of selection for shank length, 498.  
   summer shelter on range, U.S.D.A. 257.  
 Pullorum disease—see also *Salmonella pullorum*.  
   bacterial syndrome in epidemic, 106.  
   control, 106.  
   diet effects on epidemic, 106.  
   of pouls, sulfamerazine as prophylactic, 398.  
   rapid whole-blood test, use, U.S.D.A. 860.  
   studies, VIII, sensitizing influence of ingested proteins, 568.  
   treatment by rapid antigens, 721.  
   treatment by sulfamerazine, 568.  
   whole-blood test for, antigen preparation for, 106.

- Pulpy kidney disease—see Enterotoxemia.
- Pump—  
 installation, salt marsh drainage by, 86.  
 magnetic glass surfaced, for circulating liquids in high-vacuum system, 298.  
 mobile-dredge, for mosquito control, 86.
- Purdue University, notes, 288.
- Pycnometer, for volatile mixtures and low-temperature determinations, 147.
- Pyelonephritis, bovine infectious, diphtheroids associated, 103.
- Pyometra following retained fetal membranes, effects of stilbestrol, 392.
- Pyracin, agency in production of folic acid, 616.
- Pyrausta nubilalis*—see European corn borer.
- Pyrethrum—  
 aerosols, efficacy against common malaria mosquito and housefly, 541.  
 control of adult mosquitoes, outdoors, applied with ground equipment, 368.  
 extract, evaluation, chemical and biological methods, 222.  
 spraying for malaria control in India, 698.  
 toxicity to houseflies, comparison with DDT compounds, 229.
- Pyridoxal—  
 assay system for, 179.  
 content in natural products, 158.  
 phosphate—see also Codecarboxylase.  
 phosphate in transamination, 768.  
 stability, 158.  
 vitamin activity for micro-organisms, 157.
- Pyridoxamine—  
 content in natural products, 158.  
 stability, 158.  
 vitamin activity for micro-organisms, 157.
- 4-Pyridoxic acid, in urine—  
 and sweat of normal individuals, 276.  
 isolation, structure, and synthesis, 148.
- Pyridoxine—  
 chick requirement, high, 94.  
 deficiency—  
 effects of casein vs. tryptophan on health and xanthurenic acid excretion in mice with, 128.  
 in dogs, fate of tryptophan in, 601.  
 in rats, blood regeneration, 284.  
 of pantothenic acid vs. effect on nervous tissues of swine, 104.  
 derivatives, function, 179.  
 excretion in urine and sweat of normal individuals, 276.  
 function, conversion of members of vitamin B<sub>6</sub> group into codecarboxylase, 769.  
 function in lactic acid bacteria, 179.  
 4-pyridoxic acid from oxidative metabolism of, 148.  
 stability, 158.  
 therapeutic effect on poikilocytosis in dairy cattle, 382.
- Quail—  
 bobwhite—  
 food, winter, in Virginia, 524.  
 grit, mechanical value, 525.
- Quail—Continued  
 bobwhite—Continued  
 mobility in southwestern Texas, 524.  
 reproduction in southwestern Texas, 524.  
 history and general study in Wisconsin, 76.  
 in Wisconsin, 682.  
 infection by *Salmonella bacilly*, 861.  
 parasite studies in Mississippi, 388.  
 valley, management in California, Calif. 76.
- Qualla* sp., galleries of wood boring insect, white deposit, composition and origin, 544.
- Quarantine(s)—  
 emergencies, present-day address, 670.  
 insect, progress in, U.S.D.A. 141.  
 plant—see Plant(s) quarantines.
- Quick decline—  
 orange trees, 217.  
 studies, progress report, 346.  
 rootstock, factor, 346.  
 studies, 346, 347.
- Quince, catalase of leaves, variations in lime chlorosis, 73.
- Quinidine, metabolism in birds and mammals, 241.
- Quinine—  
 degradation in duck, chicken, and dog, 242.  
 metabolism in birds and mammals, 241.
- Rabbit(s)—  
 cottontail—  
 bone growth as age criterion, 521.  
 winter food habits, 350.  
 laboratory, scab mite control by DDT, 369.  
 tick, as ectoparasite of man, 88.
- Rabies—  
 control, 396.  
 diagnosis, rapid method, 396.  
 immunity, antibody content of serum in relation to, 105.  
 outbreak in dairy herd, 715.
- Raccoon, new host for *Microphallus* sp., 682.
- Radiation and living cells, 648.
- Radiations, biological action, 606.
- Radio—  
 handbook for extension workers, U.S.D.A. 121.  
 service, attitude-survey of farm and small-town-people, U.S.D.A. 120.
- Radioactive—  
 elements, effect on root-nodule bacteria, 638.  
 elements, root absorption, 36.  
 isotope, iron absorption in anemia determined by, 130.
- Ragweed—  
 effects of 2,4-D, Mich. 664.  
 pollen, elimination by 2,4-D with care around crop plants, [N.Y.] Cornell 814.
- Rain, evolution, 630.
- Raindrops, size, measurement, 309.
- Rainfall—  
 annual, geographic variation on Oahu, 310.

## Rainfall—Continued

- artificial, production devices for tests of water-repellent and waterproof materials, 750.
  - distribution in hurricane analyzed, 23.
  - Hale double solar-cycle variation in western Canada, 628.
- Ramie, fiber yield, effect of plant spacing and harvesting time, 811.
- Ramie, types, comparative evaluation under Cuban conditions, 811.
- Rams, fertility, lowered, environmental temperature and thyroid gland involvement, Mo. 800.
- Ramulispora sorghi*, sooty stripe of *Sorghum* spp. due to, 69.
- Range—
- grasses—see Grass(es), range.
  - grassland, succession in conservatively grazed, 191.
  - land of America and management research, Utah 373.
  - mountain, soil erosion, effects of pocket gopher, 349.
  - seeding with rye nurse crops, 327.
- Rape seed, goitrogenic effects in chicks, 46.
- Raspberries, yellow rust, physiologic races in western Washington, 346.
- Rat(s)—
- albino—
    - complete life cycle, influence of calcium intake level, 739.
    - food consumption, seasonal changes and growth rate, 275.
    - growth rate and seasonal changes in food consumption, 275.  - bacterial infections, relation between diet and defense mechanisms, 559.
  - common brown, as plague reservoir, 75.
  - feeding succinylsulfa-thiazole, 276.
  - flea of Puerto Rico, 229.
  - food digestibility, measurement of digestibility of human foods and animal feeds, 275.
  - growth and lipotropism, I, dietary requirements of methionine, cystine, and choline, 738.
  - livers, storage of vitamin A, measure of relative values of carotenes in foods, 278.
  - mammary gland, as influenced by thiouracil, 46.
  - Norway, common, poisoning by ANTU, instructions, 350.
  - Norway, study techniques, 220.
  - nutritional value of yeast protein, 591.
  - pyridoxine-deficient, blood regeneration, 284.
  - response to boron supplements on rations low in potassium, 273.
  - ship infestations increasing, 75.
  - wild Norway, assays of rodenticides, comparative, 350.
- Rations low in potassium, boron supplements, response of rats, 273.
- Rattus norvegicus*—
- plague reservoir, 75.
  - study techniques, 220.
- Rayon, dyed cellulose acetate, atmospheric fumes, fastness evaluation, 605.
- Rayon fabrics used for glass curtains, Ohio, 750.
- Reaction vessel for maintenance of constant pH by continuous electrometric titration, 769.
- Real estate, farm—
- activity in Oklahoma (1941-44), Okla. 117.
  - inheritance, U.S.D.A. 407.
  - situation trends, Ohio 110.
- Red color test for rotenone, applications, 14.
- Red spider mite, control on roses, N.Y. State and Cornell 856.
- Redwings, grain taken in cornfields, relation to number of ears opened, U.S.D.A. 525.
- Reflectometer, low-cost, and method for comparing detergency, 605.
- Reforestation in Indiana, trees for, Ind. 205.
- "Reforestator," tree-planting machine, description, Mich. 109.
- Refrigeration—
- household, manual No. 1, 724.
  - mechanical, application to ranch egg cooling, 258.
- Regional Pasture Research Laboratory, activities and general information, U.S.D.A. 192.
- Regional Poultry Research Laboratory, East Lansing, Mich., report, 1945-46, U.S.D.A. 859.
- Reindeer, grazing on Alaska tundra, 349.
- Repellent(s)—
- bee, 89.
  - insect, 2-ethylhexanediol-1,3, 79.
  - mosquito, new, investigation, 228.
- Research workers, in agricultural experiment stations, statistics (1945), U.S.D.A. 143.
- Research and Farming, 1946, N.C. 606.
- Resins, softening points, ring and ball, constant-temperature determination, air-bath method, 303.
- Respiration, mitosis correlation in plants, 37.
- Rhinitis, infectious, in swine, 247.
- Rhipicephalus*—
- appendiculatus*, survival of Nairobi sheep disease virus in, 230.
  - neavei*, 1912, vector of East Coast fever, 230.
- Rhizobium*—
- leguminosarum*, ecology and physiology of strains compared, 34.
  - spp., antibiosis absent among, 180.
- Rhizoctonia root canker development of alfalfa, effect of soil temperature, U.S.D.A. 822.
- Rhipocerta dominica*, oviposition, influence of temperature, humidity, and density, 226.
- Rhizophydium* spp., Brazilian chytrids, 637.
- Rhodanese, activity measurement, 767.

*Rhus* spp.—

Chinese gallnuts on, 57.  
tanning sheepskin skivers by, comparisons, 164.

*Rhyacionia frustrana*—see Nantucket pine moth.

## Riboflavin—

analogs, effect on utilization of riboflavin and flavin adenine dinucleotide by *Lactobacillus casei*, 179.

and thiamine in cereal products, combined determination, rapid method, 470.

assay, in low-potency foods and feeds, 160.  
content of—

dried legume seeds, 428.

eggs, assay by fluorometric method, 160.  
grain and flour of Kansas-grown wheat varieties, 280.

pork, effect of cooking methods, Ky. 894.  
pork, relation to thiamine fed, 93.

summer squashes, 277.

tea, 280.

tropical foods, 745.

determination, methods, comparison, Mass. 303.

effects on production of corneal vascularity and healing of corneal lesions, 600.  
estimation, rapid field method, 624.

fecal, of rats receiving varying intakes of riboflavin, 430.

ice cream as source, 131.

in poultry feeds, photolysis, 707.

intake, effect on content of egg whites and yolks from individual hens, 708.

level, significance in ration of breeding hens, 548.

requirements of monkey, and new factor found in liver, 599.

retention in cooking pork and processing bacon, 428.

retention in preparation of overseas hams and bacons, 279.

supplement for high wheat poultry rations, 708.

synthesis by *Clostridium*, influence of iron inactivation by 2,2'-bipyridine, 31.

synthesis by *Neurospora*, genetic differences in strains, 35.

utilization by *Lactobacillus casei*, as influenced by riboflavin analogs, 179.

## Rice—

bran extract, antioxygenic synergism in preservation of carotene, 743.

fields, airplane spraying with DDT against mosquito larvae, 87.

polish, microbiological biotin assays, growth stimulants, 429.

production, economic factors in, Tex. 112.

vitamin content, effect of milling, processing, washing, cooking, and storage, Ark. 893.

weevil small strain, oviposition, influences, 226.

white, nutritional improvement, 893.

Rickets experimental, in hamster, 748.

Rinderpest immunization of cattle, 715.

Rinderpest, St. Lawrence River project, papers I—XVI, 562.

Ring rot of potatoes in California, laboratory and field data, 513.

Rivers, and rocks, book, 143.

Roach powder, DDT formula, improvement by "Lethane A-70," 697.

Roaches, arsenite-injected, concentration-survival time curves, analysis, 539.

*Robinia pseudoacacia*, Duvel buried seed experiments, final results, U.S.D.A. 201.

Rocky Mountain spotted fever vector, American dog tick, control, preliminary tests, 701.

Rocky Mountain National Park, Colo., big-horn sheep, ecology, 219.

## Rodent(s)—

activity in mixed prairie near Hays, Kans., 220.

bird lice of, descriptions, 88.

control, 352.

distribution of plague in United States, 350.

grey lung virus, 683.

Rodenticide(s)—see also ANTU.

Rodenticides, assays on wild Norway rats, comparative, 350.

## Root(s)—

formation, in cuttings, leaf role in, 35.

Inorganic ions, absorption, transport, and exudation, 489.

moisture-stress in container of saline soil, evaluation techniques, 171.

## nodule bacteria—

assimilation of molecular nitrogen of atmosphere, effect of radioactive elements, 638.

development, effect of radioactive elements, 638.

in Zygomycellaceae, 639.

isolation from clover species, host specificity, 316.

radioactive rubidium and phosphorus absorption in barley, 36.

rots of grains and grasses in northern Great Plains and Western States, U.S.D.A. 821.

tip smears, preparation, use of enzymes, 793.

Root-knot nematode, *Heterodera marioni*, host-parasite relationships, II, effects of host on parasite, 348.

Rooting, of cuttings treated with growth substances, 49.

## Rose(s)—

garden, growing, Iowa 205.

hips, vitamin C and carotene content, 424.

multiflora, use as farm hedge, 817.

red spider mite control by azobenzene, N.Y. State and Cornell 356.

unions, bud and graft, failure due to *Chalaropsis thielavioides*, 218.

Rotation, crop, residual effect on potato yield and presence of scab, Mich. 661.

- Rotenone—  
   color tests for, nonspecificity, 156.  
   content of *Derris elliptica*, effects of altitude and water supply, 794.  
   dusts, toxicity, effect of mineral composition and particle size in dispersants, 832.  
   from yam bean resin, 9.  
   modified red-color test for related compounds and, applications, 14.  
 Rotenone-bearing devil's-shoestrings, response to fertilizer applications, 807.  
 Rotifers, parasites, Brazilian chytrids, 637.  
 Rotproofing fabrics—  
   dimethylglyoxime-copper treatment, 900.  
   soil burial test, 900.  
 Roughage digestibility, crude fiber effects in cattle vs. zebu, 91.  
 Roundworms—*see specific names*.  
 Rubber—  
   content of—  
     crude rubber products, determination, rapid photometric method, U.S.D.A. 777.  
     guayule, effects of variations in soil moisture stresses, 807.  
     guayule tissue, determination by rapid photometric method, U.S.D.A. 777.  
   cooperative research in Costa Rica, U.S.D.A. 204.  
   crude, products, rubber content, rapid photometric methods, U.S.D.A. 777.  
   estimation of content in live roots of plants, 184.  
   from *Cryptostegia* leaf latex, 162.  
   hydrocarbons in plant materials, differentiation, 777.  
   in plants, synthesis mechanism, 184.  
   non-latex, content of *Cryptostegia*, 796.  
   production from thickly seeded guayule, 808.  
   staining in ground or milled plant tissues, 21.  
 Rubidium, radioactive, absorption by barley roots, 36.  
*Rudbeckia hirta*, Duvel buried seed experiments, final results, U.S.D.A. 201.  
*Rufinus*, herbal of, printing of Thirteenth century manuscript, 30.  
 Rum, technology of manufacture, P.R.U. 22.  
 Rumen contents, source of B complex vitamins for poultry rations, Colo. 235.  
 Ruminant(s)—  
   blood constituents, changes in diseases, 560.  
   physiology of digestion, 372.  
   utilization of thyroxine, thyroprotein, and intermediate products, relation to route of administration, Mo. 372.  
 Rumplessness, insulin-induced, of chickens, II, III, 802.  
 Rural—  
   environment, living and working values, [N.Y.] Cornell 119.  
   health conditions, survey, U.S.D.A. 120.  
 Rural—Continued  
   institutions, Kansas, II, pioneer in rural electrification, 875.  
   life—  
     effects of war in Missouri, 1939-45, Mo. 873.  
     in Iowa, 1918-1946, 874.  
     postwar problems and programs in Nebraska, committee reports listed, Nebr. 111.  
     promises for future, N.Y. State and Cornell 874.  
     research by experiment stations, progress reports (1945), U.S.D.A. 142.  
     people, radio service attitudes, survey, U.S.D.A. 120.  
     public services, postwar revenues in Maryland, Md. 733.  
   social—  
     organizations in U.S., Latin America, and Germany, textbook, 409.  
     trends in New York, 587.  
   Rural-urban migration and marriage rate, hypothesis, 409.  
   Rural Health Services Association of Wheeler County, Tex. 875.  
   Rushes, of New Jersey swamp, 180.  
   Russian dandelion—*see* Dandelion, Russian; *Taraxacum kok-saghyz*.  
   Rust fungi, white pine blister rust distinguished from pinyon rust in white pine, U.S.D.A. 58.  
   Rutgers University, notes, 758.  
   Rutin, in *Hydrangea paniculata grandiflora* flowers, isolation, 9.  
   Ryanex, control of oriental fruit moth, comparison with DDT, 694.  
   Rye—  
     ground, utilization by growing chicks, comparison with ground wheat, Nebr. 547.  
     leaf, first, cultivated in isolation or attached to intact plant, growth and structure, 318.  
     nurse crops in range reseeding, 327.  
     varieties, performance tests (1945), N.C. 192.  
     × wheat × *Elymus*, trigeneric hybrids, 649.  
   Ryegrass, phiala blind-seed disease, 69.  
   Sabadilla, control of—  
     green stink bug, 77.  
     hairy chinch bug, 833.  
   Sabethine mosquito, new, from Jamaica, *Phoniomyia hirsuta*, 228.  
   Saccharides, simple—  
     acetates, 4.  
     butyrates, 4.  
     propionates, 4.  
   Saccharification of wood, 21, 22.  
   *Saccharomyces cerevisiae*, mutant, 41.  
   *Saccharum robustum* and other wild relatives of "noble" sugarcanes, 323.  
   Sacks, DDT-impregnated, insect control, 85.  
   Safflower seeds and oils, 611.

- Sainfoin, verticillium wilt, cause and incidence, 673.
- St. Lawrence River Basin, stream flow measurements, 1944, 399.
- Salmonella*—
- abortus-equi*—
    - etiological significance, 719.
    - infection in man, 853.
  - bareilly* in quail, 861.
  - carriers artificially infected, 252.
  - choleraesuis* var. *kunzendorf* septicemia in swine, 858.
  - cultures, "induced" antigen, natural occurrence, 389.
  - cultures, non-motile, flagella and flagellar antigens, 853.
  - epidemic from commercially prepared sandwiches, 243.
  - food poisoning transmitted by hen's egg, localized outbreak, 716.
  - in poultry products, 398.
  - infection—
    - in man conveyed by duck's eggs, 716.
    - incidence, type, and bacteriology, in Army in India, 389.
  - isolation from hen's eggs, 252.
  - pullorum*—see also Pullorum disease.
    - cause of gastroenteritis outbreak, 252.
    - nonspecific agglutinins, relation to high protein diet, 568.
  - suispestifer*, in pigs, Nebr. 858.
  - three new types, descriptions, 853.
  - typhimurium*—
    - canine infection, with notes, 242.
    - control by X-ray irradiation, 497.
    - isolation from feces of turkeys, 569.
  - variant, monophasic strains, observations, 716.
- Salmonellosis—
- avian, survey in Great Britain, 721.
  - outbreak in horses and mules, 217.
  - suis*—see Pig typhus.
- Sand cultures—
- growing plants for experimental work, 781.
  - in plant-nutrition studies, 58.
- Sanderson, Dwight, memorial, 873.
- Sandy clay lands, eroded, reclamation in Texas, Arkansas, and Louisiana, 1931-40, U.S.D.A. 631.

- Silage—  
 alfalfa, for fattening steers, Colo. 704.  
 barley-timothy, comparison with molasses-timothy silage for milking cow, N.J. 236.

## Silage—Continued

corn and alfalfa, relation to cheese quality and carotene and vitamin A content, 241.  
grass, chemistry, U.S.D.A. 545.

ground barley-grass, comparison with molasses-grass silage for milking cow, N.J. 236.

meadow crop, loss of nutrients during storage, 370.

molasses-grass, comparison with ground barley-grass silage for milking cow, N.J. 236.

molasses-timothy, comparison with ground barley-timothy silage for milking cow, N.J. 236.

## potato—

cooked, results in pig-feeding experiment, Colo. 233.

effect of temperature and length of storage, 840.

making and feed value for dairy cows, U.S.D.A. 381.

production and utilization in Mississippi, 371.

## Silicates—

crystalline, base exchange in, 145.

potassium content, determination, 299.

sodium content, determination, 299.

Silt loam, Hagerstown, aggregation, seasonal variability, 784.

*Simulium* spp., larvicidal control by DDT, 88.

Sinusitis, infectious, treatment in turkeys, 398.

Siphons, priming value for portable, 107.

*Siphophyto*, review with key to species and new taxonomy, 687.

Sires, Holstein, 1,260, production influence, [N.Y.] Cornell 711.

Sires, improved, use in station herds, Ohio 799.

## Syrup—

apple, by ion exchange process, 161.

invert, preparation, new methods, 765.

maple—see also Maple.

dark color, factors causing, N.Y. State 307.

storage, N.Y. State 307.

*Sitanion*, *Elymus*, and *Agropyron* hybrids, artificial and natural, 648.

## Skunk—

parasites, helminth, in Texas, 221.

scent glands, ablation, 248.

Slags, calcium-silicate, neutralization value, titration, 13.

Slash disposal on Colville Indian Reservation, 254.

Slashbuncher teeth, development and use by Forest Service, 254.

Sludge, sewage (digested), fertilizer value, 29.

Smoke, ineffectiveness for frost protection to fruit crops, 816.

## Smut—

flag, of wheat in Mexico, 511.

loose, four races, reactions of oat varieties and selections, 511.

## Smut—Continued

loose, response of spring barley varieties to floral inoculation, 671.

of sugarcane varieties, effects during crop year 1944-45, 212.

Snares and deadfalls for capturing wildlife, 829.

Soap solutions, foaming properties, 465.

Social trends, rural, in New York, 587.

Society of American Bacteriologists, proceedings of local branches, 313.

## Sociology, rural—

current research, review, 873.

postwar problems and programs in Nebraska, committee reports listed, Nebr. 111.

research by experiment stations, progress reports (1945), U.S.D.A. 142.

## Sodium—

amalgam reductions, continuous electro-metric titration, reaction vessel for constant pH, 769.

chloride, toxicity to chicks of excessive ingestion, 105.

content of silicates, determination, 299.

fluoacetate ("1080"), use in Murine typhus control in Southwest, 358.

fluoride, efficacy in removal of swine ascarids, 718.

hydroxide, bactericidal activity, influence of changes in concentration, 791.

pectate, X-ray diffraction investigation, 294.

sulfamerazine, use in treatment of cecal coccidiosis, 251.

Soft scale, infestation coincident with yellow scale, role of ants in, 77.

## Soil(s)—

acid, plant-injuring factors in, determination, 58.

acid, plants grown on, comparative effects of lime and gypsum, 787.

aggregation, as influenced by bacterial polysaccharides, 171.

alkali, in Iran, 781.

and crops of Oklahoma, report, 1946, Okla. 753.

and soil management, book, 24.

applications of coal, results in Utah, 789.

arid, moisture effects on dissolved and exchangeable ions, 171.

anger, general purpose, Colo. 722.

California Prairie, pedologic study, 783.

carbonaceous residues, utilization, nitrogen requirement, 480.

characteristics and fertilization, effect on yield and tissue composition of potatoes, 810.

chemical analysis, collecting samples for, Ga. 24.

clay mineral content, relation of parent material and environment to in Iowa, 783.

Clostridia in, occurrence, 25.

cobalt-deficient, in Australia, 169.

coffee, saving in Puerto Rico, U.S.D.A. 666.

## Soil(s)—Continued

- colloidal behavior, XXIV, Donnan equilibria in soil formation, 477.
- conservation and abuse, U.S.D.A. 311.
- conservation, book, 26.
- crystalline calcium silicate and "glassy" materials, carbonatation variance, 480.
- cultures—
  - modified Mitscherlich method, 782.
  - modified Neubauer method, 782.
  - pot method, equipment and operative technique, 781.
- DDT applications, effects on black beetle, 531.
- deficiencies, testing, choice of plants for, factor of photoperiodic response, 795.
- dispersed, freezing and thawing, effect on aggregation and permeability, 169.
- drifting across eroding fields, cumulative intensity, 172.
- elements, effects on food, symposium, 272.
- eroded, plant-growth conditions in relation to vegetative cover, 26.
- erosion—*see* Erosion.
- fertility—
  - decrease in Black Belt, effect on alfalfa, Miss. 786.
  - practices in war and peace, U.S.D.A. 581.
  - standards for game food plants, 520.
- fertilizer needs determination by leaf analysis, basis, 321.
- fertilizers balanced by tests for potassium and phosphorus in, 174.
- fluorine content, 788.
- forest, relation to growth, treatise, 630.
- formation, Donnan equilibria, 477.
- "glassy" and crystalline calcium silicate materials, carbonatation variance, 480.
- greenhouse, chemical disinfection, 61.
- gypsum as corrective and builder, Ariz. 28.
- Illinoise—
  - erodibility, 173.
  - organic matter in, erosion effects, 173.
- losses of nitrous nitrogen on desiccation, 479.
- Lufkin fine sandy loam, as influenced by plowing under hairy vetch, 196.
- management in Lower Rio Grande Valley, Tex. 476.
- microbiological activities, influence of incubation temperature, 785.
- minerals, influence on insects, 532.
- moisture—
  - deficiency, effect on leaf elongation and fruit growth of Deglet Noor date, U.S.D.A. 203.
  - measuring methods, compared, 170.
  - tensiometers, adaptation to field use, 170.
- molybdenum in, microdetermination, 152.
- nitrogen conservation in—
  - influence of time and plowing under legumes, 191.
  - legume management factors, 27.
- of Wasatch Mountains, properties, 784.

## Soil(s)—Continued

- organic and sandy, chemical relationships of potassium and magnesium in central Florida, 787.
- organic residues, effects on semiarid soil, 786.
- phosphate retention, 176.
- phosphate adsorption in Illinois, 175.
- plant relations, balancing, 174.
- plant-nutrient value, 28.
- potassium needs in New Jersey, N.J. 174.
- properties influencing use of land in West Virginia, W.Va. 476.
- reaction—
  - effect of sources of nitrogen, 786.
  - effect on blueberry culture, 53.
  - relation to toxicity and persistence of herbicides in greenhouse plots, U.S.D.A. 478.
- research—
  - by experiment stations, progress reports (1945), U.S.D.A. 142.
  - progress reports, U.S.D.A. 140, 142.
  - progress reports, Ala. 143.
- saline, heat resistance of cotton leaves, 36.
- saline, moisture-stress on roots in container, evaluation techniques, 171.
- sampling tube, 25.
- saturated, electrical conductivity, means of estimating soil solution concentration, 478.
- science, bibliography, 1940–44, 781.
- series and types, arrangement according to functions of soil-forming factors, 783.
- solution concentration, estimation from electrical conductivity of saturated soils, 478.
- straw mulch for improvement of, 173.
- structure, clay-mineral role in, 169.
- sulfur as corrective and builder of, Ariz. 29.
- survey—
  - in Tennessee, Lincoln County, U.S.D.A. 25.
  - reports, 1936 series, U.S.D.A. 312.
- temperature—
  - apparatus for recording, 108.
  - crop-residue effects, 27.
  - effect on development of rhizoctonia root canker of alfalfa, U.S.D.A. 822.
  - relation to development of armillaria root rot, Calif. 209.
- tensiometer design, improvements, 477.
- testing service increasing, Miss. 170.
- thermal relationships, apparatus for recording, 108.
- thermometers, field-type, 167.
- tillage—*see* Tillage.
- treating with 2,4-dichlorophenoxyacetic acid, effect on germination and development of seedlings, 320.
- treatments—
  - chemical, effect on development of wheat mosaic, Wash. 214.
  - effect on chemical composition of hay and forage crops, 481.

- Soil(s)—Continued  
 treatments—Continued  
 effect on soil productivity, summary of long-time field experiments, Ill. 632.  
 water relationships, apparatus for recording, 108.  
 yeast, lipid production by, 25.  
 Soil-air, displacement by  $\text{CO}_2$  for permeability tests, 785.
- Soil Conservation Service, report of Chief (1945), U.S.D.A. 26.
- Soilless culture for plant research, 783.
- Solanum nigrum*, Duvel buried seed experiments, final results, U.S.D.A. 201.
- Solar—  
 activity, relations with lower atmosphere, 473.  
 radiation, potato soft rot effects, 24.  
 variation, measuring, 166.  
 variation, weather effects, 166.
- Solvents—  
 for absorption spectroscopy, purification by adsorption method, 161.  
 industrial, compositions and trade names, 140.  
 rapid removal, apparatus, 298.
- Somatic chromosomes, root-tip smear method, use of enzymes, 793.
- Sorghum—  
 amylase, composition and traces in malt, 613-614.  
 Hodo, July-planted, for grazing beef cattle after frosts, unsatisfactory, Miss. 233.  
 midge, distribution, 77.  
 seed, subcoat, second factor, 798.  
 spp., ramulispora sooty stripe disease of, 69.
- South Africa, milk, solids content, 553.
- South America, agriculture, notes, U.S.D.A. 606.
- South Carolina Station, report, 1945, S.C. 909.
- Southern—  
 bean mosaic virus, purification and crystallization, 71.  
 corn rootworm, general study in Nebraska, Nebr. 83.  
 house mosquito, larvicidal action of DDT, factors in, 77.  
 pine bark beetles, informatory account, 84.  
 pine sawyer, informatory account, 84.
- Southern Great Plains Field Station, Woodward, Okla., chlorosis of grapes, Okla. 679.
- Sows—*see also* Hogs; Pigs; Swine.  
 estrus in lactating, induction by equine gonadotropin, 46.  
 feeding sardine condensed fish solubles and rye pasture during gestation and lactation, 845.  
 pregnant, feeding green food, effect on incidence of piglet anemia, 233.
- Soya products, edible, susceptibility in storage to attack by *Tribolium confusum*, Minn 836,
- Soybean(s)—  
 bud blight, caused by tobacco ring-spot virus, 212.  
 canned, chemical and nutritional studies, 882.  
 choline content, 273.  
 fertilizers, lime, potash, phosphate, N.C. 662.  
 infection by *Xanthomonas phaseoli* var. *sojense*, severity, relation to stomatal behavior, 339.  
 insects, control, N.C. 691.  
 lecithin, fatty acid components, 465.  
 lime spray repellents against Japanese beetle, 352.  
 meal, in dry calf starters with limited quantities of milk, Nebr. 237.  
 nitrogen fixed, yield and quantity, effect of straw and nitrogen, 811.
- oil—  
 content, determination, 621.  
 content, determination, effect of relative humidity, 469.  
 fatty acid composition, relation to iodine number, 460.  
 feeding to rats, resultant body-fat changes, off of dietary adjuvants on, Iowa 594.  
 solvent extraction from raw materials, bibliography, 457.
- oil meal—  
 autoclaving, influence on availability of cystine and methionine for chick, 817.  
 feeding to hens, effects on viability of progeny, 547.  
 in poultry rations, W.Va. 235.  
 phosphorus, availability for rat, 596.  
 phosphorus, utilization, enzymatic relationships, 596.  
 preharvest sampling for quality and yield, Iowa 199.  
 respiration, relation to moisture content and mold growth, 825.  
 sampling for analysis, 469.  
 varieties, abnormal swellings on stems, anatomy, 796.  
 varieties and planting dates in Yazoo Mississippi Delta, Miss. 503.
- Spanish-English glossary of forestry terminology, U.S.D.A. 667.
- Sparrow, English, blood parasites of eastern Washington, 525.
- Spectrophotometry—  
 gossypol assay by, 14.  
 rotenone and related compounds determined by, 14.
- Spectroscopy, absorption, solvents purified by adsorption method, 161.
- Spermatophytes—  
 Dominican Republic, book, 181.  
 Maryland, catalog, 180.
- Spermatozoa, bovine, livability and metabolism, effect of sulfanilamide, 496.
- Sphaceloma plantaginis* n. sp., cause of scab of plantain, description, 679.

- Sphagnum*, cellulose content, nature, 645.  
 Spicing pickles with imitation clove oil, 267.  
 Spider(s)—  
   of Great Swamp, preliminary list, 221.  
   of Iowa, studies, 527.  
   of Maryland, annotated list, Md. 527.  
   poison-squirting, note, 351.  
 Spinach—  
   dehydration, variety role in quality, 123.  
   injury from soil nitrogen and thrips, 225.  
   virus inhibitors in extract, 334.  
*Spiraea aruncus*, antibiotic isolation, 483.  
 Spirochetosis in turkeys, 399.  
 Spittle insects, control in strawberry plantings, 835.  
 Spittlebugs of Missouri, 221.  
 Spores, distance dispersion rates, 208.  
 Spray(s)—  
   adjuvants, polymeric organic polysulphides, 510.  
   application relations to leaf areas, 78.  
   DDT, dispersion from fast aircraft, 79.  
   effect on blooming of potatoes, 66.  
   for potato demonstration plots, 1945, N. Dak. 211.  
   herbicidal, water-soluble, glycerin as supplement, 314.  
   materials for potato—  
     early blight fungus, evaluation, N.Dak. 211.  
     insect pests, evaluation, N.Dak. 211.  
   new, in control of insects and diseases, 355.  
   oil, for weeding—  
     carrots, N.Y. State and Cornell 330.  
     carrots and related crops, Mich. 328.  
   residues, DDT in, analysis, 778.  
   xanthone residues in, colorimetric analysis, 156.  
 Sprayers for—  
   control of apple scab, 827.  
   dispensing concentrated insecticides, 831.  
 Sprouts—see also Seeds, sprouting.  
   legume and cereal, substitute for fresh vegetables, 266.  
 Spruce, Norway, cuttings, rooting, seasonal progress, 667.  
 Squab raising, U.S.D.A. 552.  
 Squash(es)—  
   bugs, immature, control, 693.  
   root aphids, 77.  
   skin, changes during storage, and relation to spoilage, 665.  
   summer, ascorbic acid, carotene, chlorophyll, riboflavin, and water content, 277.  
   winter, mottled-leaf character dominant, 187.  
 Squirrel, Mexican ground, life history, 683.  
*Stachybotris*, vitamin requirements, 484.  
 Stains—  
   biological, handbook on nature and uses of dyes employed in biological laboratory, 778.  
   Stains—Continued  
     standardization, progress, 779.  
     technique—  
       for bacterial counts in dried milk, 11.  
       for rubber in ground or milled plant tissues, 21.  
       virus isoelectric point determined by, 59.  
*Staphylococcus*(i)—  
   infection, enzootic, of lambs, associated with tick-bite, II, bacteriology, 563.  
   mastitis, culture characters, 98.  
 Starch(es)—  
   acid-hydrolyzed, production of 2,3-butanediol, 766.  
   determination in corn and wheat, improvements, 472.  
   determination, rapid, acid and enzymic hydrolysis methods, 301.  
   fractionating technique, 15.  
   fractions, iodine color, estimation, 772.  
   from potatoes of different culinary quality, physical properties, 412.  
   iodine color, estimation, 772.  
   pea, amylose content, 450.  
   rotation of dispersions, reversible effect of stannic chloride, 3.  
 Starvation—  
   human, and consequences, 886.  
   metabolism of oats leaves under, 184.  
 Statistical methods in chemistry, 1.  
 Statistics, experiment-station (1945), U.S.D.A. 142.  
 Stearic acid—  
   adsorption analysis, technique, 155.  
   preparation from castor oil, 611.  
 Steers—  
   beef, feeding value of corncobs and shucks, 547.  
   beef, selection, fitting, and showing, Fla. 233.  
   breeding for beef production, U.S.D.A. 41.  
   fattening on dehydrated potatoes and alfalfa silage, Colo. 704.  
   two-year-old, fattening on grass, supplements, progress report, 373.  
   two-year-old, wintering on grass, protein and mineral supplements, progress report, 373.  
   utilization of—  
     roughage and pasture, Mich. 703.  
     simple compounds of nitrogen, 231.  
     yearling, wintered at different levels, summer gains, progress report, 374.  
 Stem rust reaction, inheritance in barley cross, correlation with nitrogen content and kernel weight, 648.  
*Stemphylium*, Danish species, monograph, 60.  
*Stenocranus* spp. in America north of Mexico, taxonomy, 353.  
*Stenosphenus*, cerambycid beetles in America north of Mexico, synopsis, 221.  
 Stereochemical configuration and provitamin A activity, IV, neo- $\alpha$ -carotene B and neo- $\beta$ -carotene B, 615.

- Sterility, female, genes in dairy cows for, 187.
- Sterol production by *Aspergillus flavus-oryzae* and anti-rachitic potency, 430.
- Stickers, for lead arsenate sprays on fruit trees, Conn. [New Haven] 531.
- Stiff-limb disease, prevention and cure by vitamin E, 855.
- Stilbestrol—  
capon production by, 190.  
derivatives, feeding to chicks, effects on glands, body weight, and dressing appearance, 490.  
effects in retained placenta, 392.  
effects on pyometra following retained fetal membranes, 392.
- Stinkbugs, life history, 695.
- Stipagrass, "green, description and value, N.Dak. 656.
- Stockings—see Hosiery.
- Stomatitis, vesicular, virus of swine origin, 243.
- Stoneflies of Indiana listed, 80.
- Storage, short-time, effect on ascorbic acid content of grapefruit juice, 283.
- Stored products, beetles associated, monograph, 85.
- Storm ice, damage to hardwoods, decay following in central New York, 829.
- Straw mulch for soil improvement, 173.
- Straw, strength in small grains, [N.Y.] Cornell 803.
- Strawberry (ies)—  
ascorbic acid content, varietal differences, La. 899.  
breeding for high vitamin C content, N.Y. State and Cornell 817.  
freezing experiments in Louisiana, 881.  
growing in Washington, Wash. 203.  
marketing, experimental, Ohio 816.  
new varieties, N.C. 665.  
plantings, spittle insects, control, 835.  
virus complexes, resolution by means of aphid vector, *Capitophorus fragariae*, 678.  
weevil, insecticidal trials, 84.
- Strepogenin content of proteins, correlation with growth promotion, 449.
- Streptococci associated with subacute bacterial endocarditis, 791.
- Streptococcus*—  
*agalactiae*—see Mastitis.  
*faecalis*—  
amino acid requirements, 179.  
threonine assay by, 179.  
*lactis* R-stimulating factor, enzyme producing from inactive precursor substance in yeast, 614.  
s. b. e. strains—  
association with subacute bacterial endocarditis, 790.  
immunological characteristics, 790.  
synthesis of polysaccharide from sucrose, 790.  
spp.—see also Betacocci.
- Streptomyces griseus*, metabolism and chemical nature, 791.
- Streptomycin—  
absorption and excretion by dogs, preliminary studies, 248.  
activity, relation to bacterial spores and preservation of milk, 852.  
in avian malaria therapy, 107.  
properties, toxicological and pharmacological, 388.
- Striga* spp., parasitism on *Dolichos lablab*, 513.
- Strigoderma arboricola*, life history and habits, 689.
- Strongyles, sheep, gastrointestinal, action of phenothiazine on, 394.
- Strongylosis, pulmonary, in swine, 857.
- Strongylus vulgaris*, infestation of horses, 395.
- Stubborn disease of citrus, virosis, symptoms, 828.
- Sturgeon, lake, in Lake Winnebago, Wis., 76.
- Subtilin antibiotic produced by *Bacillus subtilis*, I, II, action and toxicity, 636.
- Succinylsulfathiazole, failure to aggravate egg-white induced biotin deficiency in rats, 429.
- Succinylsulfathiazole, feeding to rats receiving purified diets, 276.
- Succulometer, for measurement of maturity of raw and canned whole kernel corn, description and use, 770.
- Sucrose—  
acid inversion, 610.  
enzymatic synthesis of dextran, 765.  
in binary mixtures, estimation, 304.  
nutritive value of dextrose vs. in rats, 136.  
polysaccharide synthesis by *Streptococcus* s.b.e. strains, 790.  
synthesis by bacteria, mechanism and significance, 31.  
utilization, as influenced by thiamine in rats, 136.
- Sucrose-invert sugar mixtures, assay by copper reduction method, 15.
- Sugar(s)—  
acetyl groups in acetates of, microdetermination, 153.  
assay techniques, 15.  
conservation in ice cream, ices, and sherbets, 99.  
crops, research progress reports, U.S.D.A. 142.  
decomposition in dilute acid at high temperature, 21.  
hydroxyl content, microdetermination, 153.  
rare, utilization by micro-organisms, 178.  
reducing groups, measurement by Kiliani reaction, 620.  
wood, analysis methods, 153.  
wood, fermentation to alcohol, 162.
- Sugar beet(s)—  
bacterial blight, seed transmission, 673.  
cercospora leaf spot, epidemiology and control, Iowa 70.

## Sugar beet (s)—Continued

- curly-top virus, occurrence in meristematic tissue, 515.
- foliage, chlorosis and necrosis, causes, 673.
- growth for seed, damage by *Fuschiatus im-pictiventris* and *Chlorochroa sayi*, 834.
- harvester, trials in Michigan, 1945, Mich. 722.
- mosaic in New Zealand, 514.
- seed, shearing effects on labor, stand, and yield, Mich. 47.
- yellow wilt in Argentina, U.S.D.A. 826.
- yellows, serological investigation, 1942-43, 514.

## Sugarcane—

- borer, control by dusting with cryolite, 360.
- disease situation in Louisiana, 514.
- disease testing and initial seedling selection at Houma Station, 1945, U.S.D.A. 674.
- froghopper, insecticidal trials, 84.
- juice, constituents, isolation by chromatographic methods, 301.
- lands, weed control by 2,4-D, U.S.D.A. 811.
- noble, wild relatives, 323.
- response to hot-water treatment, La. 515.
- stomate differentiation in, 38.
- varieties, smut, effects during crop year 1944-45, 212.

## Sulfa—

- drugs, control of—
  - American fowlbrood, 544.
  - fowl typhoid infection, 568.
- treatment of American fowlbrood, 702, 840.

## Sulfadiazine treatment of man for anthrax, 242.

## Sulfaguanidine—

- effect on caecal coccidiosis, Del. 858.
- effect on course of infection in chickens with *Eimeria tenella*, 397.
- value, prophylactic and curative, in swine coccidiosis, 564.

## Sulfamerazine—

- prophylactic in pullorum disease in poult, 398.
- treatment of—
  - experimental cecal coccidiosis of chickens, 398.
  - pullorum disease, 568.
  - respiratory diseases of turkeys, 569.
  - strangles, 100.

## Sulfanilamide—

- cytological effects on *Allium cepa*, 324.
- effect on livability and metabolism of bovine spermatozoa, 496.

## Sulfate, titrimetric determination in natural waters and soil extracts, 771.

## Sulfathalidine in treatment of enteric infections of small animals, 248.

## Sulfathiazole—

- for turkey diseases, ineffectiveness, 569.
- medication for American fowlbrood of honeybees, 702.

## Sulfonamides—

- action on certain fungi pathogenic to man, 315.
- effect on growth of legume, 183.
- pharmacology, aspect, 854.
- recently developed, efficacy against fowl typhoid, 860.
- therapy, 853.
- toxicity, to chicks evaluated, 106.

## Sulfur—

- content in feeds, assay methods, 20.
- dioxide, content of—
  - dehydrated foods, determination, 155.
  - fruits, determination, 306.
- feeding to lambs, results, Colo. 856.
- in feeds, determination of total, nitric and perchloric acid digestion procedure modified, 156.
- soil corrective and builder, Ariz. 29.
- toxicity to livestock in combination with protein concentrates, 854.

## Sumac(s)—

- native species, tannin production, 322.
- tanning sheepskin skivers by, species compared, 164.

## Sunflower—

- new cultivated from Mexico, 812.
- seed and oils, 611.
- seed protein, value, 235.
- tissue cultures, growth in vitro, influence of composition of medium, 793.

## Sunlight intensities, effect on nitrate utilization by coffee plant, Hawaii 203.

## Sunscald, tomato seedlings, production by "flue dust," 845.

## Superphosphate, concentrated, mixing and curing effects on conversion, 176.

## Surgical instruments, sterilization, 386.

## Sweat—

- excretion of ascorbic acid and dehydroascorbic acid under different environmental conditions, 740.
- inositol and *p*-aminobenzoic acid occurrence, 710.
- of normal individuals, excretion of pyridoxine, "pseudopyridoxine," and 4-pyridoxic acid, 276.

## Sweet potato (es) —

- acreage and prices in Tennessee, Tenn. 112.

## ascorbic acid content—

- and carotene content, varieties and storage losses compared, Ariz. 131.
- effect of curing, S.C. 891.
- effect of fertilizers, curing, storage, and cooking, Ga. and N.C. 742.
- carbohydrates, changes occurring during dehydration, blanching, or baking, S.C. 878.
- carotene content, effect of—
  - curing, S.C. 891.

    - growth and fattening of broilers, 46.
    - mammary gland of rat, 46.

## Thiouracil—Continued

## feeding—

high levels, cause of perosis in chicks, 567.

to chicks, effects on glands, body weight, and dressing appearance, 499.

to hens, effect on thyroid gland of chicks, 234.

Thread, sewing, selection, Ohio 751.

Threonine, assay by *Streptococcus faecalis*, 179.

## Thrips—

greenhouse, injury to spinach, 225.

of Island of Hawaii, additions with three new species, 830.

Thunderstorms, thermodynamics, 167.

Thymine and vitamin B<sub>6</sub>—

*Lactobacillus casei* response, 159.

*Streptococcus faecalis* response, 159.

Thymonucleopolymerase, viscosimetric determination, 772.

## Thyroid—

desiccated, feeding to chicks, effects on glands, body weight, and dressing appearance, 499.

gland involvement in lowered fertility of rams, Mo. 800.

gland of rat, thyroxine content, determination, 771.

influence of—

rape seed in chicks, 46.

thiouracil in broilers, 46.

Thyroprotein, administration route, relation to utilization by ruminants, Mo. 372.

## Thyroxine—

administration route, relation to utilization by ruminants, Mo. 372.

determination in thyroid gland of rat, 771.

formation from diiodotyrosine, effect of experimental conditions, 449.

Thysanoptera, additions including three new species, Island of Hawaii, 830.

Tibet, marches, plant hunting, history of botanical exploration, 637.

## Tick(s)—

bite, lambs, enzootic staphylococcal infection, II, bacteriology, 563.

bite, lambs, enzootic staphylococcal infection associated with, 246.

collections at Army installations in Fourth Service Command, 700.

in New York State, address, 543.

repellents, garment spraying, observations, 839.

water balance, 229.

Tillage, rotary applications, 571.

Tillage, soil, rotary, 571.

*Tillus patagoniae* n. sp. from Arizona, description, 688.

## Timber(s)—

management program in northeastern Minnesota, Minn. 114.

requirements, forest management needs of postwar era and future, Miss. 667.

## Timber(s)—Continued

West Indian, physical-mechanical—properties, U.S.D.A. 669.

properties, II, U.S.D.A. 818.

## Tipula—

new species from western North America, 534.

three new species, descriptions, 687.

Tire cord, effects of temperature and humidity, 284.

Tissue extracts, citric acid assay in, 14.

Titration, conductometric, simplified apparatus, 10.

Titrimeter, description, 149.

## Tobacco—

alkaloids, physiological chemistry, recent concepts, development, 322.

blue mold in Georgia, 335.

bright, curing with coal and oil, Va. 723.

Connecticut 15, root-resistant type of shade tobacco, Conn. [New Haven] 602.

crop insurance in Tennessee, Tenn. 870.

diseases in 1945, Conn. [New Haven] 670.

Duval buried seed experiments, final results, U.S.D.A. 201.

excised tissue cultures, growth in vitro, influence of composition of medium, 793.

farms, credit in Puerto Rico, 1939-40, P.R.U. 727.

fertilization, role of boron, 788.

glandular leaf hairs, significance, 647.

Havana seed, black root rot resistant strains for Connecticut Valley, Mass. 812.

leaf proteins, effects of mosaic virus, 213.

leaf-burn, influence by content of potassium, nitrogen, and chlorine, 663.

marketing and manufacturing margins, U.S.D.A. 115.

mosaic, symptoms in *Nicotiana* spp., genotype and temperature relations, 39.

## mosaic virus—

at different stages of infection, electron microscope study, 674.

effects on leaf protein properties, 213.

fractions, ultracentrifugal examination, 340.

inactivation by potassium salicylate, rate, 213.

separation and properties in different states of aggregation, 340.

transmission through larvae of *Ptusia gamma*, 341.

## necrosis, virus causing—

purification and properties, further studies, 341.

ultracentrifugal examination, 341.

plants, infection by mosaic virus, effects on leaf proteins, 213.

ring-spot virus, cause of soybean bud blight, 212.

rosette, general study of virus complex and transmission, 71.

## seed oil—

analysis and fatty acid composition, 461.

## Tobacco—Continued

## seed oil—Continued

meal, protein content, nutritive value, 371.

nutritive value, 372.

seedbeds, sterilization by chloropicrin, Conn. [New Haven] 670.

seedlings, "frenching" due to isoleucine, 213.

statistics (1945), U.S.D.A. 116.

wireworm injury, influence of cover crops, Conn. [New Haven] 691.

yields, effects of lime, fertilizer, and preceding legumes, on Sango silt loam, Tenn. 803.

Tobacco research stations in India, notes, 760.

Tobacco Substation at Windsor, report for 1945, Conn. [New Haven] 662.

## Tocopherol(s)—

antioxidant activity, temperature effects, 6.

antioxygenic synergism in preservation of carotene, 743.

blood plasma, determination, simplified hydrogenation technique, 627.

chemical assay of total, in mixtures of forms, 19.

concentrates, by fractional crystallization of cottonseed oil from solvents, 458.

determination in plant tissue, 772.

effect on resistance of rats to anoxic anoxia, 739.

in animal fats, chemical determination, 627.

 $\alpha$ -Tocopherol—

chemical assay in mixtures of forms, 19.

pure, stabilizing agent for fats of poor keeping quality, 460.

 $\gamma$ -Tocopherol—

content in vegetable oils, assay, 160.

precursor of red quinoid substance developed in cottonseed oil during oxidation, 459.

*p*-Toluenesulfonamides, N-substituted, in codling moth larval control, 77.

## Tomato(es)—

Arkansas, production, canning, and marketing, 1940-41, Ark. 262.

ascorbic acid content at cannery, determination by field illumination and handling, 603.

bacteriostatic factor in fruits, 33.

big bud in, relation to yellows of kok-saghyz and aster, 210.

blight control in southwest Virginia, Va. 677.

brown root-rot, control by chloronitrobenzene, 676.

## canned—

by five home-processing methods, ascorbic acid value, La. 898.

in home, ascorbic acid losses, 898.

vitamin retention, effect of quantity preparation, 890.

## Tomato(es)—Continued

cannery, anthracnose control, two years' results, Mich. 677.

crop, good, essentials, S.Dak. 201.

diseases in Mississippi (1945), U.S.D.A. 58.

fall production, Miss. 815.

fruit rot, caused by *Phytophthora capsici*, epiphytology and control, 345.

fruitworm control, Utah, 693.

## fusarium wilt—

control by Dithane, 334.

relation to plant nutrition, 515.

juice, *D*-isoascrobic acid as antioxidant in, varieties compared, 72.

greenhouse production, improvement by use of 2,4-dichlorophenoxyacetic acid, Mich. 331.

guttation, effect of various ions, 506.

hormones, greenhouse tests, Minn. 202.

hybrid, superiority, Minn. 506.

juice, *D*-isoascrobic acid as antioxidant in, 124.

## late blight—

1946, U.S.D.A. 824.

in east Texas at transplanting time, 344.

on Florida west coast, U.S.D.A. 58.

resistance to fusarium wilt, interpretation, 515.

seedlings, sun scald, production by "fue dust," 345.

southern stem blight resistance of lines and varieties, Miss. 186.

varieties, ascorbic acid content and its retention in processed products, 603.

varieties for preserve making, comparison, 882.

vitamin C changes during home canning and storage, Ohio, 432.

Tongue deformity in chicks, amino acid-deficiency role, 105.

Tools, encyclopedia of mechanics', 108.

Torsion in protoplasm of myxomycete, 37.

*Torulopsis pulcherrima*—

culture study, *Taphrina deformans* compared, 61.

pigment production, effect of iron and other factors, 489.

Township zoning, case study, Mich. 734.

Toxicology, veterinary, Lander's, rev., treatise, 386.

Toxoid, alum-precipitated, control of enterotoxemia in lambs, 855.

Trace element deficiencies, multiple, in agricultural crops, 509.

Tractors, costs and use on upland farms, La. 116.

Trajectory technique, in weather forecasting, 22.

Traps, steel, substitutes for capturing wild-life, 829.

## Tree(s)—

Chinese-gallnut, general study, 57.

Christmas, species and culture comparisons, Ala. 57.

deciduous, defoliation, effects, 352.

- Tree(s)—Continued  
 diseases, epidemic, threat to shade trees in Michigan, 680.  
 drought effects, 167.  
 for Aleutian Islands, 181.  
 fruit—see Fruit(s) trees; also specific kinds.  
 heights, measurement by sectional pole, 667.  
 in prairie climate, ecological relations, 167.  
 in two climates, lecture, 779.  
 of Oklahoma, effect of chloride, Okla. 204.  
 planting machine, description, Mich. 109.  
 pruning by annual removal of lateral buds, 668.  
 radial growth at different altitudes, 817.  
 ring studies in North Dakota, N.Dak. 780.  
 solutions in, streaming movements, 642.
- Trefoll, birdsfoot—  
 characteristics and potentialities as forage legume, [N.Y.] Cornell 656.  
 propagation by root cuttings, 658.
- Tropiileus opuntiae* n. gen. and sp., description and occurrence, 680.

Utah College, notes, 446, 608.

Vaccine, *Brucella abortus* strain 19, agglutinin response relation to dosage and site of inoculation, 390.

Vaccines, swine erysipelas culture, validity, Nebr. 565.

Vacuator, dual use for condensing milk and pasteurizing ice cream mix, Oreg. 852.

Vacuum systems, control, simple automatic, 769.

Vanilla, curing, P.R. Fed. 162.

Varnish, bakelite, for honey extracting equipment, 702.

## Vegetable(s)—

ascorbic acid and carotene losses in large-scale cooking, Ala. 131.

blanching and cooling for frozen pack, 417.

blanching, electronic method, 125.

canned, drained and liquid portions, distribution of nutrients, 588.

canning cooperatives, status, 1943-44, U.S.D.A. 584.

carotene content—

physiological availability to rat, 598.

value for growth of white rat, 597.

crops, diseases in Florida, 335, 336.

dehydrated, nutritive value, oxidative enzymes, and other factors, 878.

dehydrated, sales and consumer acceptance in Grand Rapids, Mich., U.S.D.A. 872.

dehydration, varietal suitability, 122.

disease-resistant, lists, 675.

diseases in Georgia (1945), U.S.D.A. 58.

diseases on Florida east coast, U.S.D.A. 58.

farming, economic studies, New York, III, [N.Y.] Cornell 262.

freezing, home, 418.

importance of maturity, 881.

fresh—

harvested, ascorbic acid content, 602.

nutritive-value retention, 121.

shelf life, lengthening, Ohio 877.

freshness, preservation from harvest to consumption, 266.

garden, seed treatments in western Washington, Wash. 215.

gardener, handbook on insects and diseases, U.S.D.A. 505.

green, improvement of diet, Miss. 886.

Hawaiian-grown, iron availability, 595.

icing, effects on retention of quality and ascorbic acid, 895.

juices, growth factor, 819.

moisture losses during steaming, quick freezing, and packaging, 880.

plants, production, Mo. 201.

preservation, by sulfur dioxide solution, 126.

pressure-cooker gauges and, 125.

processed, Government inspection, questions and answers, U.S.D.A. 404.

Vegetable(s)—Continued  
production—

and marketing in Georgia mountain counties, Ga. 404.

glass plant protectors, Del. 664.

relation to freight rates in New Mexico, N.Mex. 869.

products and byproducts, 265.

protein-solution viscosity patterns, methods and comparisons, 2.

quantity cooking, vitamin retention, 277.

respiration, Pasteur effect, 492.

seed treatments—

1944, report by American Phytopathological Society, U.S.D.A. 674.

Oklahoma, Okla. 214.

seeds on sale in New York, 1945, quality, N.Y. State 333.

spoilage bacteria from, in home canning, 124.

storage organs, respiration, relation of anaerobic to aerobic, 492.

use in Hawaii, Hawaii 784.

vitamin C content, polarographic assay, 18.

vitamin P content, influence of chemical treatment, 749.

Vegetation, types, ground conditions, estimation from aerial photographic interpretation, 637.

## Vegetative cover—

analogs in Ukraine and Norway vs. U.S., U.S.D.A. 168.

eroded soils, plant-growth conditions, 26.

Veneer, checks, measurement method, 669.

Venezuela, policy measures and food production, 724.

## Ventilation—

electric, of poultry houses, 258.

forced in turnip storage bins, Ohio 862.

*Venturia pirina*, conidial pustules and role as necrotic canker foe, 73.

*Verbascum thapsus*, Duvel buried seed experiments, final results, U.S.D.A. 201.

## Vermont Station—

notes, 446.

report, Vt. 286.

Verticillium wilt of sainfoin, cause and incidence, 673.

Vetch, hairy, plowing under, effect on cotton yields and Lufkin fine sandy loam, 196.

Veterans, programs in rural areas, planning, [N.Y.] Cornell 264.

Veterinary miscellaneous papers, 558.

Virosis, genetic disease of white clover resembling, 39.

## Virus(es)—

crystalline plant, electron micrographs, 468.

diseases of plants and insect vectors, Hawaii, 820.

infectivity at various concentrations, theoretical study, 58.

investigations, value of serology for, 208.

molecular weights and other properties, determination by light absorption, 208.

- Virus(es)**—Continued  
 nature, general review, 483.  
 persistent and nonpersistent plant, transmission by same vector, 70.  
 proteins, isoelectric point, determination by stain technique, 59.  
 reproduction, nature, 59.

 leaf rust in Oklahoma and Texas, 336.  
 leaves, rust and phosphorus distribution, 674.  
 loose smut—  
   fungi in embryos, detection, 63.  
   incidence in West Virginia, seasonal U.S.D.A. 58.  
 mosaic, development, effect of chemical soil treatments, Wash. 214.  
 new variety—  
   beardless (Cadet), N.Dak. 200.  
   Vahart, Va. 200.  
 Oklahoma farm improvement program, progress report, 1938-45, Okla. 812.  
 plants, defoliation, artificial, effects, preliminary observations, 503.  
 resistance to hessian fly, relation to temperature, 224.  
 roots—  
   association with colonies of *Xanthomonas vesicatoria*, Ky. 214.  
   inorganic ions, absorption, transport, and exudation, 489.  
   rot, incidence, influence of time, rate, and depth of seeding, Wash. 214.  
 rust-resistant new varieties, 64.  
 × rye × *Elymus*, trigeneric hybrids, 649.

## Wheat—Continued

- Say stinkbug feeding, effect, 360.
- seed—
  - and seedling infection by *Xanthomonas translucens* var. *ccrealis*, 510.
  - quality, importance, [N.Y.] Cornell 813.
  - treated, effect of storage, 342.
  - "sick," development in sealed containers, factors affecting, 291.
  - spring, hessian fly infestation in south-western North Dakota, N.Dak. 360.
  - starch content, determination, improvements, 472.
  - starch, fat and phosphorus extraction, 3.
  - stem—
    - distortion, 827.
    - rust and yellow berry, 342.
    - rust fungus, physiological races in France, 512.
    - rust reaction, effect of DDT, 342.
    - sawfly attack, reaction of barley varieties, 688.
  - stored, thiamine content, observation, 281.
  - straw, furfural-yielding constituents, as influenced by sodium hydroxide solutions, 6.
  - substitutes, improvement of diet, Miss. 333.
  - take-all, etiology, 341.
  - technology, role of enzymes, volume, 762.
  - variegation in, maternal inheritance, 187.
  - varieties—
    - effect on maltose values, 813.
    - Illinois-adapted winter, Ill. 199.
    - North Dakota-adapted, N.Dak. 199.
  - viability loss, effect of fumigation and relation to baking quality, 813.
  - washing plants, fouling, prevention, 32.
  - winter, varieties for Oklahoma, Okla. 663.
  - yellow berry and stem rust, 342.
- Wheat grass(es)—
  - competition from cheatgrass brome, effects, 327.
  - crested, beginnings in North America, 807.
  - crested, production and utilization costs on wheat farms, Oreg. 112.
- Wheel bug, predator of Japanese beetle, 355.
- Whiptail in cauliflower and broccoli crops, control by ammonium molybdate, 512.
- Wild rice, Canada aphids on, 360.
- Wild rye, Mandan, description and value, N.Dak. 656.
- Wildfire return, Conn. [New Haven] 670.
- Wildlife—
  - capture by snares and deadfalls, 829.
  - of Texas, geographic distribution, 829.
- Wind—
  - abrasive and translocating actions, 172.
  - erosion—see Erosion.
  - indicators, dial, description, 309.
  - speed, experimental maximeters, 628.
  - transport capacity, 172.
- Windbreak planting at Akron, Colo., 37 years, Colo. 818.
- Wine(s)—
  - grape, vitamin B stability, 270.

## Wine(s)—Continued

- microorganisms, 884.
- monochloroacetic acid in, persistence, 8.
- Wings and ocelli correlated in insects, 78.
- Winogradsky, Sergei Nikolaevitch, Sept. 1, 1856–Aug. 31, 1946. great bacteriologist, 780.
- Winter—
  - fat, high protein content valuable in forage for Colorado ranges, Colo. 231.
  - hardening—see Hardening.
  - rainfall, foreshadowing in Florida and Montana, 23.
- Wireworms—
  - control, cultural practices and rotations in, 82.
  - control, ethylene dibromide and DDD mixture compared, 82.
  - injury to tobacco, influence of cover crops, Conn. [New Haven] 691.
  - investigations, 352.
- Wisconsin Station—
  - notes 288, 759.
  - report, Wis. 441.
- Wisconsin University, notes, 288, 759.
- Women—
  - clothing, tailoring techniques, for suit, U.S.D.A. 139.
  - college, nutritional status, relation to dietary habits, vitamin stores, Iowa 897.
  - Cornell University, dietary study, 885.
  - midwestern college, nutritional status, 590.
  - nutritive status, metabolism of calcium, nitrogen, and phosphorus, Iowa 880.
  - pregnant, diet, meat in, 885.
- Wood(s)—
  - natural resistance to termite attack, U.S.D.A. 696.
  - neotropical, lignin, ash, and protein content, P.R.U. 669.
  - preservatives, international test, progress report, 838.
  - preservatives, naphthenates of copper and mercury, 519.
  - saccharification—
    - kinetics, 21.
    - quantitative method, 162.
    - rotary digester, 22.
  - sugars, analysis methods, 153.
  - sugars, fermentation to alcohol, 162.
  - turpentine, steam-distilled content of gum spirits, detection and estimation, 470.
- Wood-boring insect, galleries, white deposit, composition and origin, 544.
- Wood-destroying fungi, alcoholic fermentation of carbohydrates and dehydrogenation of alcohols, 347.
- Woodland, invertebrates, abundance variations in Illinois, 350.
- Woodworking, handbook, 108.
- Wool—
  - and its upkeep, S.Dak. 433.
  - clip, 1944, marketing, Commodity Credit Corporation Purchase Plan, U.S.D.A. 728.

## Wool—Continued

fat, cholesterol separation from, 156.

laboratory, capacity increase by simple improvements, 285.

## Working conditions, rural—

construction of opinion scales, [N.Y.] Cornell 119.

opinions of university women, [N.Y.] Cornell 119.

Wound, vitamin C role in healing, 101.

Wyoming Station, report, 1943, Wyo. 605.

## X-rays—

effect on bone growth in pigeons, 47.

in combination with colchicine or acenaphthene, effect on plant tissue, 207.

irradiation, effects on genetic resistance of mice to mouse typhoid, 497.

*Xanthomonas*—

minimal nutritive requirements, 208.

*phaseoli*, association with common bean mosaic virus, II, III, 823.

*phaseoli* var. *sojense* infection of soybeans severity, relation to stomatal behavior, 339.

*translucens*—

parasitism on cereals and grasses, 62.

var. *cerialis*, infection of barley, bromegrass, and wheat, 510.

*vesicatoria*, growth and overwintering in association with wheat roots, Ky. 214.

Xanthone spray residues, colorimetric analysis, 156.

Xanthophyll, content in plants, determination, 154.

## Xanthurenic acid excretion—

factors affecting, 431.

in pyridoxine-deficient mice, as influenced by casien vs. tryptophan, 128.

*d*-Xylose, quantitative determination by selective fermentation, 302.

Yam bean, insecticidal resin of, constituents, 9.

## Yarns, cotton—see Cotton yarns.

resistance to insect pests, increase, compounds for, evaluation, 435.

## Yeast(s)—

baker's, activity and moisture content, effect of desiccation, 321.

chromosomes, staining by Feulgen technique, 616.

distillery, chromosomal behavior, 41.

effects of various chemicals, 633.

enzyme producing *Streptococcus lactis* R-stimulating factor from inactive precursor substance, 614.

genetics, review, 41.

growth, enhancement by nitrogen mixtures, 36.

growth, inhibition by tryosine-glycine mixture, 37.

## Yeast(s)—Continued

pigment production, effect of iron and other factors, 489.

preserved two years by lyophil process, viability, 321.

protein, nutritional value to rat and chick, 591.

soil, lipid production by, 25.

sugar utilization, rare forms, 178.

therapeutic effect on poikilocytosis in dairy cattle, 382.

vitamins, availability, I-II, 277.

## Yellow-fever—

## mosquito—

control by spray mists, 528.

feeding through animal membranes, 227.

life history and biology in South America, 87.

toxicity of DDT, affect of water, 224.

virus, hosts and vectors in two Brazilian forests, 219.

## Yellow—

mealworm, sodium metarsenite resistance, 85.

rust of raspberries, physiologic races in western Washington, 346.

scale, infestation coincident with soft scale, role of ants in, 77.

wilt of sugar beet in Argentina, U.S.D.A. 826.

## Yellows—see also specific host plant.

virus in sour cherries, expression, effects of temperature, 345.

Yolk, unabsorbed, in chicks, 551.

Youths, farm, not enrolled in school, N.C. 732.

*Zea mays*—see also Corn; Maize.

photoperiodism and sex, 649.

Zebu, roughage digestibility, crude fiber effects in cattle vs., 91.

Zein fibers, preparation by wet spinning, 764.

Zeisel methoxyl values for pectin, errors from retained alcohol, 154.

## Zinc—

flax deficiency in, 66.

phosphide poisoning, experimental, in fowls, 397.

toxicity in rats, antagonistic effects of copper and liver, 841.

value in dusts, trials, 821.

## Zinnia—

"root nodules" due to nematodes, 218.

seed, perithecia of powdery mildew on, 347.

Zoopagaceae, three new on soil amoebae, 315.

Zygnemataceae, from Louisiana and Texas, 180.

*Zygophiala jamaicensis* n. gen. and sp. description, 519.

Zygophyllaceae, bacterial root nodules. 639
